The amount of water available is limited and a new source will have to be found before many years if the town continues to grow as it has in the past, the population having nearly doubled in the last 25 years. As Wakefield is only about ten miles from Boston, it is probable that it will increase in size and also that it may be found desirable to enter the Metropolitan Water Works system with which a physical connection for emergency use now exists.

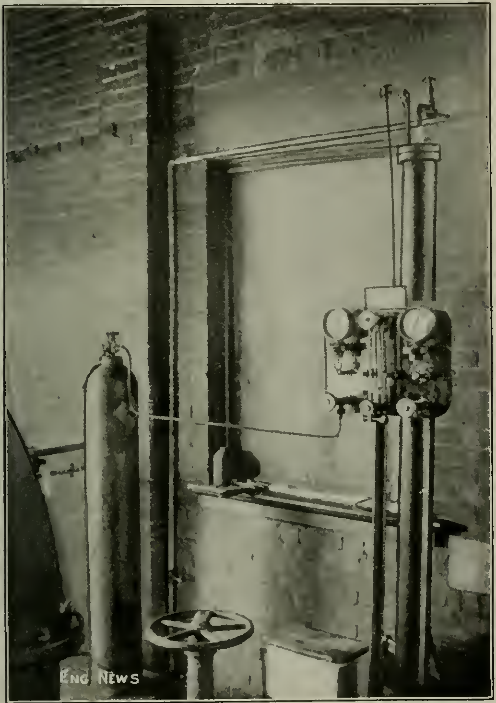
For this reason, and as the water of Crystal Lake is satisfactory in appearance, the town did not feel justified in constructing a filter plant, but the Water Board decided to continue its use provided it could be made safe at all times at not too great a cost. Upon the recommendation of the writer, it was decided to disinfect the water by chlorine gas and the necessary apparatus was installed.

The apparatus, which is shown in the illustration, consists of a gas tank, control board and absorption tower. The chlorine is received in liquefied form in steel cylinders containing about 100 lb. Opening the valves on the tank and the control board permits the chlorine to vaporize and the gas passes through the copper tube to the high-pressure gage on the right of the control board. It then passes through a pressure-reducing valve, the low pressure then being shown by the gage at the left side of the board, and after flowing through a rate-control valve, or

*Consulting Engineer, Boston.

ters the tower, behind the control board, where it is absorbed by a small spray of water. The chlorine solution is then allowed to flow into the pump suction, where it mixes with the supply and sterilizes it.

The rate of pumping is very nearly constant, the standpipe taking care of fluctuations in the rate of consumption, so that the rate of application of the gas is satisfactorily controlled by hand, by a tangent screw on the valve, the gage showing the amount being used in ounces per hour. The rate-control gage consists of a glass tube, ground on the inside to form a truncated cone, and a peculiarly



Liquid-Chlorine Installation for Water Disinfection at Wakefield, Mass.

shaped platinum float, which can move up and down in the tube. The gas, in passing upward through the tube, flows through the annular space around the float and raises it to the point where the area of the opening is sufficient. With a small flow the float remains near the bottom of the tube, while a larger flow raises it. Graduations on the glass make it possible to read directly the rate at which the gas is passing.

As a check on the rate of using the gas, the tank is placed on platform scales and the weight is read and recorded every morning when the gas is turned on and the pumps started.

The small tank near the base of the absorption tower is directly connected with it by a pipe and serves to maintain a supply of water at a fixed depth in the bottom of the tower, the tank being provided with a float valve. The water for absorbing the chlorine is supplied through a small pipe leading to the top of the tower.

During the first month of operation of the plant, chlorine was used at the average rate of 5.8 lb. per million gallons of water, analyses showing this amount to be required to effectually sterilize the water. This amount cannot be detected in the water by taste or smell. The results have been very satisfactory, the number of bacteria in the treated water being from 1 to 12 per c.c., except for a period of five days, when a reduced rate of application of the chlorine was tried, at which time the number of bacteria rose to an average of 22 per c.c.

The apparatus was installed by the Electro Bleaching Gas Co., of New York, and its operation is under the direction of the writer. The Wakefield Water Board consists of Charles A. Dean, Chairman, Dr. J. H. Kimball and T. G. O'Connell.

Annual Convention of the American Society of Municipal Improvements

The twenty-first annual convention of the American Society of Municipal Improvements was held in Boston, on Oct. 6 to 9. There was a good attendance, a full program of papers and committee reports, a number of interesting exhibits, a harbor excursion tendered by the City of Boston and a long automobile ride, the latter provided by the local committee.

By far the greater part of the program was devoted to roads and pavements. Next stood sewers and sewage treatment, and third came garbage and refuse collection and disposal and street cleaning. Fire protection and some general municipal problems were considered and there was one paper and a written discussion on bacterial limits for raw and filtered city water-supplies.

The notable achievement of the meeting was the adoption of a large number of standard paving specifications.

The papers and committee reports were too numerous for more than a wearisome categorical summary here, and will all appear in the annual proceedings of the Society. We shall therefore confine our report of the convention to the business proceedings, and chiefly to the action on standard specifications and forms.

In his brief presidential address, Edward H. Christ, of Grand Rapids, Mich., remarked that the convention then being opened was the first one since amalgamation with the Association for Standardizing Paving Specifications. Without doubt, he said, the greatest work of the society has been on standardizing specifications and report forms.

The report of C. C. Brown, Secretary of the society, showed an excess of about $740 in receipts over expenditures and a total membership of nearly 500. There were 239 active and 9 affiliated members; 30 municipal members, with 67 delegates; and 68 associate members, with 81 representatives.

Dayton, Ohio, was chosen as the next meeting place by a vote of 39, against 19 for New Orleans and 5 for Buffalo.

The president chosen for 1915 was Wm. A. Howell, Engineer of Streets, Newark, N. J. Charles Carroll Brown, Editor of "Municipal Engineering," Indianapolis, Ind., was reëlected Secretary.

Adoption of Standard Paving Specifications

For some years past the society has had a general committee and various sub-committees on paving specifica-

[illegible]. As a result, a number of paving specifications were submitted to previous meetings and some of them adopted by the Society. Working along the same general lines and to a considerable extent through the same men, the Association for Standardizing Paving Specifications, which held its last meeting in 1913, also adopted standard paving specifications. Since amalgamation, the paving specification committee and sub-committees of the American Society of Municipal Improvements have harmonized the two sets of specifications, made some revisions in them, and added others.

The general committee (Geo. W. Tillson, Consulting Engineer to the Borough President of Brooklyn, N. Y., Chairman) recommended the adoption of the following specifications, as submitted by sub-committees, with chairmen as stated in parentheses: Stone Block (H. H. Schmidt); Brick (E. H. Christ); Concrete (C. E. P. Babcock); Broken Stone and Gravel, the same with Bituminous Surface, and Bituminous Macadam (Prof. A. H. Blanchard); and Ashphalt (Francis P. Smith). This recommendation was adopted.

The general committee recommended and the meeting voted that the Wood Block specifications (Ellis R. Dutton, Chairman sub-committee) be printed; that the sub-committee be authorized to confer with the lumber and wood preservers' associations and that the specifications come up for action next year.

As to Bituminous [Concrete] Pavement specifications (Linn White, Chairman sub-committee) the general committee [illegible] and the meeting approved the recommendation of the sub-committee that the latter be allowed three months' time to draft and submit to the general committee two sets of specifications: one to follow the [illegible] patents and one to avoid infringement of these patents. The understanding was that if these specifications meet with the approval of the general committee, then they shall be accepted tentatively until the next meeting and come up for adoption at that time.

STANDARD SEWER SPECIFICATIONS

The same general committee (which is really one on Standard Specifications for all classes of municipal engineering work) also recommended the adoption of Sewer Specifications (F. J. Fort, Chairman of sub-committee) except that two sections shall be left open and alternates provided. This recommendation was adopted.

The reports of the general committee and the eight sub-committees on Specifications were presented and adopted in perhaps an hour and a half. A few questions were asked, to get explanations, but there was no discussion. In fact, Mr. Tillson stated, in effect, that discussion with the idea of changes from the convention at large, would not be fitting, since the various committees had given hearings for the very purpose of general discussion. The proper course, Mr. Tillson urged, would be to adopt the specifications and then for individual members to submit suggestions for changes during the year, if they so desired. [illegible] before many of the reports had been submitted, a resolution had been introduced which, if carried, would have postponed any action on the reports for a year, except [illegible] and printing them.

The society voted to print the specifications adopted, [illegible] to each member, and sell the remainder at [illegible].

REPORT OF COMMITTEE ON STANDARD FORMS

The chief progress made by this committee (J. C. Hallock, Deputy Chief Engineer, Newark, N. J., Chairman) was the submission through a sub-committee (E. S. Rankin, Chairman) of some forms for reporting sewerage operations. In accordance with the recommendations of both committees, a tabular form for reporting new construction was adopted and several other forms were ordered printed for consideration. Suggestions for conference with the Sanitary Section of the Boston Society of Civil Engineers, which adopted standard report forms some years ago, were not acted upon; but the one form actually adopted has no parallel in the Boston Society forms.

A sub-committee on Street Cleaning and Disposal (J. T. Fetherston, Chairman) reported that the poor success of the American Public Health Association in collecting statistics in accordance with the form devised by a committee of its Sanitary Engineering Section indicated that detailed data on street cleaning and refuse disposal are not available. The sub-committee presented a list of questions which it proposed to send out asking for information. Answers to these questions may be of immediate use as data, besides aiding in making up forms in the future.

NEWS NOTES

The Panama Canal Toll Receipts for September are reported to have been $117,[illegible]

Asphalt Pavement Contracts to the amount of $17[illegible] have recently been awarded in Richmond, Va.

A Highway Bridge collapsed under the weight of a heavily loaded furniture van, at Roxbury Mills, Md., Sept. 2[illegible]. The load is said to have exceeded that for which the bridge was designed. The bridge was about [illegible] years old.

A Collision between a passenger train on the Chicago & Eastern Illinois R.R. and a [illegible] truck loaded with [illegible] of nitroglycerin occurred at a grade crossing in [illegible], Ind., Sept. 21. One of the front wheels of the motor truck was torn off, but the nitroglycerin did not explode.

Ground Was Broken for the New East River Tunnels of the New York City subways from the Battery to [illegible] on [illegible] 11. The ceremonies took place at the foot of Whitehall St., and were attended by the Mayor, the members of the Public Service Commission and invited guests. The contractors are the [illegible] Engineering Construction Co. and [illegible] Flinn. The contract price is nearly $[illegible].

The Lakes-to-the-Gulf Deep Waterway proposed by the State of Illinois has been reported upon by the board of [illegible] engineers. [illegible] by which a [illegible]-ft. waterway may be built from Chicago to the Illinois River at La Salle. The recommended plan provides for the use of the Chicago Drainage Canal to Joliet, then of 15 miles of the Illinois & Michigan Canal to Illinois River. The estimated cost of this project is $[illegible].

Free Moving Picture Exhibits were given in the city parks of St. Louis during the summer months. Two wagons were sufficient to transport the entire outfit, including the [illegible] chairs used for the audience, from park to park. In this way 56 exhibitions [illegible] were given during the summer in [illegible] different parks. The expenses were within the appropriation of $[illegible]. It is proposed to continue the exhibit in the city school buildings during the winter months.

Paving Progress in Baltimore, Md.—It is reported that the Paving Commission will ask the board of Estimate for another appropriation of $[illegible] next year from the [illegible] loan. At the end of the present season, it is stated, the commission will have paved about [illegible] miles of streets since the new paving program was commenced in 1911. There is [illegible] part of the original $[illegible] which it was estimated would pay about half the cost of repaving the entire city. Another $[illegible] is [illegible] having the [illegible] the next [illegible] years.

New York Subway Construction Work continues to make satisfactory progress. There are now about 17,000 men engaged in construction work on the new subway and elevated lines. Contracts have been awarded for 59 of the 83 sections to be built. On some of the older contracts awarded in 1911 and 1912 the work is nearing completion and there are several stretches of completed structure in Lexington Ave., lower Broadway and Fourth Ave., Brooklyn. The Centre St. loop has been in operation some months. Work has recently been begun on the two-track Whitehall St. line, connecting the Broadway subway with the proposed new East River tunnels to Montague St., Brooklyn. Work has also been begun recently on both the new East River tunnels.

The Purchase of the Water-Works of the Spring Valley Water Co., San Francisco, Calif., will be submitted to popular vote next December, in accordance with action taken on Sept. 29 by the Board of Supervisors of San Francisco. The purchase is strongly advocated by City Engineer M. M. O'Shaughnessy, Mayor Rolph and the Advisory Water Committee.

The following estimates of values were arrived at after careful examination by City Engineer O'Shaughnessy and other experts in the employ of the city:

Physical properties	$13,922,534
Real estate in San Francisco	1,100,000
Lake Merced, 823 acres	1,647,340
Outside lands, 67,348 acres	6,734,800
Rights-of-way	520,000
Reservoir sites	5,022,072
Water rights	3,350,000
"Going concern"	2,500,000
Total	$34,796,746

The water company has agreed to accept $34,500,000 for its holdings. The acquisition of the water company's holdings by the municipality would end protracted litigation between the city and the company.

The Interstate Irrigation Commission held a preliminary meeting for organization at Helena, Mont., Oct. 1 and 2. Of the 16 arid and semi-arid states, nine were represented by delegates appointed by the respective governors. An organization was perfected with Ira P. Englehart, of North Yakima, Wash., as President; W. D. Beers, State Engineer of Utah, as Vice-President, and A. W. Mahon, State Engineer of Montana, as Secretary. It was agreed that the first regular meeting should be held in the City of Washington in December Various resolutions were introduced and discussed, but are to be acted upon at the next meeting, time being thus allowed for their full consideration. The most important of these resolutions looks toward the strengthening and unification of state laws regarding irrigation districts with a view to entering into contracts with the National government by which the present irrigation works built by the U. S. Reclamation Service may be turned over to the districts at the earliest practicable date and the funds thus released be used as soon as possible in building other works, and in completing some of the meritorious schemes begun and partly finished under the terms of the Carey Act, the state district and other laws. It is hoped by some such action to relieve the distress of the settlers on these projects and to overcome the general stagnation in the development of the resources of the arid West.

PERSONALS

Mr. E. B. Patterson has resigned as Engineer of the City Park Board of Dallas, Tex.

Mr. C. H. Blackman has been appointed Principal Assistant Engineer of the Louisville & Nashville R.R., with offices at Louisville, Ky., succeeding the late J. Werness.

Mr. L. E. Marshall has resigned as General Superintendent of the Illinois Northern Utilities Co., to become General Manager of the properties of the Missouri Gas & Electric Co., Lexington, Mo.

Mr. Harold Knight, former Division Engineer of the Erie R.R. at Jersey City, N. J., has been appointed Signal Engineer, with headquarters at Jersey City, succeeding Mr. W. H. Willis, resigned.

Mr. A. M. Acheson, recently Chief Engineer of the Missouri, Kansas & Texas Ry., at Dallas, Tex., has been appointed Superintendent of the Trinity district, with headquarters at Trinity, Tex. The office of Chief Engineer is abolished.

Mr. C. A. Thanheiser, Assoc. M. Am. Soc. C. E., recently Engineer of Maintenance-of-Way of the Missouri, Kansas & Texas Ry. of Texas, at Dallas, Tex., has been appointed Superintendent of the Smithville district, with headquarters at Smithville, Tex.

Mr. Charles F. Lacombe, F. Am. Inst. E. E., has resigned as Chief Engineer of the Bureau of Gas and Electricity of the Department of Water Supply, Gas and Electricity, New York City, effective Nov. 12. Mr. Lacombe has been connected with the department since 1903.

Mr. Harry Edward Prindle, formerly Canadian representative of Messrs. Palmer, Hornbostel & Jones, Architects, has opened an office at 915 New Birks Bldg., Montreal, Que., for the general practice of architecture. The Montreal office of Palmer, Hornbostel & Jones has been discontinued.

Mr. D. W. Chamberlain, for the past two years Resident Engineer of the California Highway Commission, has been promoted to be Assistant Division Engineer with headquarters at Fresno, Calif. Mr. Chamberlain was connected with the New York State Highway Department before going to California.

Mr. Frank Ringer, recently Superintendent of the Missouri, Kansas & Texas Ry., at Muskogee, Okla., has been appointed Engineer of Maintenance-of-Way, with headquarters at Parsons, Kan., to succeed Mr. L. F. Lonnbladh, promoted, as noted elsewhere. Mr. Ringer was Engineer of Maintenance-of-Way until a short time ago.

Mr. L. F. Lonnbladh, Engineer of Maintenance-of-Way of the Missouri, Kansas & Texas Ry., at Parsons, Kan., has been appointed Engineer of Maintenance-of-Way of the Missouri, Kansas & Texas Ry. of Texas, wtih headquarters at Dallas, Tex., succeeding Mr. C. A. Thanheiser, Assoc. M. Am. Soc. C. E., promoted, as noted elsewhere.

Mr. H. S. R. McCurdy, M. Am. Soc. C. E., Division Engineer in charge of the construction of the Ashokan Reservoir, Catskill Water Supply, has resigned as a member of the engineering staff of the Board of Water Supply, New York City, to go to Dayton, Ohio, with the Morgan Engineering Co., on the Miami River flood prevention work.

Mr. John P. Newton, Assoc. M. Am. Soc. C. E., Assistant Engineer, formerly in charge of the Bureau of Hydraulics, New York State Barge Canal, Albany, N. Y., has been granted leave of absence to become Engineer in charge of water supply investigations for the proposed new Pennsylvania canal system, with headquarters in Pittsburgh, Penn.

Mr. Elmer E. Bernard, Assoc. M. Am. Soc. C. E., formerly Assistant City Engineer of Lynchburg, Va., has resigned, effective Oct. 1, to become Engineer of Roadways of the Lynchburg Traction & Light Co. and the Roanoke Ry. & Electric Co. Mr. Bernard will divide his time between Lynchburg and Roanoke, Va., but will make his headquarters in Lynchburg.

J. H. Dockweiler, Consulting Engineer for the City Attorney of San Francisco, has been appointed by the City Council of Oakland, Calif., Municipal Water Expert, at a salary of $4000 per year. The appointment will not interfere with Mr. Dockweiler's consulting practice. He will be in direct charge of collecting data for rate suits and will represent the city in all water litigation.

Mr. John J. Long, for the past four years a member of the engineering faculty of Brown University, has been appointed Instructor in Civil Engineering in the University of Cincinnati, where he will teach sanitary and highway engineering. Mr. Long is a graduate of the Sheffield Scientific School, Yale University, and has been connected at various times with the Pennsylvania Lines West of Pittsburgh, the City Engineer's Office of Woonsocket, R. I.; the Bronx Bureau of Design, New York City, and more recently was Assistant Engineer in the Bureau of Highways, Borough of Queens, New York City.

Mr. A. B. Nichols, Office Engineer, under the Engineer of Maintenance, Panama Canal, has resigned and has returned to his old home in Philadelphia, Penn. Mr. Nichols was the oldest employee, in point of service, of the Panama Canal engineering staff. He was appointed to the canal service in May, 1904, and until June, 1905, was Assistant Engineer at Gatun. He was promoted to be Resident Engineer in the Culebra division, and in July, 1906, was made Office Engineer at Culebra, which position he has held ever since. Mr. Nichols was Division Engineer from 1899 to 1901 of the old Isthmian Canal Commission, and he had charge of the surveys for the Nicaraugua canal route.

Mr. C. J. Reilly, formerly General Superintendent of the Sandusky Portland Cement Co., and for the past year Consulting Engineer for the design, construction and operation of portland cement plants, with offices at Syracuse, Ind., has been appointed General Superintendent of the Sterling Portland Cement Corporation, a concern organized to take over and complete the plant started by the Seaboard Portland Cement Co., near Catskill, N. Y. This plant uses limestone

[illegible] shale and [illegible] originally designed and partly completed [illegible] the dry process. Mr Reilly proposes to redesign the entire plant to use the wet process, for the purpose of [illegible] [illegible] dust in the vicinity of the mill, and to make other [illegible].

Mr Frank W [illegible] M Am Soc C E, for many years Senior Associate Editor of "The Engineering Record" has opened consulting offices at [illegible] Broadway, New York City, and in the [illegible] St George Staten Island. Mr [illegible] is associated with Mr C F Fowler, M Am Soc C E, of Seattle Wash, and will specialize in bridge and structural steel work, foundations and general civil engineering and construction methods. He will also specialize in the preparation of engineering cases for litigation, expert witness reports and testimony preparation and mediation of cases in controversy and in the preparation of technical [illegible], popular and miscellaneous descriptions of engineering construction.

Mr Dwight B La Du, Assoc M Am Soc C E, former Division Engineer, Department of the State Engineer of New York, has been promoted to be Special Deputy State Engineer in charge of the Barge Canal work, to succeed Mr Alex F Kast M Am Soc C E, whose resignation was noted in these columns of Sept 24. Mr La Du has been connected with the Barge Canal work since its beginning with the running of precise levels in the Mohawk Valley in [illegible]. Later he was Assistant Engineer in charge of the construction of locks and canal in the vicinity of Whitehall, N. Y., and on the Champlain division of the Barge Canal. More recently he has been Division Engineer of the Eastern division, with headquarters at Albany, N. Y.

OBITUARY

Michael V Kennedy, a well known public-works contractor of Des Moines Iowa died Sept 2[illegible]. He was born in Ireland in 18[illegible].

Henry N Hamilton, a retired civil engineer, died Oct 7, at his home in Yonkers N. Y., aged 6[illegible] years. He was a great-grandson of Alexander Hamilton, of Revolutionary fame.

ENGINEERING SOCIETIES

COMING MEETINGS

AMERICAN ELECTRIC RAILWAY ASSOCIATION
Oct 12-16. Annual convention at Atlantic City, N J. Secy, E B Burritt, [illegible] West [illegible] St, New York City.

AMERICAN RAILWAY BRIDGE AND BUILDING ASSOCIATION
Oct [illegible]. Convention at Los Angeles, Calif. Secy, C A Lichty, [illegible] North [illegible] Ave, Chicago, Ill.

INTERNATIONAL ASSOCIATION OF FIRE ENGINEERS
Oct [illegible]. Annual convention at New Orleans. Secy, James McFall, Roanoke, Va.

AMERICAN GAS INSTITUTE
Oct [illegible]. Annual meeting in New York. Secy, George G. Ramsdell, [illegible] W [illegible] St, New York City.

[illegible] ROAD CONGRESS
Oct [illegible]. Congress at Milwaukee, Wis. [illegible], Milwaukee, Wis.

AMERICAN INSTITUTE OF ARCHITECTS
[illegible] Convention at Washington, D. C. Secy, [illegible] Washington, D. C.

AMERICAN MINING CONGRESS
Dec 7-11. Annual meeting at Phoenix, Ariz. Secy, J F Callbreath, Denver, Col.

NATIONAL SOCIETY FOR THE PROMOTION OF INDUSTRIAL EDUCATION
Dec 9-12. Convention at Richmond, Va. Secy, C A Prosser, 1[illegible] W [illegible] St, New York City.

SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS
Dec 10-11. Annual meeting at New York City. Secy, D H Cox, 2[illegible] W 3[illegible]th St, New York City.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS
Dec 2[illegible]-30. Annual meeting at Madison, Wis. Secy, F M White, Madison, Wis.

Engineers' Club of Jefferson City, Mo.—This club was recently organized with 31 charter members. H F Shaw, a member of the Missouri Public Service Commission, is President.

Indiana Electric Light Association—The annual convention was held in Indianapolis Sept 24 and 25. The following officers were elected: President, T E Grover, Terre Haute, Ind; Secretary, Thomas Donahue, Lafayette, Ind; Treasurer, Fred L Dennis, South Bend, Ind.

Conference of Mayors on the Regulation and Control of Public Utilities—Mayor Blankenburg, of Philadelphia, has invited the mayors of 75 large cities to meet in Philadelphia Nov 12, 13 and 14 to discuss public policies in regard to the municipal regulation and control of public utilities. The scheme has the indorsement of the mayors of New York City, Chicago, Cleveland and Dayton. The American Academy of Political and Social Science is coöperating with Mayor Blankenburg.

American Society of Mechanical Engineers—The nominating committee consisting of John E. Sweet, Charles Whiting Baker, John H Barr, A M Hunt and F W Gates have made the following nomination of officers for the coming year: For President, Dr. John A Brashear, of Pittsburgh, Penn; for Vice-Presidents, Henry Hess, of Philadelphia, Penn, George W Dickie, of San Francisco, Calif, and James E Sague, of Poughkeepsie, N Y; for Managers, Charles T Main, of Boston, Mass, Spencer Miller, of New York City, and Max Toltz, of St Paul, Minn, to fill the unexpired term of the late Alfred Noble, Morris L Cooke, of Philadelphia; for Treasurer, Wm H Wiley, of New York City.

Philadelphia Association of Members of the American Society of Civil Engineers—The [illegible] meeting was held Oct 5 with Hunter McDonald, President of the American Society of Civil Engineers, was a guest. The fundamental principles of the proposed federation of engineering activities in Philadelphia were approved by the meeting. The tentative draft of an act prepared by the Engineers' Commission of Pennsylvania for licensing engineers in that state was discussed. The Philadelphia Association was formally organized less than a year ago with 2[illegible] members. The membership has now reached 1[illegible] and the interest shown in the meetings indicates that it fulfills the purpose for which the association was organized.

The following officers have been elected for the ensuing year: President, Richard L Humphrey; Treasurer, [illegible] M Smith; Secretary, W L Stevens.

REVIEWS AND NOTES

How Can Engineers Best Utilize the Technical Journals?*

By John W. Alvord†

That we cannot keep abreast of the times without reading the engineering journals is obvious. That if we carefully read all the engineering journals in our chosen specialty we would have no time left to earn a living is easily capable of demonstration. What, then, is the proper attitude to adopt toward this ever increasing flood of information that pours in upon us so relentlessly?

The problem of the engineer with his technical paper is much affected by his age, station, and aim in life. To the man who is in engineering only to get money and more money, the engineering journal is a newspaper, in which he may notice mainly where there are better jobs than his own that may be sought after and perhaps obtained. To the man who is anxious to fit himself every year of his life for something better, it is an opportunity, quite unequaled many years ago, for a great variety of study. To the young engineer, the engineering journal, properly read and noted, is part of a post-graduate course in engineering. To the middle-aged man, it is a mine of data, bearing in all sorts of ways on his work, and to the mature specialist only does it begin to become burdensome by its repetition of experience, and its volume of matter on subject which has already, to him at least, been well digested.

Let us see if we can outline how each of these classes can get more profit out of the matter contained in the engineering journals than do the careless or the indifferent who, after their journal is once looked over, let it go to waste or idleness.

The young engineer should, as early as possible, take at least one good first-class engineering journal, and own it himself; bind it, if he can afford to, but lay it away in an orderly manner, in any event. If he can afford two journals, so much the better, especially if they are selected so as to widen his outlook. If one might advise, it would be to suggest enforced systematic reading of all articles particularly bearing on the line of work the reader is immediately engaged upon, and the optional reading only of such other articles as interest him.

It is probably not wise for the young engineer to indulge extensively in card indexes, filing systems, and the like, for topically arranging his available engineering journal articles. Few men know very early in life where fate and interest will land their future attention, and filing systems and special indexes are expensive and time consuming, and when indulged in without definite aim nearly always quickly become too voluminous and thereby useless. Many a young engineer has spent many weary hours filing and indexing only to abandon his system later or in despair at the quantity of material he early collects and the difficulties of making it quickly available.

If any suggestions are made along this line, it would be to start a loose-leaf letter-size (8½x11-in. page) notebook, and note in it (separate pages for separate subjects) only what appears to be extremely useful, either in exceedingly brief abstracts from engineering articles or diagrams, costs, etc. These notes will be most useful if they are confined to that kind of work in which the compiler is immediately engaged, and has on his mind at the time, or at the most, work very similar to his own, which has perhaps had his personal inspection.

If any such book is started, it is highly desirable that it be of letter size, because that is nowadays the working size to which all sorts of documents, engineering reports, and estimate work are approximating. Pocket notebooks, card indexes and odd sizes of notebooks should be avoided, if possible, as likely to be finally abandoned. The letter size fitting the stock office furniture and ordinary typewriter is much more likely to endure with the average man as a permanent system.

We next come to the man in early middle life, actively engaged in his profession, and note at once that his problem with the technical journal is the absence of "time." If he is largely engaged in administrative work, or is a salaried officer in a large enterprise with a comparatively limited range of problem, or a limited call for miscellaneous data, he may generally be content with a cursory examination of the engineering journal such as will keep him qualified on his undertaking, and the preservation of such journals in bound form, with the standard published indexes. If, however, he is entering upon novel work, or work presenting a great variety of problems, overlapping into a great variety of fields, ambition will compel him to do more than this, and some form of special indexing will appeal to him more or less strongly as he feels the need more often for research in uptodate material.

There are several methods of classifying and indexing selections from engineering literature which such an engineer may adopt.

(1) He may rely on his memory and the published index to his bound volumes.

*Extracts from a paper read at the meeting of the Federation of Trade Press Associations, at Chicago, Sept. 25, 1914.
†Consulting Engineer, Chicago, Ill.

It is safe to say, however, that few engineers really make much practical use of this method. The intervening index and the bother of a search following, prove to be discouraging to that degree that a proposed reference search is abandoned in about one-half the suggested attempts. The ideal filing system is the one in which with the least amount of effort one can put his hand immediately and accurately on the thing itself, be it a book, a pamphlet, or a data sheet.

(2) He may keep a special card index of important data, and reference to valuable articles.

This at once involves labor and attention, which few busy men can give, and which, if done by assistants or librarians, largely loses its personal value to the one who needs it. The same objection as to the discouraging effect of intervening indexes holds good here, too, and it is further safe to say that of all the contrivances for indexing, the most difficult to readily handle and rapidly examine is the card-index system.

(3) He may abstract important data in a limited way on loose-leaf transparent paper, standard letter size, and he may remove or detach articles of special value from out his journals, to be filed in regular office file system, like correspondence.

The writer has tried all of the above methods at considerable cost in time and patience, and has, for many years, settled upon the third method above outlined. With all its admitted limitations it seems to be the best for an office which is expected to find out information on a great variety of subjects in a limited time, and with the least amount of effort.

Some description of its practical workings may be of interest.

All the technical papers of the office pass on to the desk of the head of the office and are at least looked over (not read) by him. Articles important to his particular specialty are checked with pencil, and articles of especial interest are looked over with care and double-checked. Once in a long while data important enough to go to the data file are noted. This is either especially abstracted by the stenographer, or, if a diagram or road data, perhaps traced in the drafting room, all on transparent paper for copying purposes. Special data of this kind on standard-size sheets are filed in the office data file in separate but common standard correspondence size. From the data file loose-leaf working notebooks are made up from blueprints for office or travel purposes. They are altered, refilled, discarded, and sorted back from time to time as needed to keep them of usable volume and usefully up to date.

The technical journals with checked articles, go to the office clerk or the stenographer at odd hours, or the librarian if one can be afforded, and the useful articles are removed by tearing them out with a ruler. They are folded, usually once, to standard size, with one edge lap left for binding, and are then filed in a subject index file, like current correspondence. The Dewey decimal system, especially arranged for the office, is used, but only as a general subject plan. When the file is full, portions of its contents, especially that which is most useful, are simply bound in plain pasteboard covers and placed in the library shelves, with titles. Such a book for many subjects would contain all the recent articles thought to be of special value on a given single subject. The remaining portions of the technical paper are thrown away, but in a large office warranting the expense duplicate bound copies can be kept as well, with the general published index as their key.

The objections to this system are as follows:

1. It is too expensive for any but the most important offices doing specialized work.

2. [illegible] unless rigidly kept down to a minimum.

3. It requires some personal attention of the head of the office, a competent assistant or the employment of a regular librarian.

The advantages are:

1. It compels the office head to know all the time what is being published in current engineering literature, if only in [illegible].

2. It removes all intervening indexes between the searcher and the final repository in the bound volume.

3. It keeps [illegible] up to date on all lines in which one should be especially interested.

4. It is economical of [illegible] and thinking cost.

We come finally to the mature and experienced engineer of advancing years. How can he make engineering and technical literature of use?

It is safe to say that when an engineer has much passed fifty or sixty years of age, and has led an active life, in constant touch with affairs, he feels less need for accumulated data or particular description. Probably no one enjoys engineering reading as does the mature engineer, for he can read between the lines and find much to instruct as well as interest.

If his acquaintance is wide, he reads with interest the accomplishments of his friends, and the addresses of society presidents, and articles on the ethics of the profession. Of failures he is the keen student. The personal column appeals to him, and if he is of right-mindedness he is conscious of more pleasure than formerly in the accomplishments of those who have succeeded and succeeded well in dire and burdensome responsibility.

The engineering journal again becomes for him a technical newspaper of great personal interest and deep satisfaction, for no longer is he keen for jobs, or eager for data, but the human, personal, and ethical side of the life work of the engineer is uppermost in his mind, and he realizes that though he may have seemed to others, and even may have seemed to himself to have been striving all these years for emolument, as a matter of fact the deep and abiding motive of his life work has been the pleasure of being *needed* and the joy of being useful.

In conclusion, I would remark that technical papers, along with the technical societies and their proceedings, form the repository of the profession; they are the interchange of experience, the common store upon which we all draw. Without them we would be strangely helpless. We are indebted to everyone more or less who records his experience for the common use, and that debt we should endeavor to helpfully repay in kind, but wisely, concisely and thoughtfully.

Translation of Melan's Arches and Suspension Bridges

REVIEWED BY PROF. J. P. J. WILLIAMS*

THEORY OF ARCHES AND SUSPENSION BRIDGES—By J. Melan, Professor of Bridge Design, German Technical School at Prague. Authorized Translation by D. B. Steinman, Professor of Civil Engineering, University of Idaho; author of "Suspension Bridges and Cantilevers." Chicago: The Myron C. Clark Publishing Co. London: E. & F. N. Spon, Ltd., 57 Haymarket. Cloth; 6x9 in.; pp. x+303; 119 illustrations. $3.

This book is a complete literal translation of J. Melan's mathematical treatment of the elastic theory of arches and suspension bridges, as published in 1906, in Vol. 2, Part 5, of the German "Handbuch der Ingenieurwissenschaften." The translator states in the preface that admiration of the work of Melan and a desire to fill a gap in our own engineering literature on this subject were the impelling motives for the translation, and that he believes it will prove useful to practicing engineers and to teachers as a textbook for graduate work. He says: "The book will prove a liberal education in itself, rendering clear the fundamental principles of the analysis of structures, familiarizing the student with many helpful analytical and graphical devices of general application, training him in the independent derivation of formulas, and preparing him to do original work in structural theory and design."

Even after making full allowance for the natural en-

*[illegible], N. Y.; lately Assistant Professor of Structural Engineering, University of Minnesota.

thusiasm of an admirer, such a statement of the value of this book is quite evidently unwarranted. In order to justify such claims, a book on this subject should possess two definite characteristics: clear statement of notation and completeness in mathematical derivations. The book is defective in both. In order to be easily and effectively useful to both practicing engineer and student, the notation used in the many complicated formulas should be completely and clearly defined. In this book it is generally quite difficult to find the meaning of the symbols used because in nearly all cases they are defined in the body of the text, and no complete tabulated standard notation is given. In fact, in at least one case (Equation 416) the same symbol (A) is used in two entirely different ways, and often the symbols in a formula are defined after the formula is given.

The second noticeable defect is the incompleteness of the explanation and detail of the mathematical derivations. In a handbook, it is only necessary to give a concise statement of general processes and the final forms of working formulas. But for the engineer or student who really desires definite understanding of all formulas and completeness and certainty in their derivation, the book will be found to be quite unsatisfactory. Many hours of time would be required to check the mathematical formulas independently and repeat the author's omitted operations in order to confirm the accuracy of the formulas given. If mathematical gymnastics with the object of attaining a given result be the best training for engineering students, then the translator's claims for the advantages of this book as a text for graduate students are fully justified. In too many cases simple explanatory sentences stating the logical reasoning processes in detail are conspicuous by their absence, making the intelligent understanding of the mathematics unnecessarily difficult.

Aside from the defect of notation already mentioned, the book will be found most complete and useful as a reference work for formulas and both analytical and graphical methods of analysis of nearly all forms of both framed and solid arches and braced chain and cable suspension bridges. The author has undoubtedly accomplished an excellent piece of work requiring an immense amount of time and labor and great mathematical ability. It is by far the most extensive theoretical study of this subject known to the reviewer. The only incompleteness of treatment is in the theory of the continuous arch, which is not extended to include fixed ended continuous arches so extensively used in this country.

Although it has been impossible to find the time to study fully the accuracy of the translation, it appears to be both complete and exact with the exception of the translation of the word "berechnung." For example, Article 2 is headed "General Method of Design," and should be "General Method of Analysis." With this exception, the work of translation seems to be very well done.

The contents of the book are divided into five well defined sections: A—The Flexible Arch and Unstiffened Cable; B—The Stiffened Suspension Bridge; C—The Arched Rib; D—Arch and Suspension Systems with Braced Web; and E—Combined Systems. The Appendix discusses the application of the elastic theory to masonry and concrete arches, and contains short remarks on the temperature variation in steel and masonry bridges.

Section A contains two articles, one on the funicular polygon for vertical concentrated loads, continuously distributed loading and uniform loading, the other on the unstiffened suspension bridge. The latter (Art. 4) is divided into five parts, treating: (1) Form of cable and value of horizontal tension for chain (or eye-bar) cables and wire cables, and values of cross-sections required; (2) maximum attainable span, with table for various cases; (3) economic ratio of rise to span, including an example; (4) deformations and deflections under uniform loading, also effects of elongation of cable, displacement of saddles, and an example in metric units; and (5) secondary stresses due to friction at pins of eye-bar chain cable and example.

Section B, on the stiffened suspension bridge, contains five articles. The first of these, Article 5, contains the formulas for bending moments and shears in stiffening trusses, for the horizontal tension, and discusses influence lines and gives an example; this analysis being by the approximate method which neglects the effect of the deflection of the cable. Article 6 contains the expressions for values of horizontal reactions, and Article 7 the discussion of stresses in the stiffening trusses, including reaction locus, influence lines and graphical equilibrium polygon methods, effect of temperature and secondary stresses. Article 8 gives values of deflections due to loading and to temperature changes, and Article 9 contains the development of the more exact theory of the stiffened suspension bridge, with examples in metric units showing that the error resulting from the approximate theory might be a high percentage on the side of safety when light stiffening trusses are used.

Section C, on the Arched Rib with Solid Web, contains 19 articles fully developing the elastic theory of arch analysis. The first five articles discuss internal stresses in curved ribs, conditions for stability, line of resistance, core-points, graphic determination of normal fiber stresses, determination of deformations, external forces on arched rib, the reaction locus, tangent curves, and critical loading for maximum normal stresses and shears. These general formulas are then extended to apply to five different types of arch: (1) Three-Hinged Arch; (2) Arch with End Hinges; (3) Arch without Hinges; (4) Cantilever Arch; and (5) Continuous Arch. The last two articles then discuss the more exact theory of the arch, including the effect of deformation, and formulas for proportioning the section of plate-girder types of arch ribs.

In section D, the subject of framed arches and suspension systems is discussed in six articles. The treatment includes the determination of maximum stresses in members, the drawing of influence lines for three hinged and two-hinged arch frames, arch frame with tie rod, the free-ended cantilever arch, cantilever arch with ends fixed on horizontal rollers, framed arch with fixed ends, and the continuous-framed arch and braced-suspension bridge of multiple span. The example given as an illustration of the last mentioned analysis is Lindenthal's project for the Quebec Bridge, which is really an inverted two-hinged braced arch of three spans swung from rocker arms and anchored at the ends. All maximum stresses are determined, but using metric units.

Section E, on Combined Systems, contains two articles, one on the combination of an arch with a straight truss, and the other on the combination of the arched rib with a cable. The Appendix, already described, the very com-

[illegible] bibliographic and a rather meager index complete the volume.

On the whole, the typography and figures are perfectly satisfactory. In some formulas the Greek letter alpha looks almost exactly like "a," and sometimes the bold-faced symbols are not sufficiently distinct. In at least one formula there is an evident typographical error (Formula 175, "a" should be "A"). In a few figures the lines are crowded, and in Plate 1 some of the German notes and letters were not translated, but otherwise the publishers have done excellent work.

Rock Tunneling

Reviewed by F. Lavis*

MODERN TUNNELING, with Special Reference to Mine and Water-Supply Tunnels—By David W. Brunton and John A. Davis. New York: John Wiley & Sons. London: Chapman & Hall, Ltd. Cloth; 6x9 in.; pp. vi + 450; 80 text figures. $3.50, net.

Recently in conversation with a group of well known and quite prominent engineers, the question was raised as to the utility of books dealing with such phases of practical work as, for instance, that of tunneling, and the opinion was expressed that as far as tunneling or work of a similar character was concerned, they would rather take the opinion of an experienced foreman or superintendent, that is of the practical workman, than anything to be found in books.

The writer has had enough practical experience to have a good deal of respect for the opinion of the intelligent, practical man, but he has felt for many years that in regard to tunneling this had been carried rather too far in the United States. This may be one of the reasons why, up to within, say, six or seven years ago, the Europeans were so far ahead of us in this class of work, which has there been almost entirely directed by engineers and here by foremen. Since engineers in this country have taken an active part in the analysis of the causes which make for rapid progress and low costs and in the active direction of the work, we have done much better here and in many respects equaled or bettered European records.

Some seven or eight years ago, the writer was asked to review the book on tunneling, written by the late David McN. Stauffer. This was really a compilation of a number of descriptive articles previously published and scattered through a number of technical papers and periodicals, and while the reviewer admitted the fact that such compilation had a certain value, he expressed the opinion that there was a great need of a book on tunneling which would thoroughly discuss the relative value of modern appliances and the reasons for the (at that time) very poor showing (of progress) in American tunnels (as compared with European).

The introductory chapter of the book under review, which set forth its scope, warranted the expectation that this need had now been met, and it is a pleasure to say at once that this expectation has been realized. The introduction states that descriptions of work done are interesting historically, but that in very few of the published descriptions "do the writers attempt to criticise the methods [illegible] [illegible] [illegible] methods and [illegible]." In this volume, on the contrary, the authors state that the "[illegible] of each method will be a primary consideration" and that constructive rather than destructive criticism will be their object. "For that reason emphasis will be placed upon safe, efficient and economical methods and upon good points of equipment, while bad practice and obsolete machinery will be ignored except, perhaps, as examples of the inadvisable or as they have some bearing historically. Thus the authors hope to set forth a guide for future work rather than an unilluminated record of past or present achievement."

The authors have confined themselves entirely to descriptions of and the discussion of methods, applicable to mine adits and small tunnels, "where the entire cross-section is excavated in one operation," and practically entirely to excavation in solid rock. This, of course, limits the scope of their work and it would seem that the book might appropriately have been entitled, Modern Rock Tunneling as Applied to Mining and Small Water-Supply Tunnels.

The first three chapters, pp. 1 to 53, are devoted first to an introduction and a statement of the purpose of the authors, second to a brief history of tunneling from the earliest beginning to modern times, and which rather strangely includes the only reference and data in the book referring to railroad tunnels, and the third, contains some data of modern mining and water tunnels, including, of course, the tunnels of the Catskill and Los Angeles aqueducts (though the former are larger than those to which the subsequent discussions refer), the Newhouse, Laramie Poudre, Carter and others well known to those who keep in touch with this subject.

Chapters 4 to 14, however, contain the matter of greatest interest. Chapters 4 to 10, pp. 53 to 207, contain descriptions of and discussions of the value of various types of machinery, power plants, compressors, tunneling machines, drills, cars, ventilation methods, etc., etc. There are many tables and the advantages and disadvantages of the many different varieties of equipment, and their particular application to various conditions are very fully and intelligently analysed.

In chapters 11 to 14, pp. 208 to 274, the various methods of drilling, blasting, mucking and timbering are treated in the same analytical manner and the discussion is so exhaustive and complete within the limits of the class of tunnels to which the authors confine it as to be of undoubted value and interest to anyone interested in the practical side of tunneling, whether engineer or foreman.

There is a chapter on Safety, one on Costs, and a Bibliography. The latter is arranged for convenient reference under some 30 different headings such as for instance, Steam Power, Water Power, Tunneling Machines, Drilling Methods, Speed Records, etc., etc. There is an index at the end which is well arranged and seemingly quite complete.

Speaking generally, this book is a distinct and quite valuable acquisition to the literature of tunneling. There is nothing at all in English which the writer knows of which has attempted to cover the same field, and the authors are to be congratulated on having accomplished a difficult task so well.

They have, however, in their discussions of methods practically entirely ignored the field of railway tunnels, or any tunnels of larger cross-section than that in which the entire excavation is made at one operation, and practically nothing is said regarding methods of tunneling in soft ground except in the chapter on timbering.

*Consulting Engineer, [illegible], New York City.

and this is rather brief and like the rest confined only to tunnels of small cross-section.

So far as rock tunnels of large cross-section are concerned, of course, the methods described are quite as applicable to the heading work as they are to the class of small tunnels discussed, but there are many factors controlling the operation of the excavation of rock tunnels of large cross-section which need the same kind of analysis as has been here given to the small tunnels; such, for instance, as the economies of shaft sinking, the relation of the heading to the enlargement, the questions of top and bottom headings, the use of steam shovels for mucking, the clearance of the heading operations from those of the enlargement, etc., etc.

The Bibliography occupies some sixty pages, but it is doubtful if its value is as great as that of the rest of the book, as it is far from complete. In the first section, for instance, covering "Tunnel Description," there is no reference to the two volumes of the Transactions of the American Society of Civil Engineers, describing the New York Tunnels of the Pennsylvania Railroad, or to many other articles of seemingly equal importance to those quoted, although there are included references to such works as the "The Blackwell Tunnel in London and the Tunnels of the Hudson & Manhattan Company in New York," both subaqueous, shield driven, and therefore, apparently outside of the scope of the book. It is true that there is a note to the effect that this is a "selected" bibliography, but the value of anything of this kind is largely in its completeness. Many references are duplicated under the various headings and for future consideration it might be suggested that the bibliography be made complete in one section with an index to the various subjects covered.

How to Operate Sewage Works: A German View

REVIEWED BY EMIL KUICHLING*

ABWASSERREINIGUNGSANLAGEN IHRE LEISTUNGEN UND IHRE KONTROLLE VOM CHEMISCH-PRAKTISCHEN STANDPUNKT—Von Prof. Dr. K. Thumm, Abteilungsvorsteher an der Königl. Landesanstalt für Wasserhygiene in Berlin-Dahlem. Berlin: August Hirschwald. Paper, 6x9 in.; pp. 92. 2.80 Marks.

This monograph deals mainly with the scientific management of sewage-disposal works, and emphasizes the obligation to conserve the purity of the outfall waters into which the effluent is discharged. It frequently happens that well designed works fail to be efficient when skilled supervision is neglected, and the operation is carried on chiefly with the view of avoiding complaints about offensive odors. In such cases, a serious pollution of the outfall is often the natural consequence, and hence a careful manager must give due attention to both the plant and the outfall.

The subjects considered embrace the physical and chemical analyses of water, sewage and effluents and the operation of disposal works of every description, embracing screens, sedimentation tanks, chemical treatment, septic tanks, natural and artificial filters or biological purification processes, final purification of the effluent in fish-ponds, treatment of sludge, and the scientific supervision of the outfall; and in conclusion, a brief review of the preceding chapters is given with some general remarks about the treatment of industrial wastes. Numerous analytical data and descriptions of methods of examination are presented, together with the results attained by the various modes of treating sewage of different strength or quality.

The book is well written and contains much valuable information in condensed form. Its keynote is that the secret of a successful result in operating sewage-disposal works is careful management, guided by scientific knowledge and practical experience in securing the utmost efficiency of every available appliance.

Multiplication by Addition, Subtraction and Division

REVIEWED BY ROSSITER R. POTTER*

COX'S COMMERCIAL CALCULATOR; A Novel and Easy Method of Multiplication, One Formula for all Calculations, Range of Results from a Single Unit to Over Ten Billions, Automatic Index to Tables—By Edward L. Cox, Southport, Lancashire, England. New York: Funk & Wagnalls Co., and the Remington Typewriter Co. Linen; 7x11 in.; pp. 101. $10.

The tables of figures making up this book may be used to find the product of any two whole numbers whose sum does not exceed 202,000. In other words, they may be used for multiplying together any two numbers having up to five digits apiece and they cover besides a limited range of six-place multiplications. The products are not obtained directly from the tables, but indirectly from "key numbers" obtained by a simple manipulation of the multiplier and multiplicand. The lesser of the two numbers to be multiplied is first subtracted from the greater. Dividing the difference by two gives the first key number.

$$\frac{A - B}{2} = \textit{first key number} \qquad (1)$$

The second key number is then obtained by adding the smaller of the numbers to be multiplied to the first key number.

$$\frac{A - B}{2} + B = \textit{second key number} \qquad (2)$$

The number in the tables corresponding to the first key number is then subtracted from that for the second key number and the resulting difference is the desired product.

The explanatory text and instructions occupying the first three pages do not tell the secret of the book's operation. A moment's consideration, however, of the algebraic form of the key numbers, as given above, shows that the book is simply a table of squares.

$$\left(\frac{A - B}{2} + B\right)^2 - \left(\frac{A - B}{2}\right)^2 = AB \qquad (3)$$

The difference of the squares of the key numbers gives the product of the principals. Besides the explanatory text telling how to use the book for multiplying, it differs from ordinary tables of squares in being ingeniously arranged to be self-indexing. The proper page can be turned to at once and the desired number very quickly located. It gives the squares of all numbers up to 100,999.

The chief use of these tables as a means for multiplying is with numbers of five and six places. Even here it is necessary to actually write down more figures than in long-hand multiplication and the time required is about the same. For smaller numbers than five places,

*Assistant Manager and Production Engineer, Blood Bros Machine Co., Kalamazoo, Mich

the long-hand method is quicker, though perhaps more liable to error. The Cox method requires less mental exertion and not such close attention, since the chief operations involved are addition and subtraction. In this respect the Cox tables are comparable to a table of logarithms. They are about equal in scope to a table of six-place logs, with the advantage that the products obtained are exact to the last digit without the need of interpolation.

NEW PUBLICATIONS

[So far as possible the name of each publisher of books or pamphlets listed in these columns is given in each entry. If the book or pamphlet is for sale and the price is known by the editor the price is stated in each entry. Where no price is given it does not necessarily follow that the book or pamphlet can be obtained without cost. Many, but not all, of the pamphlets, however, can be secured without cost, at least by inclosing postage. Persons who are in doubt as to the means to be pursued to obtain copies of the publications listed in these columns should apply for information to the stated publisher, or in case of books or papers privately printed, then to the author or other person indicated in the notice.]

The Spokane River and Hangman Creek Viaduct of the O. W. R. R. & N. Co.

By J. O. Baar*

Where the Oregon Washington R.R. & Navigation Co. gains entrance to the City of Spokane, Wash., over its new line from the west, it crosses the valleys of the Spokane River and Hangman Creek on a single-track steel viaduct 3003 ft. long and 187 ft. high above low water. At the site of the bridge, the Hangman or Latah Creek is nearing the end of its course, and is separated from the Spokane River, which it parallels at that point, by a low ridge only a few hundred feet wide. The bridge traverses the valleys at right angles and at the narrowest point.

*Civil Engineer, 720 Northwestern Bank Bldg., Portland. Ore.

Description of the Viaduct

Design—The alignment of the bridge is tangent for 2700 ft., terminating in a spiraled 5° curve on the west end. The grade is 0.6% [illegible], downward to the east.

Several preliminary studies were made in connection with this structure. The design finally decided upon contains two spans of 105 ft., 17 of 80 ft., four of 70 ft., one of 60 ft., three of 50 ft., 20 of 40 ft., one of 45 ft. and three of 35 ft., all deck plate-girder spans. The main portion consists of 80-ft. spans between 40-ft. towers, with two 105-ft. river spans.

The design of the superstructure was based on the O. W. R.R. & N. standard wheel-loading, which practically corresponds to Cooper's E55. The specifications used allowed a stress of 8000 $\left(1+\frac{min.}{max.}\right)$, reduced by [illegible] for compression. A rather low bearing value on concrete masonry was used, 250 lb. per sq.in. This necessitated the use of large cast-steel column bases, those for the river piers being 4 ft. 2 in. square.

The tower columns are of built-up channel section, having 18-in. webs, 4x4- and 6x6-in. angles and 22-in. cover plates. The maximum cross-section (at bents 11 and 12) is 67 sq.in. The struts are made up of 12-in. channels placed back to back and latticed, those over 27 ft. in length being supported in the center by vertical hangers riveted to the gusset-plates at the intersection of the diagonal braces in the panel above. Two 4x3- to 5x4-in. angles with batten plates were used for diagonal bracing.

The girders are spaced 8 ft. c. to c. and are of uniform depth of 8 ft. 9 in. throughout the entire bridge, except in the 105-ft. river spans and the 50-ft. span between, where they are spaced 10 ft. center to center, with the long girders 9 ft. 8 in. deep. They were designed with clear [illegible] flanges built up of 6x6-in. angles and 8-in. side plates, allowing all ties to be of the same depth and without daps for cover plates at river bents.

All 70-ft. and 80-ft. girders were designed with simple sliding expansion at the down-grade end. The 105-ft. girders, however, have rocker bearings and segmental expansion rollers [illegible] between [illegible] surfaces.

The design of the masonry foundations was based on a safe bearing value of the soil of 4 tons per sq.ft. For the dry-land foundations, pedestals 3 to 6 ft. square on top were used, ranging in height from 6 to 31 ft., with the sides battered from 1 : 12 to $1\frac{1}{2}$: 12, the batter varying inversely as the height. Two anchor bolts of 2 in. to $2\frac{1}{4}$ in. diameter, ranging in length from [illegible] ft. to 11 ft., and connected at the lower end by a steel plate, were embedded in the concrete at a depth where the weight of the concrete above the plate would resist the uplift. The pedestals are of 1 : 3 : 5 concrete, resting on footings of 1 : 3 : 6 mixture.

Open-Caisson Piers

The depth of excavation for the dry-land work varied from 5 ft. to 22 ft., for the Spokane River piers inside the high-water line from 9 to 22 ft., and for the Hangman Creek piers 14 to 21 ft. All dry excavation was done by hand, a force of from 10 to 25 men keeping [illegible] well in advance of the concreting crew.

The Spokane River piers were constructed by the open-caisson process. These piers are diamond shaped 6 ft. wide on top and 12 ft. from point to point, with the sides battered $1\frac{1}{4}$: 12. They rest on from 22 to 26 timber piles.

The formation quite uniformly encountered was a deep bed of well packed coarse gravel and sand with embedded boulders, overlaid with from 2 to 4 ft. of sandy soil. Occasionally, pockets of volcanic ash were met with. Test-borings carried to considerable depth in the river beds revealed no change in the general formation.

For the river work, a temporary pile trestle was first built on the center-line of the bridge, with the deck at an elevation of 8 ft. above low water, which was sufficiently high to take care of such floods as might reasonably be expected during the period of construction. Extensions of this trestle at right angles were built at the center of the river towers, so that all piers could be reached. The caissons, averaging 22 ft. in depth, with inside dimensions 2 ft. larger all around than the footings of the piers, were built up of 3x10-in. plank laid on the 10-in. face and spiked together with 60d. nails. Sections 6 ft. high were put together on the trestle, a V-shaped cutting edge of timber drift-bolted to the bottom, and towed out to their location, where they were anchored to guy piles, previously driven. The caissons were then completed in the river and weighted down with rails distributed in such a manner that any part of the interior could be reached with an excavating bucket.

The excavation was done with a clamshell bucket of 1 cu.yd. capacity, operated from a stiffleg [illegible] derrick placed on the trestle at the intersection of the wings. The excavated material was deposited around the caissons. In excavating, the cutting edge was first evenly undermined to insure a uniform settling of the caisson. Occasionally, a caisson would list rapidly to one side, then the opposite side would be additionally counter-weighted and undermined until it righted itself again. After the excavation was completed, 4x8-in. t. & g. sheetpiling was driven snugly against the outside of the caisson, from leads suspended from the derrick. Where the sheetpiling did not drive up tight, the intervening space was filled with [illegible], rammed to shut out the water.

The foundation piles, 22 to 26 under each pier, were driven next, with a 2200-lb. drop-hammer piledriver equipped with 20-ft. leads and 15-ft. extension leads, and 7x10-in. hoisting engine using a [illegible]-in. steel cable for the hammer line and a [illegible]-in. steel cable for the pile line. The piles were driven to refusal at an average penetration of 18 ft.

Before attempting to pump the caissons dry, the bottom was sealed with a 5-ft. layer of 1 : 3 : 5 concrete, deposited with a tremie, a 10-in. steel pipe slightly flared at the lower end and a [illegible] receiving funnel riveted to the upper end, operated from a scaffold set on the caisson. It was found that the best concrete resulted by starting with a dry batch and following it with semi-fluid concrete. The dry concrete would keep the water out of the tremie and the thin concrete would come out slowly and spread itself evenly.

Leakage Troubles—Much difficulty was encountered in pumping out the caissons. For this purpose, one 6-in. and one 4-in. centrifugal pump were installed. The many joints in the caissons, almost every one of them allowing leaks, led to so much water that both pumps working together never lowered the water more than 7 ft. To make the joints watertight, cedar shingles sharpened to

a thin edge were driven into the larger cracks of the pumped-out section, after which the water could be lowered a few feet farther, and the process repeated; afterwards, the small leaks were stopped with waste. The piles were then cut off 2 ft. above the concrete, and the remaining portion of the footings completed with 1 : 3 : 5 concrete.

For the construction of the Hangman Creek piers, it was not necessary to build a temporary trestle. At the time the work was commenced, the creek was practically dry. However, Hangman Creek is subject to severe and sudden floods, so it was decided to use caissons for the top of the forms and one or two lanterns in the space between the canvas and the concrete kept the frost out successfully. The cost of heating the aggregate, etc., was 12½c. per cu.yd. concrete.

Erecting the Superstructure

The steel for the superstructure, shipped from the East to Hooper, on the O. W. R.R. & N. Co.'s cutoff, about 83 miles southwest of Spokane, was brought to the site over the new line. The west approach of the bridge being an embankment over 3000 ft. long and an average of 20 ft. high, followed by a series of short and com-

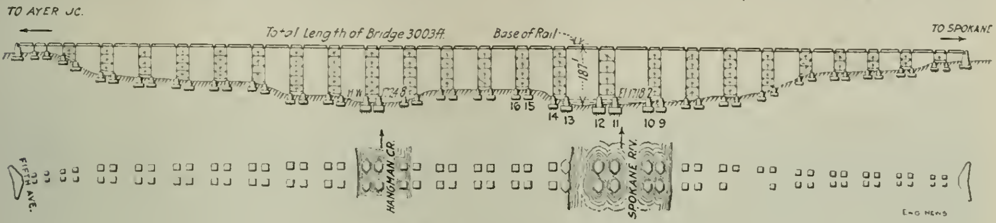

Fig. 4. Diagram of the O. W. R.R. & N. Co.'s Viaduct over Spokane River and Hangman Creek at Spokane, Wash.

six piers, similar to those employed on the Spokane River foundations. It was well that such provision had been made; the creek rose rapidly while excavating, but no damage was done to the foundations. The work of excavating was done by hand, using buckets operated from a small hoist to dispose of the muck. The foundation piles were driven and cut off before placing concrete, one 6-in. centrifugal pump keeping the pits dry.

The forms for piers and pedestals were built of 2x8-in. t. & g. fir and tamarack, with four 2x8-in. studs on the north and south faces and three 2x8-in. studs on the others. The two center studs on the north and south sides were spaced 6 in. center to center and cut off 2 ft. above the top of masonry. These were used to support a 4x8-in. plate, provided with two 2-in. or 2½-in. holes through which the anchor-bolts were hung. Around the anchor-bolts were placed tapered boxes made of half-inch lumber, 4 ft. long, 6 in. square at the upper end and 3 in. square at the lower end, the top flush with the top of the pier. Before concreting, the boxes were covered with grease, and upon completion of the pedestal they were removed, thus leaving sufficient space to correctly realign anchor-bolts which might have been displaced. It was found best to loosen the boxes about one hour after the last of the concrete was poured, and then no difficulty was experienced in removing them entirely when the forms were taken down. Occasionally, this would be neglected and the boxes were so tight that they had to be burned out.

Perhaps 60% of the concrete was placed in freezing weather, with temperatures as low as 18° below zero; then proper precautions had to be taken to insure satisfactory results. The sand and crushed rock were heated by turning steam into perforated wooden boxes 8 in. square and 20 ft. long, on top of which the aggregate was dumped to a depth of 3 ft. directly from the wagons. This proved sufficient at all times to keep the frost out of the material. The water was heated to a temperature of about 70° and the exhaust steam of the mixer engine was discharged into the drum. Canvas placed over the paratively high cuts and fills, the storage facilities were not the best. The steel was therefore distributed along the roadbed for a mile and a half west of the bridge. A blind siding in a borrowpit served to store and switch derrick cars and steel cars awaiting unloading. For unloading, two small self-propelling derrick cars, equipped with a two-drum, three-spool hoisting engine, 40-ft. timber boom hinged to a revolving center post in the A-frame, rigged for a capacity of 25 tons, were used. For the erection, a stiffleg A-frame derrick-car was specially designed. The body of the car, consisting of six 9x18-in. by 70-ft. timbers, cross-braced and so spaced that the width of the car was made 11 ft., was carried on one eight-wheeled truck in front and two sets of wheels placed 6 ft. and 20 ft. respectively, from the rear end of the car. The derrick was run on four rails spaced standard and 8-ft. gage. The A-frame, 50 ft. high, 5 ft. wide on top and 11 ft. at the base, was framed of two 12x14-in. batter posts and one 18x19-in. center post, cross-braced in the manner of a trestle bent. Two rear stifflegs of 14x14-in. by 80-ft. timbers extended from the top of A-frame to the rear of the car. The boom consisted of one 18x18-in. by 81-ft. Oregon fir timber, trussed on all four sides with a 4x18-in. plank. The fixed end was hinged to a bullwheel placed directly in front of the A-frame, a special engine operating the swing cable. Power was supplied by a double-drum, four-spool American hoisting engine. The drums carried ⅝-in. steel cable rove through six-sheave blocks on the mast and boom. From the spools were operated two runners or side lines running through single sheaves placed at the end of the boom, one on each side of the load line.

This car never left the bridge. The steel was brought to it by the small derrick cars and placed on outriggers consisting of 12x12 timbers 22 ft. long, put under the track and projecting 6 ft. beyond the ends of ties, braced by struts resting on the bottom flanges of the girders. As the erection progressed, these outriggers were moved ahead so that the main car never had to back up more than 500 ft. to get the material.

Before placing the cast column bases, the piers were carefully gone over and, where the shrinkage of the concrete was less than provided for, bush-hammered to the proper elevations. The work of erection was carried on from the west end only. After the bents reached a certain height, it was found most economical to bolt up two column sections in the yard, thereby lessening the work in the field. The columns and struts were placed with the head wire, the transverse and longitudinal beams with the side lines or runners. Where the ground was suited, the top section would be completely assembled on the ground and then raised. Temporary erecting struts were used to stay the bents forming the east supports of tower spans. The longitudinal or tower bracing was filled in as the erection of the farther bent progressed. [...] of bent 13. The bent was held in a position slightly inclined from the horizontal by two lines fastened to bent 13 at the second strut from the top (see Fig. 2). The three lower column sections of the bent to be erected were completely riveted in the yard and the cast bases bolted on. A temporary timber blocking was put around the anchor-bolts in the piers, and the columns were so placed thereon that when the bent was vertical, the anchor-bolts would match the corresponding holes in the column bases.

These preparations being completed, the columns were moved to the outriggers. In placing these long members, the movement of the lower end had to be guided by one of the small derrick-cars until the column was in a ver- [illegible]

Fig. 5. The Completed Spokane-Hangman Viaduct

ing was filled in as the erection of the farther bent progressed.

Erecting the [illegible]

The most interesting feature was the erection of bents 13 and 12, forming the east supports for the [illegible] girders. With the equipment on hand, two methods were open: (1) to erect the bent vertical, necessitating the [illegible] of every member a distance of 90 ft., or (2) to erect it in an inclined position on a temporary support. The latter method was employed.

For this purpose, a temporary timber bent 42 ft. high, consisting of four 12x12 posts and caps braced with 8x12 timbers, was framed. The center-to-center distance of the posts at one end corresponded with the column distance of the columns of bent 12 at a point just below the fourth transverse strut, and on the other end with the column spacing of bent 13 at the third transverse strut. One end of the bent was lashed to the columns

that position, after which it had to be anchored to the pier and was finally placed with the upper end resting on the temporary bent. After both columns were properly aligned, the transverse struts were connected up, the bottom section was assembled on the ground and [illegible] into place.

[illegible] the Bent

With the bent in the inclined position, a double-chain was swung around the columns immediately above the third transverse strut, and to this one of a set of 12-in. [illegible] blocks was attached, the other block being made fast to a guy line carried out to a post on the east side of the river. The line from through the set of blocks [illegible] was carried upward and over the top of the bent and thence to a snatch-block as well as the double-engine. In order to keep the line from fouling the top strut, the [illegible] was passed through a snatch-block made fast to the end of one of the runners. This block

is seen in the illustration immediately back of the diamond block at the end of the boom. The second runner line passed from its sheave through a snatchblock made fast to the top transverse strut, thence it led and was made fast to a pier on the east bank of the river. In order to prevent the bent from falling forward as it assumed a vertical position, should anything happen to the load line, two snublines were attached to the columns of the bent being erected, leading to bent 13 and made fast thereto.

Power was applied simultaneously to the load line, the line leading from the set of blocks guyed to the east side of the river and to the second runner line described above. The bent then assumed a vertical position, resting on blocking placed around the anchor-bolts, as previously described. With the bent in this position, a slight strain was taken on all the lines, holding the bent as rigidly as possible, while two 35-ton Norton jacks were placed under the lower transverse strut immediately adjacent to the columns, and the entire bent was lifted sufficiently to release the blocking. The blocking was then removed and the bent uniformly lowered over the anchor-bolts. The outhaul line was snubbed around the top transverse strut, and all other lines attached to the derrick car let go.

In the meantime, the 105-ft. girders were placed on the outriggers by the small derrick cars working boom to boom. The main car then backed up, and, picking up one of the girders, moved forward and landed it in position, after which it was bolted down. The other girder was then placed and the braces filled in.

Bent 10, the east support of the other 105-ft. span, was erected in a similar manner.

The riveting was done by compressed air, a plant of 250 cu.ft. per min. capacity being installed for that purpose at the west end of the bridge, from which a pipe line was extended to the front on the deck of the structure. From six to eight riveting crews riveted the steel as fast as it was erected. All field rivets were given one coat of black graphite paint.

Engineering

No difficult features presented themselves in establishing the center line. After the line was definitely located, substantial hubs were driven at intervals not exceeding 100 ft., projecting far enough above the ground surface to allow the tape to be suspended between points. In these, wire brads were set to serve as chaining points, the tops of hubs being trimmed to an apex at the brad. These hubs were numbered in succession from the east end, and the distance between them measured with a standard tested tape, graduated to feet and hundredths. Readings were taken to the nearest thousandth of a foot, the pull being measured with spring balances and the temperature read to the nearest half degree. Levels were then run carefully over the hubs, and, with the measured distance and the difference of elevation between points, the horizontal distance was computed, and checked in the field by horizontal chaining. At the center line of each bent, a substantial hub was driven 3 ft. into the ground, with the top flush with the surface. At every fourth bent, a concrete hub was placed. The Spokane River was triangulated first, and after the temporary trestle was built, the distance was checked by actual chaining. Great care was taken in setting the anchor-bolts, with very gratifying results throughout. After the bridge was completed, its length was measured on the deck, and checking the original chaining within 0.02 ft.

The construction of the substructure for this bridge was commenced in August, 1911, and rushed to completion by March, 1912. The quantities involved were: 8250 cu.yd. excavation, 14,400 lin.ft. piling, 1110 cu.yd. 1 : 3 : 6 concrete, 4155 cu.yd. 1 : 3 : 5 concrete, and 285 cu.yd. 1 : 2 : 4 concrete. For the superstructure, 3822 tons of structural steel were used.

A change in the plans for delivery of the steel caused the erection of the superstructure to be delayed until June, 1913. The bridge was completed in November, 1913, and opened for traffic the same month.

Chaugren, Boynton & Co., of Spokane, had the contract for the substructure. The superstructure was fabricated by the American Bridge Co. and erected by the Kelly-Atkinson Co., of Chicago. G. Schennewerk and E. Baggs acted as superintendents. The writer was engineer-in-charge for the Oregon-Washington R.R. & Navigation Co.

Permeability Tests on Gravel Concrete are being made at the University of Wisconsin. A progress report by Prof. Morton O. Withey, read before the Western Society of Engineers, Sept. 14, 1914, gave the following summary of the tests so far made.

1. None of the concretes tested were absolutely watertight if we consider continuous flow into the specimen as proof of permeability, but the majority of the mixes [varying from 1:1 to 1:3:6] were so impervious that no visible evidence of flow appeared. For most purposes such mixes can be considered water-tight.

2. The visibility of dampness on the bottom of the specimens increased with the humidity of the air and the nonhomogeneity of the concrete. The minimum rate of flow for which leakage was indicated was 0.00011 gal. per sq.ft. per hr.

3. In tests of nearly all of the properly made mixes of 1:7 proportions, or richer, the rate of flow for a 50-hr. period was less than 0.0001 gal. per sq.ft. per hr. under a pressure of 40 lb. per sq.in.

4. Through increasing the fineness of the cement a reduction in the rate of flow and a considerable increase in the strength of a 1:9 mix were secured.

5. By grading the sand and gravel in accordance with Fuller's curve it was possible to obtain practically watertight concrete of 1:9 proportions under pressures less than 40 lb. per sq.in. To secure such results, however, requires great care and careful supervision in mixing, in determining the proper consistency, in placing, and in curing the concrete.

6. In the proportioning of such materials as these, volumetric analysis coupled with a determination of the density and air voids yields very valuable information concerning the best proportions of sand and gravel for a given proportion of cement. If proportions must be selected arbitrarily a 1:1½:3 mix, by volume, is very impervious.

7. The use of the proper amount of water necessary to produce a medium or mushy consistency is one of the most important conditions in securing impervious concrete, especially when lean mixtures are used. Dry mixtures cannot be sufficiently compacted in the molds and are more difficult to cure properly than the mushy mixtures. Although the use of a wet consistency does not materially affect the imperviousness of very rich mixes, such as 1:1½:3, it greatly increases the flow through a lean mix.

8. For lean mixes made from damp sand it seems advisable to mix longer than is now common practice. These tests would indicate that for a mixer running at 30 r.p.m., a period of one and one-half to two minutes is required to secure thorough mixing of a 1:9 concrete. For a rich 1:1½:3 mix a one-minute period appears to be sufficient. The method of mixing in which water is first admitted to the mixer is to be condemned. A preliminary period of dry mixing lasting from 15 to 30 sec. seems desirable.

9. No stage or process in the making of impervious concrete is of more importance than curing. The results of these tests clearly demonstrate that premature drying destroys the imperviousness of 1:9 mixes, seriously impairs that of the 1:2:4 mixes and somewhat diminishes that of the 1:1½:3 mixes. For thin sections, not over six or eight inches thick, the curing conditions should be such that a lean concrete will be kept damp for a period of one month and a rich concrete for at least two weeks. Even after a month of proper curing, complete desiccation of a lean mix composed of these materials produces an increase in permeability, but the effect on a rich mix is not marked.

10. In these tests the imperviousness of the concrete increased rapidly with the age of the specimens for the first month; thereafter the change was not marked.

11. From the tests thus far made it seems probable that the permeability of lean concrete in a direction normal to the pouring is greater than in the direction of pouring.

Pipe-Laying Methods on the Narrows Siphon of the Catskill Aqueduct, New York City

The general features of the Narrows siphon of the Catskill Aqueduct were described and illustrated in Engineering News of Apr. 30, 1914, pp. 916-918. The present article and illustrations give some additional points, developed in the construction work, which are taken from a recent description of the project prepared by the engineers of the Board of Water Supply of the City of New York.*

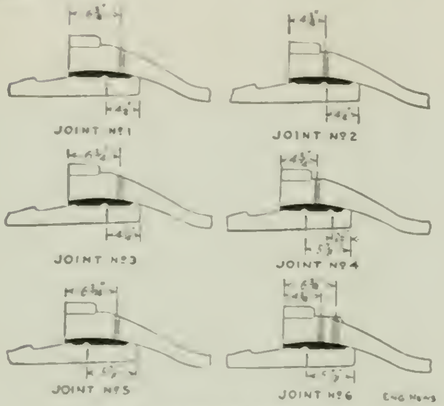

Fig. 1. Evolution of Joint

The Narrows pipe line, which is being constructed to supply Staten Island with water from the Catskill Aqueduct, will consist of a 36-in. cast-iron flexible-jointed submarine pipe, about 10,000 ft. long, containing in all approximately 4000 tons of pipe.

Before deciding on this type of construction, many schemes were investigated. A pressure tunnel, such as has been used on the main line of the Catskill Aqueduct, was not well adapted to the conditions on account of the comparatively small quantity of water to be delivered, the length of the crossing, the great depth of the underlying rock, the difficulty of making additional borings, and the long time required for exploration and construction. The estimated cost of construction of a [illegible] tunnel was very much greater than for this pipe line.

The crossing has many of the usual difficulties encountered in laying submarine pipe, and in an exaggerated degree. The Narrows is the main entrance to New York harbor from the ocean; through the channels pass the largest steamships afloat and very many craft of all kinds, making it one of the busiest channels in the world.

The pipe line will cross the anchorage grounds for [illegible] and lines of [illegible]. Across the anchorage ground [illegible] about 50 ft., [illegible] to about [illegible] ft. below [illegible] for a length of nearly [illegible] ft. is required.

Government regulations require that no refill shall be placed above [illegible] ft. below mean low water, and protection of the pipe requires about 3 ft. of refill, so that the bottom of the pipe must be at least 56 ft. below mean low water. This great depth made it advisable to do as much of the work on the surface as possible, and therefore the continuous method of laying pipe by means of a cradle was preferred to any method of lowering the pipe in sections and joining them together on the bottom.

The modified Ward joint, known as the Doane joint, was selected as the highest development of the flexible joint to date. Experiments were made with a view of adapting it to the excessively rigorous conditions met in the Narrows. This joint is essentially a ball-and-socket joint, the socket being the bell of one pipe, and the ball the lead-covered spigot of the adjoining pipe.

On account of the shrinkage of the lead, all poured joints leaked excessively until calked at the face. The effect of the calking penetrates only ¾ in. into the lead, and as the pipe is deflected while laying at least 5°, corresponding to a horizontal movement of 2 in. along the line of the joint, the effect of any face calking done on the scow would be destroyed while laying. To obtain a tight joint, calking would therefore have to be done by divers after the pipe had reached the bottom. This would be extremely laborious and expensive on account of the great depth and strong tidal currents which limit the hours divers can work.

Experiments were conducted prior to letting the contract with a view to developing a joint which would not require calking under water. Various alloys of lead with tin and antimony were tried with a view to developing

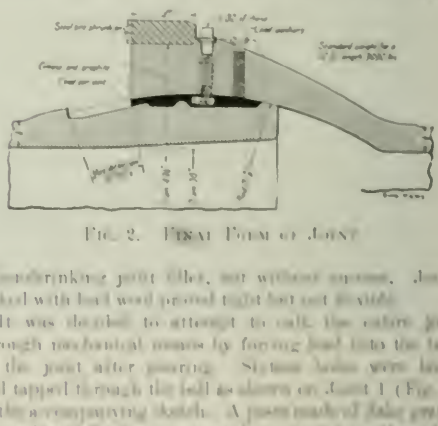

Fig. 2. Final Form of Joint

a nonshrinking joint filler, but without success. Joints calked with lead wool proved tight but not flexible.

It was decided to attempt to calk the entire joint through mechanical means by forcing lead into the back of the joint after pouring. Sixteen holes were bored and tapped through the bell as shown on Joint 1 (Fig. 1) in the accompanying sketch. A [illegible] flake graphite and anti-friction compound was put into these [illegible] holes and forced into the joint by screwing in [illegible] or pit screws. Lead plugs ½ in. in diameter and 1 in. long were then screwed down, about seven pellets per hole being used, amounting to nine pounds of lead for the whole joint.

The joint proved to be tight and flexible under ordinary conditions and the promise of ultimate success was sufficient to proceed with the letting of the contract. The contract was awarded May 7, 1914, to the Merritt & Chapman Derrick & Wrecking Co., at an estimated total cost of nearly $1,000,000.

There were still extraordinary conditions to be met and many details to be worked out. Accordingly, through the cooperation of the contractor, experiments were resumed after the letting.

In addition to tightness and flexibility it was desired

*From an account [illegible] prepared [illegible] the work by the [illegible] of the City of New York and [illegible]

Fig. 3. Type of Joint Used on Narrows Subaqueous Pipe-Line

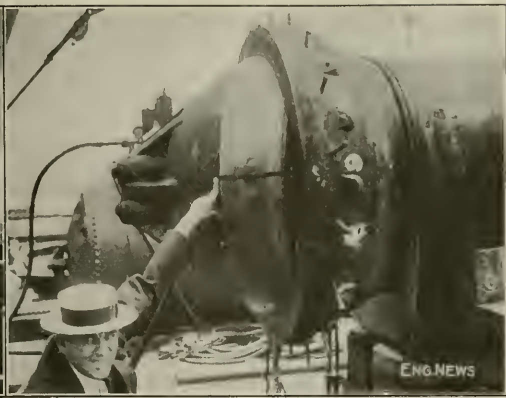

Fig. 4. Bulkhead for Closing Pipe to Make Pressure Tests of Joints

to get a joint which would have the greatest possible strength against longitudinal pull. The ordinary joint, even though uncalked, becomes tight when subjected to a longitudinal strain, but when the strain is released the leakage is worse than before. On account of the length of the Narrows siphon, sag could not be relied upon to tighten the joints, and in addition the stress and movements due to changes of temperature had to be considered.

It was with a view to increasing the longitudinal strength that the gib-screw hole was moved to the position shown in Joint 2 (Fig. 1), with the idea of concentrating the lead at the great diameter of the bell. This was not successful as the lead tended to flow freely out of the face of the joint instead of filling it up.

Joint No. 3 (Fig. 1) was a repetition of the preliminary experiments on Joint 1, using a larger quantity of lead in order to gain strength. Though this joint was satisfactory in many respects it still failed to give the desired longitudinal strength, because after a certain amount of lead had been forced in, further injection drove the spigot out faster than it filled up the space in the joint.

Accordingly Joint 4 (Fig. 1) was tried, which proved to be very tight and to have a great deal of longitudinal strength; but is was not flexible, for it tended to

Fig. 5. Pipe-Laying Cradle Used on the Narrows Siphon, Catskill Aqueduct, New York City

ing, instead of the grease. Joint 5 (Fig. 10) was then tried; it proved flexible and strong longitudinally, but showed a slight tendency to leak between the spigot and the lead. Finally the second set of gib-screw holes were added, as in Joint 6 (Fig. 11); this joint proved a complete success and is the one being used.

The procedure of pipe jointing on the deck of the scow is as follows. The inside of the bell is coated

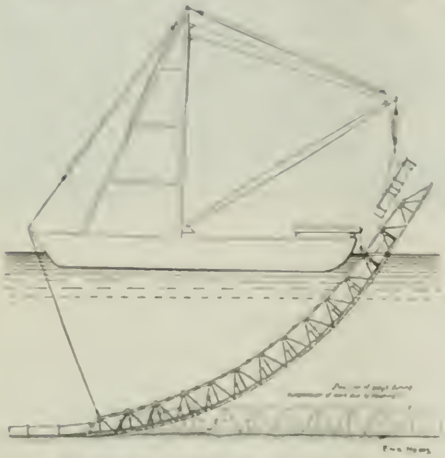

Fig. 6. Detail of Pipe-Laying Cradle

with graphite. The spigot of the next pipe is inserted and properly centered and the joint poured, using about 200 lb. of lead. Lead pellets 5/8 in. in diameter by 1¾ in. long are forced in by compressed air, three each in the [illegible] holes, three each in the front holes, and then one each in the back holes, using from 20 to 22 lb. of lead in all.

A mixture of grease with about 10% graphite is forced in each hole, and the holes are plugged with tap bolts and lead washers. The joint is deflected 5° and tested under a hydrostatic pressure of 100 lb. per sq. in. before launching from the scow, as described in the specifications (reprinted in the previous article above referred to).

The pipe-laying scow measures 40 ft. by 125 ft. It is held in position by 10 anchors. It carries the 20-ton derrick which is used for handling pipe and for auxiliary operating. At the beginning of the work it supported the pipe-laying cradle or skidway. The latter is now carried by cables running over a framework in the front of the scow. The cradle, or skidway, is made of structural steel and resembles a through truss, curved in the vertical plane. It is 100 ft. long, 8 ft. wide and 10 ft. deep and weighs nearly 60 tons. The pipe is held in place on the skidway by chain stops.

As soon as a joint has been completed and passed the derrick or scow moves ahead one length and the pipe at the lower end slips off to the bottom of the dredged trench. The skidway is then ready to receive another length of pipe at the top.

The work described is being done by the Board of Water Supply, of which J. Waldo Smith is Chief Engineer; Alfred D. Flinn, Deputy Chief Engineer; Thaddeus Merriman, Department Engineer; and Thomas H. Wiggin, Senior Designing Engineer. The work is under the city department, of which Walter E. Spear is Department Engineer; John P. Hogan, Division Engineer; James F. Murphy, Section Engineer, and E. P. Hopson, Section Engineer, in charge of Narrows siphon laying. W. L. Chapman is Secretary of the Merritt-Chapman Derrick & Wrecking Co., in charge of the Narrows siphon work for the contractor, for whom Ralph Chapman is Mechanical Engineer.

Wheel Pit and Elevator for Coach-Repair Yard; Michigan Central R.R.

The convenient handling of wheels and axles is one of the essentials in the design of a coach-repair yard, and the removal of wheels of passenger cars in the new coach yard of the Michigan Central R.R., at Detroit, Mich., is effected by means of a wheel pit and two elevators. Fig. 1 shows the deck framing of the pit, and Fig. 2 shows the elevator construction.

The pit is about 36x58 ft., and 7½ ft. deep, with a deck framing of I-beams 18 in. apart, arranged in two

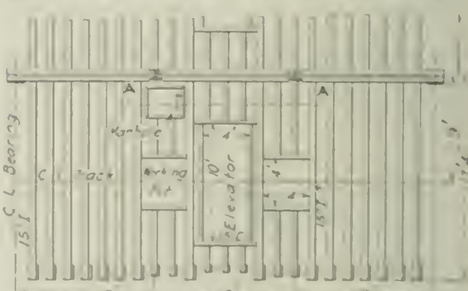

Fig. 1. Plan of Track Deck of Wheel Pit in the Coach Yard of the Michigan Central R.R. at Detroit, Mich.

spans. Their outer ends rest on bearing plates on the concrete walls and their inner ends are framed against a girder supported on columns and the side walls. In each span is an elevator opening 10x4 ft., closed by a repair track, and the elevator platform has a section of track about 4 ft. long, which forms a part of the repair track when raised and part of the wheel track in the pit when lowered. The elevators are operated by pneumatic cylinders, as shown in Fig. 2. Compressed air is taken from the pipes of the air-cleaning system in the coach yard, being supplied from compressors located in the basement of the station building.

At each side and end of the elevator opening is a pit about 4 ft. square. The floors of these pits are suspended about 4 ft. below the track and form platforms for the men working under the car, while they are high enough to allow wheels on the pit track to pass under them. These shallow working pits are covered by movable deck sections when not in use, as shown in Fig. 2. There is also a manhole opening about 36x30 in., having a hinged cover with segmental guides. This gives access to an iron ladder.

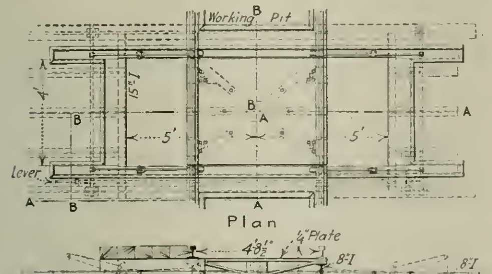

FIG. 2. SECTION OF WHEEL PIT AND ELEVATOR

The operation will be understood from the plan, Fig. 3. The team-track yard has a general elevation about 4 ft. lower than the repair yard. The wheel-loading track leads out from this yard, so that the floor of a flat-car in the wheel dock is just about level with the tracks in the repair yard, enabling wheels to be loaded or unloaded directly onto the track lying across the end of the repair tracks. Thence the wheels are placed in the storage yard, or if one of the repair tracks is empty they may be rolled directly to the elevator and taken down into the wheel pit under the repair tracks. A capacity of about four pairs of wheels is provided on either side of the elevator on this low-level track. New wheels are stored on one side and the other side is reserved for the removed wheels.

Coaches on the repair track are placed with the wheels to be removed directly on the elevator, so that they can be lowered as soon as released from the boxes. The elevator takes the wheels down, and they are rolled off and the new wheels rolled on. The elevator then ascends, bringing the axles with their journals in the bearings. When the repair track is again clear, the removed wheels are brought up on the elevator and rolled away into the storage yard. The principle of this wheel pit was taken from one in use in the Mott Haven yard of the New York Central R.R. At that yard, however, the wheels are stored on the lower level, to which they are brought by

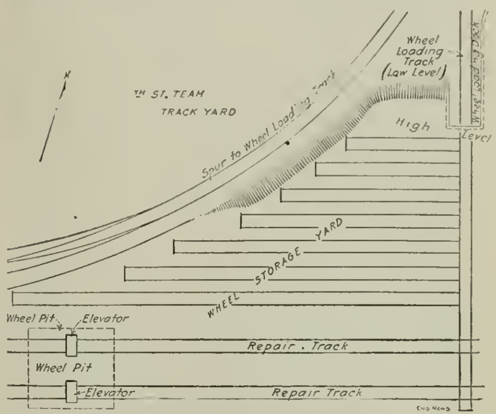

FIG. 3. PLAN OF WHEEL-STORAGE TRACKS AND COACH-REPAIR TRACKS WITH WHEEL PIT

an inclined plane, and are taken in and out from the side of the pit instead of being taken up and down on the elevators, the latter being reserved exclusively for removing and replacing the wheels under the cars.

The Export Trade in Iron and Steel and the relative prospects of Great Britain and the United States in securing the trade heretofore held by iron and steel producers on the continent of Europe are discussed by London "Engineering" of Sept. 18. The world's total export trade in iron and steel is about 20,000,000 tons per annum, of which about half has been supplied by the European continental countries now at war; 6,000,000 tons by Germany alone. Were the war to end shortly, it is assumed that financial and other losses would prevent Germany and Belgium from playing a large figure in the iron and steel export trade for some years to come. At present the financial stringency the world over has cut down the demand for export iron and steel to very small proportions. It is assumed, however, that this condition will gradually disappear and that the normal demand for iron and steel and its products from non-manufacturing countries will be reëstablished. "Engineering" concedes that in the competition for this business the United States firms will have the great advantage over the British firms of surplus capacity able to turn out the material required. It estimates the total capacity of American steel producing concerns at 30,000,000 tons of steel ingots a year, and the normal demand in the United States at 20,000,000 tons, leaving a margin of 10,000,000 tons available for export trade. Great Britain, on the other hand, has little surplus capacity, and when its home demands and the export trade it holds are normal, it can provide only a small part of the necessities of the remainder of the world. As to the relative cheapness of production in the two countries, "Engineering" thinks that Great Britain now has the advantage. In the past fifteen years the cost of iron and steel-making in the United States has materially increased, due to increases in ore royalties, cost of mining, cost of coal and coke, and falling off in the quality of ore. It is now estimated that the cost of iron and steel production in the United States has increased in the neighborhood of \$6 per ton since 1899. No similar increase has taken place in England, and "Engineering" therefore believes that with the advantage the English iron and steel works have of location near tidewater, they can export at prices as low at least as their American competitors.

A Method for Constructing a Tunnel under the East River at New York City

By Emil Diebitsch*

The construction of the four tunnels for the Pennsylvania Railroad under the East River at New York City showed the uncertainty of progress by the shield method of tunneling in this location. Sometimes the heading was lost during a blowout and it required weeks of labor to recover it. At other times several headings had to be shut down in order to turn all available air into the headings under operation. At all times enormous volumes of air had to be pumped into the headings and finally portions of the river bed had to be covered with clay in order to make any progress at all possible.

Similar difficulties were encountered in building the present subway tunnels to Brooklyn and in both instances the cost of the work was very high.

The fundamental cause of most of these troubles is found in the difference in hydrostatic pressure at the bottom and the top of a tunnel heading. Air pressure sufficient to keep the floor of a tunnel dry will be enough greater than the hydrostatic head at the roof of the tunnel to allow the air to escape in great volume; and when the cover is not sufficiently heavy, may even blow a hole through the river bottom and by thus suddenly reducing the air pressure in the tunnel allow the water and sand to enter the tunnel, resulting in a "blow-out."

In practice this difference in pressure is kept as small as possible by keeping the air pressure in the tunnel about equal to the hydrostatic head at the middle of the tunnel section; but it is still greater than the hydrostatic pressure at the roof of the tunnel, and this difference in pressure is the chief cause of the delays and expense in building tunnels by the shield method.

In the shield method, then, the work of excavation and construction is carried forward in a vertical plane or heading under a condition of unbalanced pressures. In the method herein proposed the work is carried on in a horizontal plane under a condition of balanced pressures. For this reason this new method permits of building tunnels more expeditiously and economically and consequently also the tunnels can be built at easier grades and [illegible].

The method in general consists of building successive lengths of the tunnel under the protection of a large movable pneumatic caisson which rests on the river bottom and extends above the surface of the water like a dock or pier.

When a section of the tunnel has been completed, the caisson is moved forward along the line of the proposed tunnel, so that another section of tunnel immediately adjoining the finished section and connecting with it can be constructed. By repetition of this process the entire tunnel between terminal shafts can be built.

This caisson is really a large steel box with double walls enclosing ballast chambers and forming a working chamber closed over the top but open at the river bottom. Water is excluded from this working chamber by means of compressed air and access to it for men and materials is gained by means of shafts and air locks in the usual way.

*Consulting Engineer, [illegible]

The word caisson is used to designate this steel box but it should be noted that this structure differs in design and function from the caissons used for foundations of bridges and buildings. It does not form the bottom of the finished structure as ordinary caissons do but is used as a temporary protective covering placed over the portion of the tunnel under construction and is moved to a new position as soon as the tunnel section is completed.

This caisson rests on the river bottom above and at the edge of the excavation within which the tunnel is built. It therefore has no cutting edge but a broad base, giving ample bearing surface for stability and to prevent the caisson from sinking too deeply into the mud of the river bottom.

To facilitate the handling of the caisson, it is provided with ballast chambers which can be readily filled or emptied of water by means of valves and pumps. These ballast chambers must be large enough to contain sufficient weight to hold the caisson securely on the river bottom when the tunnel construction is proceeding. Enough of the ballast should be water for easy handling which, when pumped out of the chambers, will permit the caisson to float.

Reference to the accompanying drawings will show that the caisson under consideration has the following principal dimensions: Length 120 ft.; width 50 ft.; depth 62 ft. Length of working chamber 100 ft.; width 40 ft.; height 25 ft. The estimated weight without machinery or ballast is 2500 tons.

This structure is large enough and strong enough to form when resting on the river bottom, a pier to which scows, lighters, tow boats, etc., may be moored and on which materials and supplies may be landed. The main deck of the caisson will be equipped with derricks, hoisting engines, concrete mixers and such other machines and appliances as may be needed for expeditiously and economically handling the excavated materials from the working chamber to the scows and the structural materials such as sand, gravel, cement, steel and lumber from the lighters to the air locks.

The machinery deck, located about 12 ft. below the main deck, will contain boilers, air compressors, steam engines, electric generators, pumps and such other machinery as may be needed in constructing the tunnel or handling the caisson.

The walls of the working chamber are provided with interlocking tongued and grooved poling boards or [illegible] which resemble steel piling. These steel poles are shown in the drawing as constructed of steel I-beams with grooved timbers bolted on each side of the webs of the beams. These steel poles are used as vertical poling boards and are carried down a little in advance of the general excavation and serve to keep the air within the excavation from escaping too freely. They also support the banks of the trench within which the tunnel is built. It should be noted that each steel pole is attached to the wall of the working chamber by means of bent steel plates forming a groove within which the steel pole can readily be moved vertically up or down but which prevents lateral displacement of the steel pole.

Having constructed the caisson as above described with all necessary men and material locks, ballast chambers, etc., and equipped it with air compressors, boilers, pumps, dynamos and other necessary machinery, the procedure is as follows:

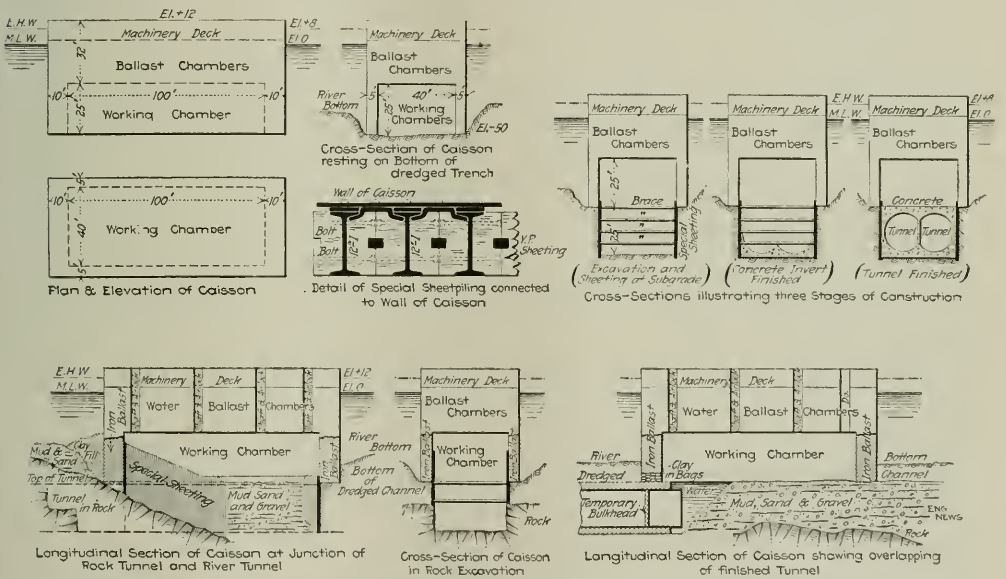
A trench is dredged along the line of the proposed tunnel, wide enough to hold the caisson when resting on the bottom of the channel and at least 45 feet below extreme low water, as the harbor regulations require the top of the tunnel to be below that depth.

The caisson is towed to a point selected for beginning work and sunk by flooding the ballast tanks until it rests on the bottom of the channel. Compressed air is forced into the working chamber until all of the water is excluded, some of the water being pumped out if deemed more expedient, and more ballast is added in order to hold the caisson in place.

Workmen now enter the working chamber and begin excavating, taking care to keep the sheeting below the excavation, and cross bracing the sheeting if necessary, as the excavation proceeds. When the bottom of the excavation is reached, concrete is placed to form the foundation and invert for the tunnel lining.

The tunnel can now be built as designed—whether of tion of the tunnel under the river, but provision must be made for connecting the river tunnels with the tunnels on the Manhattan and Brooklyn shores.

A study of the boring sheet made by the engineers of the Public Service Commission for the new subway tunnels from Whitehall St., Manhattan, to Montague St., Brooklyn, for which contracts were recently let, show that approaching the Manhattan shore the rock in the river apparently rises sufficiently above the top of the tunnel to permit of driving a tunnel in the rock in the ordinary way. In this case the caisson could be located near the point where the tunnel enters the rock from the sand and mud in the river and a heading could be started into the rock from the working chamber of the caisson. If the rock is of such a character as to require compressed air to keep the excavation dry, or compressed air and a shield, the air could be furnished from the plant on the caisson and the tunnel driven toward the shore, using the caisson as a shaft.



SKETCHES ILLUSTRATING A PROPOSED CAISSON METHOD FOR CONSTRUCTING SUBAQUEOUS TUNNELS

massive or reinforced concrete with waterproofing of fabric and pitch or asphalt or brick laid in asphalt. Should it be found desirable to surround the tunnel with a metal casing to act as waterproofing, this can be made of thin steel plates or of sheet copper.

When a section of the tunnel has been completed, the sheet piling must be drawn and secured to the walls of the working chamber after which the caisson is to be moved ahead.

The next step is to float the caisson by discharging ballast and to move it along the line until the rear end just overlaps the finished portion of the tunnel, thus allowing the end of the finished section to project into the working chamber. The caisson must now be sunk to the bottom of the channel in this position by flooding the ballast chambers, after which the work now proceeds as before.

These operations would serve for constructing the por-

If on the other hand the rock is solid and the tunnel can be driven without air, it might be advisable to bulkhead the tunnel after it has been well advanced into the rock and drive the rest of the tunnel under normal air pressure from a shaft on the Manhattan shore.

On the Brooklyn shore, where the tunnel enters earth and sand below mean high water, it may be advisable to use a shield. The shield could be set up in the working chamber of the caisson and operated with the plant on the caisson, using the caisson as a shaft for men and materials.

In considering the operations involved in this method of constructing tunnels, the following questions suggest themselves:

(1) The construction of a caisson of the magnitude indicated and the character of the stresses to be taken care of.

(2) The facility of handling a caisson of the dimen-

some [illegible] floating it, resting it [illegible], sinking it to the bottom of the river and subsequently raising it again. In this connection the force of the currents on the caisson must be considered.

(3) The stresses in the special sheathing which is used to carry the excavation below the bottom of caisson. The possibility of constructing this sheathing so that it will stand the strain and also be practically air-tight.

(4) Leakage of air from working chamber and trench.

(5) The advantages which this method of tunnel construction has under the existing conditions over the method of using compressed air and shields.

CONSTRUCTION OF CAISSON

In considering the first question, we will assume the following dimensions of the caisson: Length over all 120 ft., width 50 ft., depth from top to bottom 62 ft., length of working chamber, 100 ft., width 40 ft., height above bottom of caisson 25 ft.

When such a caisson is resting on the bottom of the river in 50 ft. of water, and a trench 25 ft. deep has been excavated below the edge of the caisson, the air pressure in the working chamber and trench necessary to keep water out of the bottom of the trench must be equal theoretically to the hydrostatic head of 75 ft. which is the distance from the surface of the water to the bottom of the trench. This hydrostatic head of 75 ft. is equal to a pressure of 32.55 lb. per sq.in. or 4687 lb. per sq.ft. This pressure produces a very heavy load on the walls and roof of the working chamber.

The stresses will not be discussed in detail here but they have been sufficiently developed to show that they can easily be taken care of with a steel structure weighing 3000 tons.

The working chamber is made 25 ft. high so that the sheet piles can be made in one piece and drawn up clear of the bottom of caisson when the latter is to be moved. The height of the working chamber and the fact that no cross braces are shown in the chamber increases the stresses in the walls but these increased stresses have been considered and the 3000-ton structure will take care of them.

The high working chamber offers several advantages in the economical handling of excavated materials, timbering, [illegible], etc., which do not, however, affect the principles of the method of construction and hence will not be discussed in detail here. These [illegible] the cost of the [illegible] steel due to [illegible] of beams in working chamber.

HANDLING CAISSON

Considering first the problem of handling the caisson in the water, we will assume that the caisson weighs 3000 tons and that the machinery placed upon it will weigh 200 tons. The caisson is 120 ft. long by 50 ft. wide and therefore displaces 6000 cu.ft. of water for every foot that it sinks into the water. This 6000 cu.ft. of water weighs 6000 × 62.5 lb. or 187.5 tons. Since the caisson [illegible] weighs 3200 tons it will sink 17 ft. [illegible] and by adding ballast can be sunk to any desired depth.

As it is proposed to seat the caisson on the bottom of a trench in 50 ft. of water, and [illegible] it [illegible] and sink it to the bottom again, it will be advisable to ballast with some heavy material such as pig iron so that the caisson will float at a depth of 45 ft. and can be sunk lower by adding water ballast. This will require 45×187.5 tons or 8437.5 tons less 3000 or 5437.5 tons of pig iron.

The space available for ballast is equal to the volume of the caisson below the machinery deck less the space occupied by the working chamber. The machinery deck is to be 12 ft. below the top deck and the volume of the caisson below that deck is equal to 120 × 50 × 50 = 300,000 cu.ft. From this deduct the volume of the working chamber 100 × 40 × 25 = 100,000 cu.ft. The space available for ballast is therefore 300,000 less 100,000 or 200,000 cu.ft. less the space occupied by structural members, shafts, etc.

Assuming that pig iron stacked as ballast will weigh 300 lb. per cu.ft., one ton will occupy 6.67 cu.ft. and 5437.5 tons will occupy 36,268 cu.ft. This leaves 200,000 less 36,268 or 163,732 cu.ft. of space for other ballast, when the caisson is floating at a depth of 45 ft.

This other ballast is required to sink the caisson to the bottom in fifty feet of water and hold it there, and as it has to be easily handled in order to sink or raise the caisson readily it will consist of water.

The maximum amount of ballast will be required when the trench under the caisson has been excavated to the subgrade of the tunnel, for there it will be necessary to have a pressure of air in the working chamber equal to a hydrostatic head of 75 ft.; this is 32.55 lb. per sq.in. or 4687 lb. per sq.ft. Under these conditions the uplift due to air will equal area of working chamber 100 × 40 or 4000 sq.ft. times 4687 lb. or 18,748,000 lb. or 9374 tons. To this must be added the uplift due to pressure of water on bearing area of caisson, the bottom being 50 ft. below the surface of the water and the bearing surface having an area of 2000 sq.ft.; the pressure per sq.ft. at depth of 50 ft. is 3125 lb.; total pressure equals 2000 × 3125 or 6,250,000 lb. or 3125 tons.

The total uplifting pressure is therefore 9374 tons plus 3125 or 12,499 tons. Against this we have weight of caisson, machinery and pig-iron ballast a total of 8437.5 tons leaving 4061.5 tons to be taken care of by water ballast.

Ballasted as above and with 32.55 lb. of air in the working chamber, the caisson will theoretically touch the bottom but not bear upon it. As it may be desirable to have the caisson press firmly on the bottom under these conditions it will be necessary to consider the total space available for additional water ballast.

It has been shown that the space available for ballast is about 200,000 cu.ft. The pig iron occupies 36,268 cu.ft. and 4061.5 tons of water will occupy 129,968 cu.ft. Total space occupied by iron and water ballast is 166,236 cu.ft. which amount deducted from 200,000 leaves 33,764 cu.ft. of space to be occupied by structural members, shafts, etc., and additional water ballast.

From these figures it appears that additional water can be admitted to ballast chambers to hold caisson firmly on the river bottom under the heaviest air pressure needed for the conduct of the work.

In order to sink and raise the caisson readily the ballast chambers will be provided with valves for the ready admission of water and with pumps for the discharge of ballast water with reasonable dispatch.

It has been shown that the maximum amount of ballast will be in the caisson when the trench has been ex-

cavated to subgrade and there is 32.55 lb. per sq.ft. air pressure in the working chamber. Under these conditions it has been shown that there will be at least 4061.5 tons of water equal to 162,236 cu.ft. or 1,216,770 gal. in the ballast chambers. Four 6-in. centrifugal pumps, each with a capacity of 3000 gal. per min., will empty all of this water in 102 min. But with all of the water out of the ballast chambers the caisson will float at a depth of 45 ft. and as it is only necessary to clear the caisson of the trench bottom in 50 ft. of water, it will theoretically be necessary to pump out only about 80% the above quantity of water for the caisson will float in 50 ft. of water with 937.5 tons or 300,000 cu.ft. or 225,000 gal. of water in the ballast chambers. From these calculations it can be readily seen that the ballast chambers can be emptied entirely in less than 1 hr. 42 min. and sufficient for manipulating the caisson in 1 hr. 23 min.

The flooding either ballast chambers or working space, it will only be necessary to furnish a sufficient number of flooding valves of proper size to fill these spaces in a very short time.

The space to be occupied by water ballast is to be divided and subdivided by longitudinal and transverse bulkheads so as to form separate ballast chambers. These chambers are to be so connected with the pumps and so interconnected with each other that any ballast chamber or any group of chambers can be emptied or flooded independent of all others. This arrangement facilitates very much the handling of the caisson.

The operation of sinking and floating a structure similar to the caisson under consideration is neither novel nor untried as is evidenced by the ease and rapidity with which the floating gates of the dry-docks in our Navy Yards are manipulated in docking and undocking vessels. The great floating dry-docks at New Orleans, Manila and elsewhere are operated in exactly this principle and battleships weighing ten thousand tons or more are lifted out of the water in a few hours.

There is, however, one condition in connection with this tunnel construction that is different from those existing in the operation of floating dry-docks and that is the possible interference caused by currents.

Inspection of the tide tables published by the U. S. Coast & Geodetic Survey shows that the currents at the site of the proposed tunnels run in opposite directions at different stages of the tide and that every six hours there is a period of slack water when no currents exist.

The maximum velocity is given at 3.1 miles per hour and the pressure exerted by such a current against a caisson 120 ft. long and 50 ft. deep is 127.6 tons. Tendency to displace the caisson is resisted by the pressure of the caisson on river bottom and by the sheathing driven below bottom of caisson as well as by the spuds which will be operated from the main deck.

The end of the caisson which rests over the finished portion of the tunnel is made about 4 ft. less in depth than the forward end and the long side walls. This shortening of the rear wall prevents the weight of the caisson from bearing too heavily on the unyielding masonry of the finished tunnel while the other portions of the caisson bottom bear more or less on the compressible river bottom.

This notch in the rear end of the caisson also permits the caisson to ride a finished portion of the tunnel when the caisson is being moved forward. The finished tunnel will thus serve as a guide for the caisson and also resist the action of the currents toward moving the caisson laterally.

The space which occurs between the bottom of rear wall of caisson and the roof of the finished tunnel where it projects under the rear end of the caisson into the working chamber after the caisson has been settled in place for a new tunnel section can be filled with bags of clay carefully packed to prevent air leakage and further protected by lowering the sheet piling on the rear wall until it rests on the tunnel roof.

Operations for moving and sinking caisson would be conducted as nearly as possible during periods of slack water when the currents are of low velocity or nonexistent.

The difficulty of moving caisson and resetting it in a current of the velocity of 3.1 miles per hour is evidently not very great for in constructing the Detroit River tunnels, sections of the lining of two tunnels 23 ft. in diameter and 260 ft. long were sunk in two hours in a current of about 3.4 ft. per sec. or 2.3 miles per hour.

In considering the remote possibility of the caisson escaping from its moorings and being carried away by the currents, it should be remembered that the caisson draws 45 ft. of water even when all the water ballast has been pumped out, consequently it cannot float beyond the confines of the dredged trench as it would run aground.

Sheathing

In considering the sheathing which is used in carrying the excavation 25 ft. below the bottom of the caisson, it should be borne in mind that the plan of procedure contemplates driving the sheet piling in advance of the excavation to a greater or less extent. The distance driven will be determined by the character of material penetrated, the absence or presence of boulders and the ease of penetration.

It will be necessary to increase the air pressure in the working chamber so as to exclude the water from the bottom of the excavation as the trench is deepened. As a result of this increase in air pressure there will be a pressure on the sheeting tending to force it against the material in the river bed back of the sheeting.

The maximum pressure will be exerted when the bottom of the trench has been reached 75 ft. below the surface of the water, for then the air pressure in the trench and working chamber will be 32.55 lb. per sq.in. or 4687.5 lb. per sq.ft., sufficient to resist the hydrostatic head of 75 ft. which exists outside of sheeting at the level of the trench bottom.

Considering the stresses in the sheet piling under these conditions of maximum air pressure, it is found that on a level with the bottom of the excavation the air pressure in the trench tending to push the sheeting against the banks is just equal to the 75 ft. of hydrostatic pressure which exists outside of the sheeting and tends to push the sheeting into the trench. These two equal and opposing forces counteract each other and there is no strain on the sheeting at the bottom of the trench.

As the air pressure within the trench and working chamber is uniform throughout, while the pressure against the outside of the sheeting decreases as the surface of the water is approached, the resultant pressure is from the trench outward and increases as the upper end of the sheeting is approached.

At the upper end of the sheeting, on a level with the bottom of the caisson 50 ft. below the surface of the water there is a hydrostatic head of fifty feet against the outside of the sheeting while within the trench at the same level the air pressure is equal to the hydrostatic head of 75 ft. The resultant pressure equal to a hydrostatic head of 25 ft., is the equivalent of 1562.5 lb. per sq.ft.

A sheet pile 12 in. wide and extending from the bottom of the caisson downward 25 ft. to the bottom of the trench would therefore be subjected to a pressure varying from nothing at the bottom to 1562.5 lb. per sq.ft. at the top. The tendency to force a sheet pile under such pressure outward is resisted by the material in the river bottom outside of the sheeting, and as ordinary soils have a safe bearing capacity of $1\frac{1}{2}$ tons per sq.ft., even the maximum pressure of 1562.5 lb. at the top of the sheeting is not sufficient to push it out of place.

As a matter of fact, the wall of sheet piling separating the air pressure within the trench from the hydrostatic pressure on the outside merely acts as a diaphragm to neutralize the comparatively small inequalities of pressure between the two opposing forces.

In designing this sheeting it should be made stiff enough and strong enough to take with safety the maximum pressure of 1562.5 lb. per sq.ft. for a span of from six to ten feet to take care of soft spots, or holes, cavities made by dredging which may exist in the banks of mud, sand and gravel against which the sheeting will bear.

Furthermore, when the caisson is located over a rock bottom it may be necessary to drive sheeting to rock, make a tight connection with the rock, brace the sheeting across the trench and then reduce the air pressure in the trench to normal. In such a case the pressure will be from nothing at top and the maximum pressure would be at the bottom of the sheeting. The sheeting should be sufficiently strong to resist this pressure for a span of about ten feet between waling pieces and braces.

To make a practically air-tight sheeting a tongued-and-grooved sheeting of yellow pine, such as is ordinarily used on deep trench work, suggests itself. As such a material, [illegible] might not be strong enough for all conditions. A strong but tight sheet pile can be made by bolting [illegible] timbers to each side of a steel I-beam, thus giving the composite beam or sheet pile. The timber members are to be tongued and grooved in the usual manner, thus securing a sliding joint with the adjoining sheet piles which can be maintained practically air-tight.

Each sheet pile will be attached to a wall of the working chamber by means of a guide built of steel in which the sheet piles are readily slid up or down. This sliding connection will be so constructed that the sheeting cannot be displaced laterally at any location without removing the steel portion of which the guide is attached.

Sheeting constructed in this manner will be prevented from drifting when driven into the river bottom, thus insuring [illegible] with the bracing [illegible] and bracing [illegible].

Air Leakage

There will be practically no excessive air leakage at the bottom of the excavation, for here the outer and inner pressures are equal. But when the excavation has been carried down to subgrade there is a difference of about 11 lb. per sq.in. between the pressure within the work chamber and on the outside at the level of the bottom of the caisson.

Under these conditions the air tends to escape between the back of the sheeting and the walls of the caisson and thence under the bottom of the caisson and through the water into the free air. To reduce this leakage it will be advisable before starting to drive the sheeting to pack bags of clay under the inner edge of caisson and fill all cavities which may exist between caisson bottom and river bottom with clay. These bags of clay are to be so placed that the sheet piles, as they descend, will press firmly against the clay and make a close contact.

After the sheet piles have been carried to the full depth, the space between sheet pile and caisson wall can be calked with oakum or other suitable materials or the space may be "mudded up" with clay in the usual way.

Advantages of This Method of Construction

From the foregoing description and discussion it is evident that this method of tunnel construction offers the following advantages over the shield method:

1. Safety from Blowouts—The balanced pressures in the "horizontal heading" or place of operations removes all danger from blowouts and flooding of working chamber and thus assures (a) the safety of the workmen, (b) steady progress in the work of construction.

2. Easier Grades—As no cover other than the caisson is required the tunnels need not dip as far below the river bottom as shields necessitate and hence easier grades can be followed.

3. Exact Line and Grade—The tunnel may be built to exact line and grade, results which are approximated in the shield method by making the diameter of the tube larger and correcting deflections from line and grade in the inner concrete lining of the tube.

4. Foundations—The river bottom may be reinforced with piles or by other methods should conditions demand it, before the tunnel is built.

5. Better Construction—As the tunnel is accessible from all sides the work of construction is open to thorough inspection and the tunnel may be built of riveted steel plates surrounded with impervious concrete. This gives a tighter, less flexible and more permanent structure than one built of cast-iron plates bolted together and placed directly against the river mud. The expensive operation of pumping grout blindly into the mud in the hope that eventually it will fill all cavities back of the tunnel lining is also obviated.

6. Materials Handled More Economically and Expeditiously—The caisson resting firmly on the river bottom forms a stable dock of ample area, equipped with derricks and hoists for the handling of excavated materials direct to scows and lighters and for the receiving of materials of construction such as sand, gravel, cement, steel, timber, etc., from lighters and barges moored alongside the caisson.

By this arrangement the cost of conveying excavated material through the finished portion of the tunnel to the shaft, hoisting it at the shaft, dumping it into wagons, carting it through the streets and dumping it on barges at the dock is avoided. Similar operations in bringing materials of construction to the heading are dispensed with.

7 WORK DONE MORE ECONOMICALLY AND EXPEDITIOUSLY—It is evident that with an area 100 ft. long and 40 ft. wide uncovered for work and protected from interruption from "blowouts" more men can be employed and the work finished more quickly and economically than by working through shield doors against a tunnel face 20 ft. in diameter.

There is also less labor involved in hoisting or lowering materials through shafts directly overhead than there is in conveying them through the finished tunnel to a shaft on shore.

8 GENERALLY MORE ECONOMICAL—In addition to handling materials and labor more economically there is a considerable saving in the amount of plant and in the operation of the same, in the amount of piping, cost of building shafts, cost of pushing shields through rock tunnels on the Manhattan side of the river from the shaft on shore to where the rock dips below the tunnel line in the river deposit, cost of property where plants are located, cost of covering part of river bed with clay and cost of pumping great quantities of compressed air which escapes through the river bed. The balanced pressures in the heading, the tightness and comparatively small volume of space under air pressure reduce the requirements for air to a minimum and hence reduce the number of compressor units required.

The location of the plant on the caisson directly above the "heading" reduces the amount of piping required, while the location of shafts and air locks directly over the operations does away with the necessity of tracks and cars used in the shield method to convey materials from the heading to the shaft on shore and *vice versa.*

The setting up of shields in the working chamber of the caisson as the river tunnel approaches the shore and the subsequent use of the caisson as a shaft for handling materials does away with the necessity of sinking a shaft on shore. This is a great saving as the cost of such a shaft is large.

As the caisson covers the section of the tunnel under construction there is no occasion to cover the river bottom with a blanket of clay for there is no excessive air leakage.

ESTIMATED COST

An estimate carefully made in detail shows the following costs exclusive of contractors' profit:

Caisson with machinery complete	$400,000
Operating caisson	118 per day
Interest charges	66 per day
Supervision, office and field	183 per day
Tow boat for men	75 per day

With the above overhead charges and the actual labor and materials estimated at present market prices, a tunnel 18 ft. in diameter made of ⅜-in. steel plates and surrounded by 3 ft. of concrete would cost if constructed by this "caisson" method $245 per lin.ft. through mud, sand and river deposit and $370 per lin.ft. through rock.

The estimated cost of such a tunnel built on the location shown for the new subway tunnels from Whitehall St., Manhattan, to Montague St. Brooklyn, would be $3,176,330. If to this cost 25% be added for contingencies and the profit of the contractor, a reasonable contract price for the tunnel would be $3,975,412 or practically $4,000,000.

The lowest bid received by the Public Service Commission for the construction of a tunnel to be built on the same route, but according to the plans and specifications of the Public Service Commission, was $6,368,550 if built alone, and $5,974,809 if built in conjunction with the tunnel from Old Slip Manhattan to Clarke St.,

The Explosibility of Grain Dust

A number of disastrous grain-dust explosions in elevators and mills have occurred during the past few years and have attracted general attention from engineers. An arrangement was made between the U. S. Bureau of Mines and representatives of various milling interests for a scientific study of the explosibility of grain dust and of methods to prevent such explosions. Work was started late in 1913 under direction of G. A. Hulett, Chief Chemist of the Bureau of Mines, with D. S. Price in charge of field investigations and H. H. Brown in charge of laboratory work. A preliminary report has been issued from which the following data are abstracted.

An investigation was made of 13 explosions which have occurred since 1905; of these, three were in Iowa, three in New York, two in Illinois and one each in Vermont, Indiana, Kansas, Ohio and Texas. The explosions were distributed among various lines of milling as follows: cereal mills 4, elevators 3, feed mills 2, starch factories 2, glucose factory 1, flour mill 1. In these 13 explosions 78 men were killed and 119 injured; the total property damage was in excess of $2,000,000. The relative freedom of flour mills from explosions compared with the magnitude of the industry is noteworthy; this has been attributed by millers to the elimination of the old dust bin, which took place after the disastrous explosions in the great flour mills of Minneapolis a quarter century ago.

Various wheat, corn and oat dusts from different parts of mills and elevators were analyzed and their ignition temperatures and explosion pressures were determined. As the basis of comparison, Pittsburgh standard coal dust was used in accordance with the Bureau of Mines practice.

In general, it was found that the grain dusts are more inflammable than coal dust, higher explosion pressures being developed in most cases and especially at the lower temperatures (between a range of 900° to 1300° C). Dusts from oats and yellow corn appeared to be more inflammable than dust from wheat. The explosion pressures with dried dusts were some 16 times greater than with the undried.

The investigators found several causes generally assigned to the explosions noted: open-flame lights, conflagrations, foreign materials in grinding machines, sparks from electric motors, switches and circuits, and static electric discharges from belts. It was found that many of the mill explosions and fires originated from foreign materials in the grinding machines and it is recommended that some means be found of removing such materials before the grain reaches the mills. It is also recommended that only a completely guarded electric lighting system be used, that portable electric lanterns be used in place of flame types, and that receiving bins from grinders be kept as small as practicable to decrease the space for dust clouds.

Granite-Block Pavement as Smooth as Asphalt

A granite-block pavement as smooth as one of sheet asphalt seems an anomaly, yet engineer visitors to Worcester, Mass., may satisfy themselves of the truth of this statement, that the granite-block pavements of Main and Front Streets, which have been down ten or more years, are as smooth as ordinary sheet-asphalt pavements which have been down two or three years. Fig. 1 is from a photograph of Main St. just after a street-sprinkling car had passed, so that the wet surface reflected the light and brings out all the imperfections.

A NEW YORK ENGINEER'S OPINION—Worcester, Mass., was probably the first city to make use of the cement-grout joint. The spaces between the blocks were filled with stone screenings and then poured full of the grout. The result was very satisfactory.

There are advantages and disadvantages in a joint of this kind. It makes a smooth, even pavement, and one that is easily cleaned. It presents little resistance to traffic, and brings the wear of traffic vertically on top of the blocks so that the pavement is very durable, but becomes smooth and slippery under wear.

It is extremely necessary that the grout should become thoroughly hard before any traffic is allowed on the pavement, otherwise the blocks will be loosened and the [illegible] so that the filling becomes little, if any, better than sand.

Pavements thus laid become practically continuous, giving off a metallic sound under traffic. The hardened grout, being a good conductor of sound, transmits the noise readily from block to block. Where the grout is [illegible], however, and the street is kept free from traffic until the grout has thoroughly set, the pavement will be very satisfactory. It is the smoothest form of stone pavement that has been laid in the United States.—Geo. W. Tillson, "Transactions," Am. Soc. C. E., LXXV, pp. 327-29.

FIG. 1. [illegible] GRANITE-BLOCK PAVEMENT, [illegible] MASS.

These extraordinarily smooth granite-block pavements are due to several reasons: (1) a fine-grained, uniform granite, which is not so hard as that ordinarily specified or used; (2) experience and skill of the municipal laborers, acquired by many years' continuous experience in laying stone-block pavement; (3) a rich portland-cement grout and stone screenings for joint filling, and the method and care in application; (4) a fairly heavy traffic, which wears off the original roughness and irregularity.

The Blocks

A digest of the Worcester specifications follows:

SPECIFICATIONS AND CONDITIONS—The stone blocks are of granite of a durable, sound and uniform quality, each measuring on its face or upper surface not less than 7 nor more than 12 in. in length, and not less than 3½ in. nor more than 4½ in. in width and not less than 6 nor more than 6½ in. in depth for the larger size blocks, and not less than 4 nor more than 4½ in. in depth for the smaller size blocks.

The blocks used on each piece of work are uniform in depth and are of the same quality as to hardness, color and grain. All edges are sharp and straight, and at approximately right angles with each other, and dressed so as to form, when laid, close end and side joints, with fair and true surfaces on top, bottom and ends, and are to be in all respects equal to the specimen blocks furnished by the contractor.

All blocks delivered must be satisfactory to the Street Commissioner, and any block which does not in his opinion conform strictly to these specifications may be either rejected or caused to conform to the requirements of the contract at the expense of the contractor. The blocks are delivered as ordered, upon [illegible] at such times and in such quantities as the Street Commissioner may direct, and no liability attaches to the city until their acceptance is made in writing.

The Pavement

The pavements are laid by the Street Department with municipal day labor, according to specifications of the City Engineer, a digest of which follows:

FOUNDATION—The foundation is 4, 5 or 6 in. of 1:3:6 portland-cement concrete.

CUSHION—Upon the concrete foundation is a layer of clean sharp screened dry sand, not less than 1½ in. thick, evenly spread to the finished crown. If the sand is not dry it must be made so by artificial heat before being spread. The sand cushion is prepared at least 25 ft. ahead of the laying.

LAYING THE BLOCKS—The blocks are laid with their longest dimension perpendicular to the center line of the street, except at street intersections where the blocks are laid diagonally. Each course of blocks is of uniform width and so laid that all longitudinal joints are broken by a lap of at least [illegible] [illegible] [illegible]

FILLING JOINTS—[illegible]

[illegible]

[illegible]

FIG. 2. CLOSE VIEW OF FRONT ST. GRANITE BLOCK

applying the grout. After completion the pavement is kept damp and is protected from traffic until the grout has thoroughly set and hardened. [This is one of the most important provisions, for it insures that grout is given a chance to stick to the surface of the blocks.]

COST DATA—These pavements cost, complete with 1:3:6 portland-cement concrete foundation, from $2.75 to $3.25 per sq.yd. The blocks cost about $54 per 1000 for 4-in. size and $60 for 5-in.

CONCLUSIONS—THE SECRET OF SMOOTH GRANITE-BLOCK PAVEMENTS—Fig. 2 is a close view of the Front Street pavement. Although the blocks are a bluish-white granite (Fig. 3) when placed, they wear a slaty color. The joints wear with the same uniformity as the granite itself so that the surface is smooth and free from depressions. The pavement is not slippery like sheet asphalt, but has a gritty feeling.

The pavement when first placed is comparatively rough, but the grout is broomed into the surface depressions and granite bumps wear smooth; so that, if not disturbed for subsurface construction, the pavement is actually in much better condition after ten years' use than when put down; and absolutely nothing has been spent for maintenance.

The secret is not so much the method of construction, perhaps, as in the character of the granite itself. The granite used in Worcester and Lowell, Mass., where pavements of the same remarkable smoothness have been attained, all comes from New Hampshire quarries of the Hildreth Granite Co., which are within a radius of 25 mi., including the towns of Concord, Marlborough and Milford. While varying much in color and appearance, these granites all have the same general physical characteristics.

Typical of all is the so called "Concord granite" described as follows:

Concord granite is a muscovite-biotite granite of medium bluish-gray color. The texture is fine to medium, somewhat porphyritic, with sparse, slender, isolated feldspars up to 0.5 in. Although the micas occur in very minute particles, especially the biotite, they measure up to 0.2 in. and exceptionally 0.4 in.

Its constituents in descending order of abundance are: Slightly bluish, translucent potash feldspar inclosing particles of quartz and of soda-lime feldspar; clear to pale amethystine quartz with hair-line crystals, probably of rutile, and with cavities in sheets which in some sections are parallel; milk white striated soda-lime feldspar, more or less kaolinized and centrally micaized; with white potash mica (muscovite); and black mica (biotite), some of it chloritized, generally in smaller scales than the muscovite. In some cases the mica plates have their flat sides parallel to the rift direction; in some the biotite appears to predominate over the muscovite, possibly owing to the alignment of its scales.

The accessory minerals are: magnetite, apatite, zircon and rutile. Purple and white fluorite occurs here and there on and near joint planes. Calcite and quartz are associated with it on these joints. Secondary minerals are: kaolin, muscovite, in veinlets, a white mica without potash, chlorite and calcite.

FIG. 3. CHARACTER OF BLOCK USED IN WORCESTER

The specific gravity is 2.64-.65 or 165.6 lb. per cu.ft. The polish is fair, but the abundant mica plates and size of some of them do not favor the durability of the polish under long-continued outdoor exposure.*

These granites contain a relatively large quantity of finely divided mica. The quarry men believe that to this is due the tenacity with which the grout clings to these blocks, the lean grout following the mica filaments into the interior of the blocks. These and the soda-lime felspars, more or less kaolinized, must make the porosity relatively high for granite. The crushing strength is from 18,000 to 23,000 lb. per sq.in. The fact that as a polished stone this granite weathers considerably is probably proof of its porosity, and possible lack of durability as a building stone; but nevertheless tends to make it an ideal paving material.

The city engineer of Worcester is F. A. McClure, to whom we are indebted for much of this information.

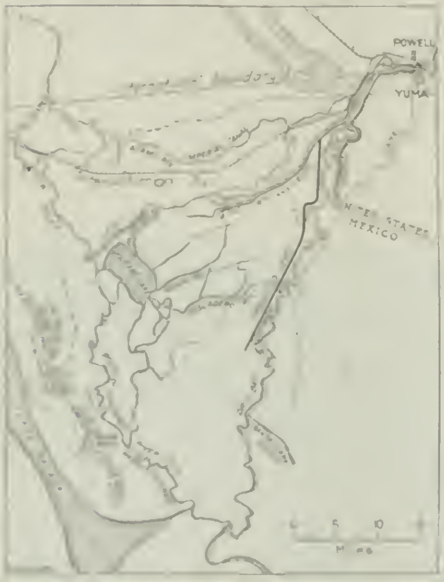
A Suggested Plan for Developing the Lower Colorado River*

By Walter D. Smith†

As irrigation engineer, United States Reclamation Service, and the first to be stationed on the lower Colorado River, the writer has had very exceptional opportunities to study the hydrography of that river. From 1902 to 1906 he had charge of the hydrographic measurements on the lower Colorado made by the Reclamation Service and the Geological Survey, including observation and official reports of all that occurred at the Imperial Canal heading, in the United States and in Mexico, the diversion of the river to the Salton Sink, and the work done in returning it to its old channel.



Map of the Lower Colorado Delta and Imperial Valley, California-Mexico

([illegible] from "Engineering News," [illegible])

In 1909 he was a member of the first party to make a [illegible] of reconnaissance into Mexico for the Reclamation Service. Further study and a trip over the region in June, 1914, has confirmed him in his opinion as to the [illegible] methods of controlling the floods.

Importance of the Project.—At a recent meeting of the Engineers and Architects' Association of Southern California, A. P. Davis, Chief Engineer of the United States Reclamation Service, expressed the opinion that the Colorado River Development is a bigger project than the Panama Canal. Mr. Davis has been connected with both projects.

There is enough water, if properly stored, to irrigate more than [illegible] acres, and that amount of land is available. Estimating the cost of putting the water on land at $[illegible] per acre, and the value of land with water at $[illegible] per acre, the net profit would be $[illegible]. Estimating the value at $[illegible], the direct net profit would be $[illegible]. With the opening of the Panama Canal and the flood of commerce which will pour through, there will be on the Pacific Coast a plentiful supply of labor for construction work and an enormous demand for land. Our products will have access to the markets of the world through the harbors at Los Angeles and San Diego; also perhaps over perfect railway grades through a harbor on the Gulf of California. The Colorado River country cannot be developed too rapidly.

Rapid development, however, may be attended with certain weakness. Rapid as has been the development up to the present time, it could have been more rapid and more secure if there had been a central organization with a single comprehensive plan. An illustration of this is found in the disaster of 1905. Today the situation is more complicated than it was in 1905 and there is more at stake. There should be some way of uniting the efforts of all who are concerned—private corporations, mutual water companies, reclamation service projects, War Department, individual landowners in Mexico and in five states of this country.

Fortunately in 1905 the only cost was retarding development of the Imperial Valley about two years and $[illegible] in tangible damage and expense. It might be much worse another time. Today the Colorado River floods are not being watched and guarded against as carefully as they should be. Everybody's business is nobody's business.

A Plan to Fit the Case.—The writer suggests the organization of a permanent commission composed of five members, to be known as the International Colorado River Commission, to have full responsibility and authority subject to the approval of the legislative bodies of the two countries, as follows:

1. To adopt a general plan of development to use the natural resources regardless of international boundary lines.

2. Apportion cost of same, decide method of financing and order of construction.

3. Determine by whom the work shall be done, what portion by the United States and by Mexico, what portion by private corporations, mutual companies, Reclamation Service, War Department, and what if any directly by the Commission; by whom controlled and operated when completed.

4. To review and report annually on the progress of the work and to have direct charge of all completed [illegible], [illegible], reservoirs and dams on the river itself.

5. To adjust rights, national, state and individual.

Each commissioner to serve five years subject to recall at any time, the term of one member to expire each year. Two to be chosen by a water users' association composed of all irrigators using Colorado River water, and by landowners in the districts where Colorado River water is to be provided, the water district to be [illegible] at first by the [illegible] of the Reclamation Service; one to be appointed by the President of the United States; and one by the President of Mexico.

By such a plan all interests will have due representation and all causes, either individual and national, will be protected. The landowners who have most at stake and who will pay much of the cost will have sufficient

*[illegible] of the [illegible] "Engineering News," [illegible]

†[illegible], U. S. Reclamation Service, [illegible]

direct authority to get results promptly and efficiently. In this way the two countries can agree upon progressive methods of development and land ownership.

ENGINEERING PROBLEMS—The engineering problems to be solved in the accomplishment of this work are:

(1) Store flood waters; (2) separate water from silt; (3) put water on land for irrigation; (4) keep flood water off the land; (5) drain irrigated land and use water again; (6) dispose of surplus flood water; (7) dispose of surplus silt; (8) develop electric power; (9) perhaps build land with silt.

The remainder of this article will deal primarily with points 6 and 7. The other points have already been considered by others and can be accomplished by proved methods. The most urgent problem now is flood control. It is even more important to protect and insure the territory already developed than to develop new territory. Insurance is worth while. Land in the Imperial Valley sells for $150 per acre which in the San Bernard-

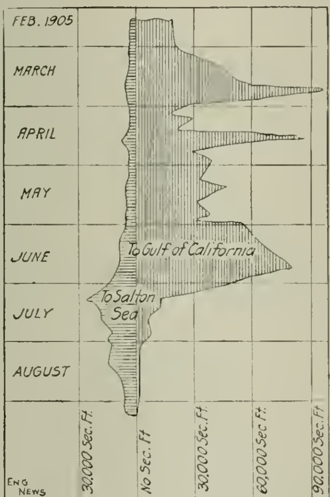


DIAGRAM SHOWING RATE OF DIVERSION OF COLORADO BY IMPERIAL CANAL, 1905

(Amount of water diverted to the Imperial Valley and Salton Sink from February to June, 1905, was only 10 to 13%; from July 1 to 15 it increased to 70%.)

ino, San Gabriel and Los Angeles valleys would bring $500 per acre. Also in most of the territory yet to be developed the flood problem is the most important, the most difficult and the most liable to be neglected. It probably will be impossible to control the floods completely by storage reservoirs alone.

To keep the river out of the Salton Basin by a levee along the high land north of Bee River and Volcano Lake is not entirely satisfactory. It will be expensive and there is danger of the river breaking through. Also the water cannot reach the ocean without using a very large tract of land as a settling basin.

To force the river into its old channel, the shortest route to the ocean, gives a better grade but no satisfactory settling area. With its load of silt amounting each year to 75 sq.mi. one foot deep, this will be increasingly expensive and insecure. If the silt could be removed this expense and danger could be eliminated.

WHERE TO PUT THE SILT—The writer suggests that the proper place to put the troublesome part of the silt is in the Salton Basin. In this way the Imperial Valley, the delta in Mexico, and the Yuma Valley can be insured against flood as they never can be by levees alone. As an additional insurance device the controlling gates might be made large enough to take a considerable portion of the flow at flood, using them as a safety valve.

When the system of storage reservoirs on the headwaters is completed, the Salton Sea may be sufficient to take all the remaining floods, and the channels to the ocean can be used as canals.

With all the power of the federal government the lands along the Mississippi have never been insured against flood, perhaps never will be by levees alone, and only at great expense otherwise. The same would be true of the Colorado if there were no Salton Sink.

The possible incidental advantages of this plan are:

1. Drainage for the Imperial Valley, of all land on north slope of the delta, and lands of the Yuma Project.

2. Eliminating expense of removing silt from canals. Sink where surplus drainage from the Imperial Valley can be used for irrigation.

7. Straightening and making permanent the Alamo Channel below Sharp's or Holt Heading.

8. Shifting of Alamo above Sharp's Heading to a permanent location closer to the mesa, increasing area of delta land easily available for irrigation.

9. Increased opportunities for development of electric power.

The details of this plan are simple. The cost will be moderate. The plan is to sluice the silt into the Alamo Channel by controlling gates on bed rock at Pilot Knob. With the heavier silt removed the old channel below Pilot Knob will scour deeper and straighter. All that is necessary is to scour deep enough to carry the flood waters without levees. Some bank revetment may be required. At 200 ft. below sea level, the elevation which the Salton Sea attained in 1907, the evaporation amounts to 2,000,000 acre-ft. per year. This amount minus the drainage from the Imperial Valley would be available for the work of sluicing. The larger the gates at Pilot Knob, the less the total amount of water required for that purpose, because: (First) the greater the discharge the greater the percentage of silt possible to carry; (second) the more the gates can be depended upon as a regulating safety device at crests of floods, the less the amount of silt necessary to remove.

CONCLUSION—The piecemeal methods which necessarily have been used up to this time have proved expensive and dangerous. The development of the Colorado River country is a case where prompt and comprehensive work is more economical than slow and partial development. With the knowledge and experience gained in the past such action is now possible. Construction can go forward rapidly and surely as soon as a practical permanent organization is effected.

Sewage Disposal by a Public Service Company is not entirely out of date yet, it appears from recent press reports from Collingswood, N. J. The Collingswood Sewerage Co. is petitioning the New Jersey State Public Utilities Commission for permission to increase its rates from $9 to an average of $20 per house. The sewerage company alleges that it has lost $92,000 in its operations of a sewerage system and disposal plant. Oct. 20, has been set for a final hearing on the case. Collingwood is in Camden County and has a population of about 5000.

Brooklyn Sewage-Experiment Plant

By George T. Hammond*

SYNOPSIS—A notable addition to the list of municipal experiment plants for the treatment of sewage has been made by the Borough of Brooklyn. This plant [illegible] for [illegible] sedimentation in Dortmund and Imhoff tanks, a special [illegible] tank and Imhoff sludge beds, a [illegible] tank and [illegible] siphon, sprinkling filters, both ordinary and [illegible] by means of compressed air, and "[illegible]" sedimentation tanks. [illegible] studies are proposed, as also tests of a [illegible] screen and a [illegible] filter. The sewage flow to all units is measured by calibrated orifices in connection with [illegible] and [illegible]

[illegible] station and sewage-treatment plant, on Jamaica Bay. The studies there being made are intended to assist in designing new sewage works for the 26th Ward, in place of the present outgrown plant, and also to assist in designing works for other portions of Brooklyn. Part of the plant was put in operation on Oct. 1, 1913, and most of the rest on Jan. 1, 1914.

At the 26th Ward site and also at other available sites for disposal works for Brooklyn the problem is to provide works which will produce an effluent suitable to be discharged into tidewater, which works must be located on marsh land with a surface only slightly above sea level.

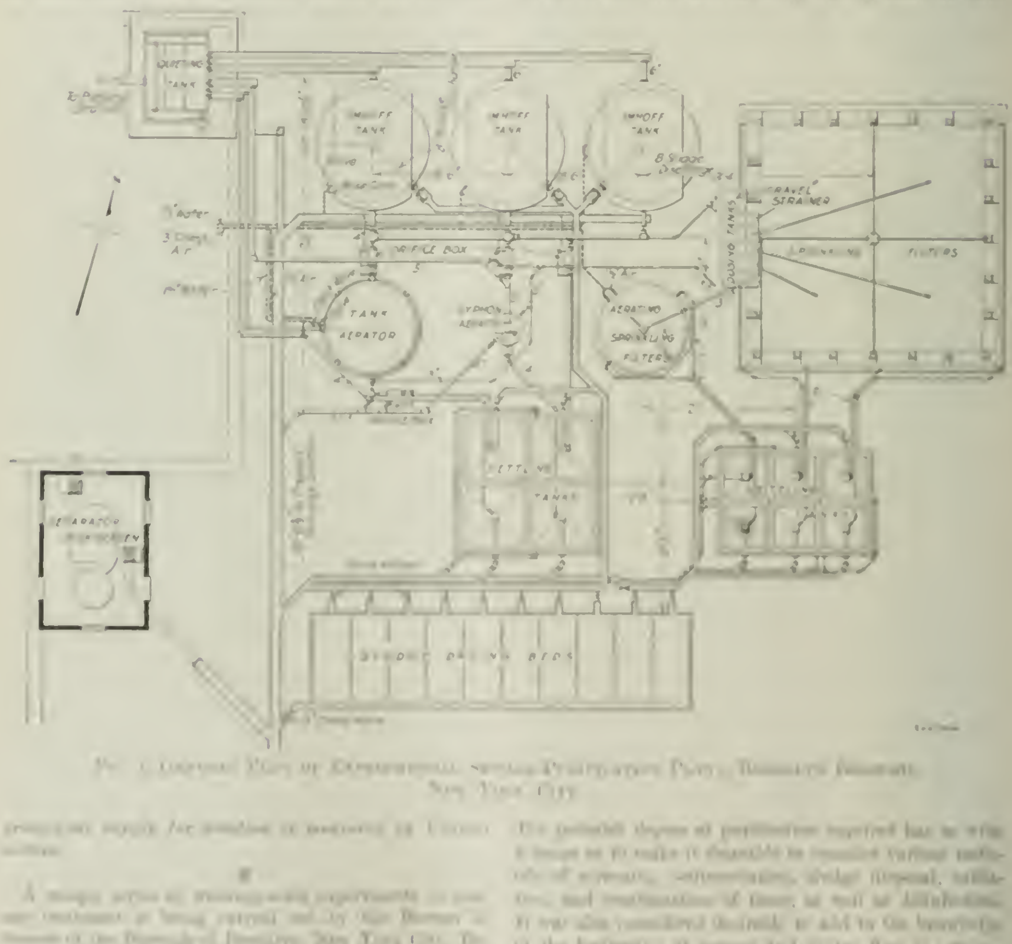

Fig. 1. General Plan of Experimental Sewage-Purification Plant, Brooklyn Borough, New York City

[illegible] for [illegible] in [illegible]

A [illegible] series of [illegible] experiments in sewage treatment is being carried out by the Bureau of Sewers of the Borough of Brooklyn, New York City. The experimental plant is located at the 26th Ward pumping

The [illegible] degree of purification required has to [illegible] [illegible] so as to make it desirable to consider various methods of screening, sedimentation, sludge disposal, filtration, and combinations of these, as well as disinfection. It was also considered desirable to add to the knowledge of the hydraulics of sewage and sludge flow in sewage-treatment plants and the effect of very cold weather on exposed sprinkling filters. The opportunity to study the effect of shape and direction on the operation of the various experimental units was also seized.

For the foregoing and other reasons all parts of the experimental plant were placed above [illegible] and [illegible]

*[illegible] Engineer, Bureau of Sewers, [illegible] Brooklyn, N. Y. [illegible]

accessible for observations on sewage and sludge and on the structures themselves. For study there were selected a Reinsch-Wurl screen and a Moore vacuum filter (or strainer); a Dortmund tank for plain sedimentation,

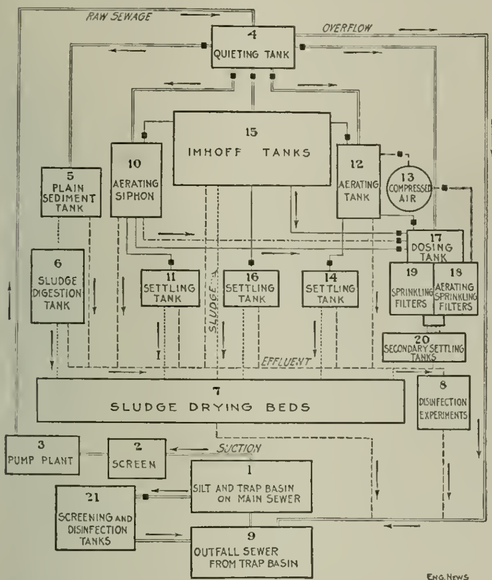

FIG. 2. DIAGRAM SHOWING RELATION OF APPARATUS IN VARIOUS STAGES OF OPERATION AND EFFECT ON SEWAGE, BROOKLYN SEWAGE-EXPERIMENT STATION

coupled with an independent sludge-digestion tank, and also three Imhoff tanks of different depths, coupled with sludge beds (the latter also being available for sludge from other units); an aërating siphon and an aërating tank, each supplied with compressed air, ordinary sprinkling filters and sprinkling filters supplied with compressed air; secondary Dortmund settling tanks receiving effluent from the aërating siphon, aërating tank and Imhoff tanks; and disinfecting apparatus. To aid in the hydraulic studies and in keeping accurate quantity records there were provided a knife-edge weir 25.84 ft. in length (ENG. NEWS, Apr. 9, 1914), in the outfall sewer; a quieting tank to receive the sewage from the pumps and distribute it by gravity to the various primary elements of the experimental plant; various orifice boxes and calibrated orifices to measure the flow of sewage to each unit; and Venturi meters to determine the volume of air used for aëration.

Fig. 1 shows the actual layout of the plant. The sequential relations of the various parts and processes are shown by the diagram, Fig. 2. A general view of the plant is shown by Fig. 3.

The large district from which the sewage used in the experiments comes is sewered on the combined plan. The sewage reaches the 26th Ward station in two 12½-ft. twin sewers, which terminate in a silt chamber. The latter is continued, in turn, by an outfall flume to tidewater. A 48-in. bypass conveys the dry-weather flow from the silt chamber to the old treatment works, from which it is pumped back into the flume.

The sewage for the experimental plant is drawn through a 12-in. suction pipe to a 1,200,000- and a 650,-000-gal. direct-acting steam pump, and is discharged through an 8-in. pipe 180 ft. long into the quieting tank already mentioned. The maximum lift is 40 ft. After supplying the quieting tank for some time with unscreened sewage it is proposed to try, successively, screens of different mesh on the 12-in. suction pipe. The Reinsch-Wurl screen will be tested with raw sewage, which has not gone to the quieting tank. The air for aëration purposes is supplied by a duplex air compressor, automatic in stopping, starting and speed. The compressor has a rated displacement capacity of 228 cu.

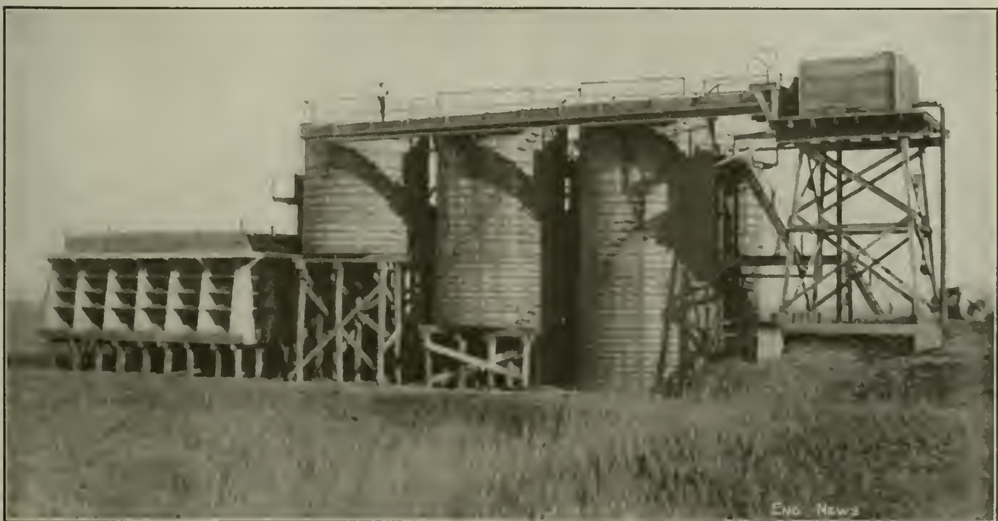

FIG. 3. GENERAL VIEW OF BROOKLYN SEWAGE-EXPERIMENT PLANT

[illegible] of air per min. and discharges into a receiver 24 in. in diameter and 72 in. high.

The maximum elevation of the land at the site of the experimental plant is 1.5 ft. above high water. The sludge beds were made the governing elevation of the experimental plant, with their surfaces at 2.67 ft. above mean high water. The elevation of the quieting tank was fixed so as to give a gravity flow throughout the plant. For this purpose the constant level of the sewage was set at 16.12 ft. above datum, or 12.92 ft. above the invert of the main outlet of the sludge-bed underdrainage system.

In general, the structural elements of the plant are of wood, but concrete was used for the Dortmund settling tanks, and for the ordinary sprinkling filters, and steel for the special sludge-digestion tank.

QUIETING TANK—By referring to Figs. 1 to 3, it will be seen that the center of operations is the quieting tank, which occupies the commanding elevation already noted. This tank is 5 ft. deep and 12 ft. 3 in. by 8 ft. 10 in. in plan. In its interior, each end is divided off by a partition, forming overflow chambers, which are connected with the waste pipe; the main chamber is between these internal partitions, and is 9 ft. in length by 8 ft. in width. Each end partition is cut down to the water line a horizontal distance of 3 ft. from the outlet side of the tank, forming an overflow weir, designed to maintain a constant hydraulic head over the outlet orifices. Two baffles are placed lengthwise of the tank, normal to the line of flow. The baffle nearest to the entrance of the sewage extends 3 ft. upward from the bottom, and is 2 ft. 6 in. from the entrance side of the tank. The other baffle extends downward from the top of the tank to within 1 ft. of the bottom, and is 2 ft. 6 in. from the first baffle, parallel with it, toward the outlet side. Thus the sewage, which enters submerged, rises over the first baffle, and then passes downward under the second, before entering the constant-level part of the chamber, from which it is fed to the various units through adjustable orifices.

ORIFICES—In the side of the main chamber of the tank, opposite to the entrance of the sewage, are placed six outlet orifices, each provided with an adjustable opening having a calibrated scale, which may be set to any rate of discharge within its range of capacity.* These orifices discharge directly into flumes that lead to the various experimental units, each orifice into a flume which it serves. The orifice boxes installed throughout the plant, with their weirs, are designed upon the same principle as the quieting tank. They were included in the general contract for the experimental plant.

A separate contract was made with the Wallace & Tiernan Co., Inc., of 136 Liberty St., New York City, for supplying, installing and adjusting in place the air [illegible] fixtures and also the compressed-air [illegible] to the [illegible] devices. The specified capacity of the [illegible] ranged from 150,- and to 500,000 gal. per 24 hours. As already stated, [illegible] are used to control the flow to each unit of the plant.

SEWAGE CLARIFICATION AND SLUDGE DISPOSAL

A considerable amount of the [illegible] was devoted to sewage clarification and to sludge reduction and disposal. For these purposes tanks, Dortmund and Imhoff tanks were used, as well as a separate sludge-digestion tank and sludge-drying beds.

DORTMUND TANKS—Of a group of four Dortmund tanks, one is used for primary sedimentation and three for secondary sedimentation, the latter receiving the effluents from the aerating siphon, aerating tank and the Imhoff tanks. Each Dortmund tank is of concrete, 8×8 ft. in interior plan, and 8 ft. deep from the water line to the lowest point in the pyramidal bottom. The inflow is through a 4-in. central down-pipe and the outflow through V-notches, two on each side. The sludge from the primary tanks goes to the sludge-digestion tank and that from the secondary tanks to the sludge-drying beds, in all cases without pumping.

IMHOFF TANKS—The three Imhoff tanks, which differ only in depth and cubical capacity, supply settled sewage or effluent to seven experimental units, all of which may be in action at the same time: (1) The ordinary sprinkling filters; (2) aerating tank; (3) aerating siphon; (4) the special sprinkling filters, with compressed-air aeration; (5) a secondary settling tank; (6) disinfection tanks; (7) Moore mechanical vacuum filter tanks.* Sewage discharged to the various sprinkling filters may be passed through a gravel roughing filter. Sludge for testing and drying goes to the drying beds and surplus sludge is discharged into the sewer.

The only parts of the Imhoff tanks which are of the same depth in all three tanks are the scum or baffling boards, which dip 18 in. into the sewage. Later on, different baffling arrangements will be studied. Each tank is 15 ft. in diameter, with depths from the water line downward as follows:

	Total depth, ft.	Sedimentation-chamber depths, ft.	
		Vertical side	Center
Tank 1	[illegible]	[illegible]	12.97
Tank 2	[illegible]	[illegible]	10.6[illegible]
Tank 3	[illegible]	[illegible]	7.[illegible]

The floors of the upper sewers or sedimentation chambers have a slope of about 45°. The floors do not lap, as is usually the case, but below them there is a timber shield, with upper slopes of 45°. In the [illegible] no collection of settlings has remained upon the slopes. The tanks are covered with a flat removable roof. The tanks have been in satisfactory operation since [illegible] 1, 1914.

SLUDGE DIGESTION TANK—This tank (the location not shown on the accompanying plan) is of steel, made to be water-tight and air-tight. It is 5 ft. in diameter and 15 ft. in depth, set vertically in the ground so that the most of it is above the water line of the [illegible] sedimentation tank, from which it receives sludge. The effect of varying temperature or of chilling from ground water is minimized by providing a double shell, with a closed air space between the shells. The sludge is drawn from the primary Dortmund tank through an [illegible] line to the digestion tank. The digested sludge is passed to the sludge-drying beds.

SLUDGE-DRYING BEDS—There are [illegible] beds of [illegible] half [illegible], each [illegible] ft. in plan. The [illegible] is [illegible] of "[illegible]" [illegible], surfaced [illegible] of coarse sand, the whole supported on a [illegible] platform.

AERATION DEVICES

[illegible] raw sewage from the quieting tank or Imhoff tank effluent may be subjected to aeration in (1) an aerating [illegible]

*See [illegible] detailed description, with illustrations, in the [illegible] and [illegible] of this issue.—Ed.

*The last items are not yet in use.

ing siphon, (2) an aërating tank, (3) sprinkling filters equipped with a compressed-air grid, or (4) ordinary sprinkling filters. The two first named aërating devices will here be briefly described, and the third and fourth will be taken up under Sprinkling Filters.

Aërating Siphon—This was adapted from a design used on a working scale, but under unfavorable conditions, at Millville and at Riverside, N. J. It is an application to sewage of the siphon air compressor, proposed by the late C. C. Beddoes, who obtained a patent covering the use of the siphon for sewage aëration, and the process. It may be operated with raw sewage or Imhoff effluent.

The flow of sewage is led by gravity to the bell, or enlargement at the top of the siphon pipe, into which the sewage falls, sucking the air in with it, and passing vertically downward with considerable velocity to such a depth that the entrained air becomes compressed, and the sewage exposed to it absorbs a greater proportion of air in consequence of the pressure: as the volume of air absorbed will be in proportion to the head or height of the volume above it.

The apparatus consists of a 4-in. pipe, extending vertically downward 130 ft., first through the center of a vertical tank, specially designed for this experiment, 30 ft. deep and 4 ft. in internal diameter, which rests on piles. The remaining 100 ft. of the 4-in. pipe passes downward inside of an 8-in. pipe, from the bottom of the 4-ft. diameter tank to below the bottom of the 4-in. pipe, which it inclosed. This leaves an annular space, through which the sewage returns from the bottom of the 4-in. pipe to the vertical tank, in which the sewage is retained for a period of time in proportion to the quantity of flow and capacity of the tank. The sewage leaves near the top of the vertical tank by means of a waste pipe and measuring-orifice box, from which a portion of the flow is piped for observation to one of the four secondary settling tanks.

Aërating Tank—This tank was developed from experiments made at the 26th Ward sewage works in 1911 by Col. Wm. M. Black and Prof. Earle B. Phelps. The tank is 12 ft. in diameter and 25 ft. 8 in. in height. The sewage enters at the top of the tank by gravity from the quieting tank, or the Imhoff tank, as the case may be, through a pipe surrounding the top. The sewage may fill the tank so that the points of entrance are submerged, or the tank may be operated at lesser depths of content. The tank effluent is taken off at the bottom.

A grid for supplying compressed air is placed on the bottom of the tank, 7½ in. of broken stone passing a 2-in. ring and retained by a 1-in. ring being provided to support it, and the same depth of broken stone being placed over it. The grid consists of two 1½-in. pipes at right angles, forming a cross connected in the center, the arms of the cross being connected with quarter circles of ¾-in. pipe forming concentric rings, of which there are five. Each ring is perforated at 6-in. intervals with $\frac{1}{16}$-in. holes. The air enters through the 1½-in. pipes and is distributed thereby to the rings and is discharged into the broken stone surrounding the grid, which tends to break up any upward streaming effect. The main outlets for the tank effluent are 1 ft. above this grid. Through the central axis of the tank is placed a vertical 4-in. pipe, which serves to center and support the deflector disks, of which there are nine, placed longitudinally, provided for the purpose of deflecting the downward flow of sewage and upward flow of air bubbles, so as to obtain even distribution of both air and sewage.

The deflectors are designed in the form of a wheel with a hub, which is of iron. Six radial arms are provided, between which slats are placed. The slats are set in grooves in the arms at an angle of about 45° with the horizontal; the slats in each alternate deflector being set at angles alternating from and toward the center.

Ordinary and Extra-Aërated Sprinkling Filters

Much of the interest in the plant centers in two sets of sprinkling or percolating filters, one set of four beds being of the ordinary type and the other set of two beds being equipped with a compressed-air aërating device, so arranged that one bed may be tested with and one without special aëration at the same time. Before the sewage reaches the filters, it may be passed through a gravel roughing filter and must pass through dosing tanks. The filters may be supplied with: (1) Crude sewage from the quieting tank; (2) aërated sewage from the siphon aërator; (3) aërated sewage from the aërating tank; (4) Imhoff-tank effluent; (5) any of the foregoing after having been passed through the gravel-roughing filter; (6) sewage passed through the Reinsch-Wurl screens. All the sewage is applied by gravity, except that from the screens, which will have to be pumped. The screens referred to are not yet installed.

Gravel Roughing Filter—This is a 12-in. bed of gravel passing a ¾-in. ring and retained on a ½-in. ring, supported on a wire screen of ¼-in. mesh.

Dosing Tanks—There is a dosing tank for each filter, equipped with calibrated orifices and constant-head overflow. Each dosing tank is also equipped with counters that record the number of discharges. The dosing tanks discharge into pyramidal feeding tanks.

The elevation of the water line in the dosing tanks at the instant of siphon discharge is 26.74 ft., which is 9.40 ft. above the surface of the filter beds. The elevation of the same line in the reversed pyramidal feeding tanks is 23.5 ft., which is 6 ft. 2 in. above the beds.

Ordinary Sprinkling Filters—There are four of these, square in plan, and each 0.005 acre in effective area, separated by 4-in. wooden partition walls and inclosed outwardly by reinforced-concrete piers, cast with slots for receiving 3-in. wood shutters sloping inward at an angle of 45°. The piers carry a reinforced-concrete coping, level with the top of the filter bed. The beds have concrete floors, on which rest 6-in. half-tile underdrains, convex side up. The filter medium consists of 10 ft. of broken trap rock. The size of stone in each bed is different, as follows: No. 1, passed a 1½-in. ring and retained on a ¾-in. ring; No. 2, 2 to 1 in.; No. 3, 2½ to 1¼ in.; No. 4, 2½ to 1¾ in. Provision is made for taking samples at depths of 6, 7¼, 8½ and 10 ft.

Extra-Aërated Sprinkling Filters—A tank 12 ft. in diameter and 16 ft. high is divided vertically into two equal parts, alike in every respect, with independent 6-in. half-tile underdrainage systems, resting on concrete. The beds are filled to a depth of 10 ft. with 2½ to 1¼-in. stone. This depth may be increased to 11 ft. if desired. Each bed is provided with a grid near its bottom, formed of ¾-in. iron pipe, perforated every 6 in. with ⅛-in. holes, through which metered compressed air is supplied. As already stated, one bed is operated with, and the other without, extra aëration, for comparative purposes.

SPRINKLER NOZZLES.—Various types of these will be tried. The initial installation is of the Taylor type. A board laid around and between each bed of each set serves as a wind shield to prevent unequal distribution.

SECONDARY SETTLING TANKS.—The secondary settling tanks provided for these filters are six in number, placed in a group, each tank being a reversed truncated pyramid 10 ft. deep from the water line. The flow enters through a 2-in. pipe carried down to a point 2 ft. above the bottom. A 6-in. sludge pipe acts under the hydraulic head of the tank. The tank effluent is taken off by means of troughs passing entirely around the top of each tank, two V-shaped openings being provided on each side of each tank. The effluent passes to the main sewer. The sludge removed may be studied upon drying beds.

The experimental plant was designed and constructed and is operated by the Bureau of Sewers, Brooklyn Borough, New York City. E. J. Fort is Chief Engineer of the Bureau of Sewers.

The Salem Water-Works and the Salem Fire*

BY FRANK A. MCINNES† AND CLARENCE GOLDSMITH‡

The point of origin of the Salem fire (June 25, 1914) on Boston St., between Pope and Proctor streets, was immediately adjacent to a 20-in. main having a normal pressure of a little more than 50 lb. The building in which the fire started, and those surrounding it, were of frame construction and mutually exposed each other, thus enabling the fire to spread with such rapidity that the adjoining buildings were almost immediately involved. Two of these were protected by automatic sprinklers. Before the first hour had lapsed, 10 engines were at work, and a conservative estimate based on a careful study of lengths of hose lines, sizes of nozzles, and water pressures maintained at the engines, shows that at no time during this period was more than 2500 gal. of water per min. pumped from the distribution system, yet the recording pressure gage maintained by the Water Department on Church St. registered a drop in pressure from its normal of 42 lb. to 20 lb. at the end of the hour.

At the beginning of the fire the 30,000,000-gal. reservoir was practically full, the two 5,000,000-gal. pumping engines were in operation under a full head of steam, the 30-in. and 20-in. supply mains were in service. No breaks occurred in the street mains during the progress of the fire.

A test of the carrying capacity of the distribution system was made on Aug. [illegible], 1914, as follows:

[illegible] were set on hydrants near the point of origin of the fire. These hydrants were opened, two discharging through three 2½-in. outlets and two through four 2½-in. outlets. In addition, a post hydrant in an adjacent alley was discharging through two 2½-in. outlets. The flow from each of the [illegible] outlets was measured by Pitot tubes and showed a total of [illegible] gal. per min. The drop in pressure in the 20-in. main at the point where the test was made was observed on the pressure gage attached to a hydrant which was not discharging. The gage showed a pressure of 54 lb. prior to opening the hydrants and 22 lb. while they were discharging, giving a drop of 32 lb. The recording gage on Church St. showed a pressure of 47 lb. before the test and a pressure of 27 lb. while the hydrants were discharging. The quantity of water obtained shows an abundant supply at this point, an amount in excess of the combined capacity of the engines working at the end of the first hour.

A draft from the mains equal to the previously estimated quantity pumped by the engines, namely, 2500 gal. per min., would cause a local drop in pressure of less than 4 lb. On the date of the fire, the recording gage on Church St. showed 42 lb. pressure when the first alarm was received. In 30 minutes the pressure had dropped to 33 lb., and at the end of the hour to 20 lb.

From this record it is evident that a quantity of water approximately equal to the quantity obtained at the flow test was being withdrawn from the system and the principal object of the investigation here recorded was to account for this large rate of flow. The 8-in. and two 6-in. connections supplying the two sprinkler risks already referred to must bear the blame. The 8-in. connection from the 20-in. main was through 25 ft. of pipe to the sprinkler equipment in the Charles H. Kettle plant. The two 6-in. connections supplying the sprinkler equipment in the Carr Leather Co.'s plant was fed through 200 ft. of 8-in. main connected to the 20-in. pipe. These buildings ignited immediately and a large number of sprinkler heads opened in a very short time but were powerless to check the fire. The collapse of the buildings resulted in the breaking of the sprinkler pipes, allowing the capacity of the three large connections to be wasted from the 20-in. main. To determine the actual effect of these three broken pipes they were opened shortly after the flow test above referred to was made, with the following result:

A gage on a hydrant on the 20-in. main showed a normal pressure of 54 lb., and when the connections were open and flowing, a pressure of 31 lb., which, from the previous flow test, enabled the discharge from these pipes to be accurately determined at 3200 gal. per min., a quantity of water in excess of the entire supply required for the fire protection of a city the size of Salem according to the best modern practice. The Church St. gage fell during this test from 46 to 35 lb. The effect of these broken connections is further evidenced by the record of this gage which continued to drop during the fire until it registered 15 lb. about 3 p.m., at which time a supply at the rate of 8,000,000 gal. per day was obtained from the Peabody system without improving the pressure. At about [illegible] o'clock, the [illegible] so that these connections, together with a post hydrant, which had been discharging through two 2½-in. outlets, were closed and the pressure immediately rose to a little over 21 lb. in spite of the fact that many service pipes were broken at this time.

The lesson to be learned from the experience in Salem is that the existence of connections from a distribution system of such size that their failure destroys the pressure at the hydrant is a mistake that surely invites disaster to a water-works system and [illegible].

The record of fires occurring in sprinkler risks during the past 18 years shows that in a total of 11,359 fires

*[illegible]

†[illegible]

‡[illegible]

13,691 were controlled by the opening of less than 51 sprinklers, and only 662, or 4.6%, were not controlled by this number of sprinklers, which number can be supplied by a 4-in. connection.

In most closely built-up sections the first piece of apparatus will be on the ground within three minutes of the alarm of fire and additional water may be immediately delivered to the sprinklers through outside siamese connections with which all sprinkler equipments should be provided. The fire department would then have the supply under its control and be able to deliver the water at the seat of the fire rather than use it with little effect, as is so often done. Such a method of operation would preclude the possibility of a single large connection menacing the entire community.

Some Notes on Street Cleaning

Among the many papers read last week before the annual convention of the American Society of Municipal Improvements, at Boston, Mass., there was one on street cleaning in general and a second, a very brief one on special practice with one kind of pavement at Providence. Those portions of the former having to do with machine cleaning are presented below in condensed form, and here is also given the substance of the notes from Providence.

Machine Street Cleaning

By Edward D. Very*

New York has 2173 miles of paved streets, Chicago 1899, Philadelphia 1371, and the other large cities have from 100 to 500 miles. Under average conditions a man can hand clean but about one-half mile per day. Even could he perform the work with thoroughness, the cost of such an army of labor for this work would be prohibitive. Machines at present used can do from two to four miles each and this work is done with a good degree of thoroughness, making daily work on the same area unnecessary. The patrol man then merely polices the streets as a litter gatherer and can cover a very considerably larger route.

The machine broom as today operated leaves much to be desired; purely, I think, because the action of the broom is dependent upon the speed of traction, whereas should a motor vehicle be substituted, power may be transmitted to the axis of the broom independent of the tractive power of the machine, a proper rate of revolution of the broom may be found and maintained irrespective of the speed of progress of the machine. At present if you find a particular filthy spot and endeavor to slow up to give it more careful attention, the speed of the broom lessens and the effect is loss, whereas were the power independent the result would be that required.

A mechanical device attached to the sweeping machine to pick up the stroke of sweepings from the broom and empty into a receptacle or receptacles would avoid a considerable amount of extra work now performed because the materials are spread by the wind or tracked by vehicle tires. Such machines are in evolution now but most of the devices are complicated or otherwise ill adapted to the performance of this work.

Flushing machines and squeegees are now constructed which do effective work but their adoption has been greatly retarded by the claims that the water has an adverse effect upon paving materials. My judgment is that the paving engineer should design his exposed surfaces to resist water action for the great benefit to be derived from water cleansing. In flushing machines there is a distinct advantage in having an attached pump to press the water so as to get a positive action continuously and on all the water which the storage tank may carry. A motor flushing machine has the advantage of carrying larger quantities of water with a consequent conservation of the time now lost in frequent filling of small tanks.

The machine squeegee or rubber scrubber is effective on smooth pavements where not too filthy, but the present method of delivery of water so close to the scrubber renders the work imperfect through the ineffective action of the water on the filth before the scrubbing is applied. This may be remedied by preceding the squeegee machines by a sprinkling cart sufficiently in advance to give the water action full effect. And here let me say that the sprinkling wagon should not be used, in my opinion, except as an adjunct to other cleansing devices, as by itself it is but a temporary makeshift and ineffective for good result. There is no reason for the filth removed by washing machines being deposited in sewer basins. The machine should be so operated as to leave the dirt near the curb, to be picked and carted away, as soon as it becomes sufficiently dry.

Dry-cleaning machines are greatly to be desired and good progress is being made in the development of such. I know of two types of vacuum cleaners which are doing good work and need but little to make them practical and effective. These, of course, should be designed to pick up and place in receptacles the filth removed. When dry cleaning machine work is adopted there must still be periodical wet cleaning and such a combination should insure the best results.

*Sanitary Engineer, 17 Battery Place, New York City; formerly of the New York Street Cleaning Department.

Clean Bituminous Pavements without Sprinkling

By Walter F. Slade*

In Providence we keep bituminous pavements clean by the patrol system, and reasonably free from dust. We believe that the use of water has an injurious effect upon the durability of the pavement. It emphasizes every slight depression and gathers and retains the fine particles that collect on a street, creating an unsightly appearance and a muddy, slippery condition. This results in the skidding of automobiles and a vast increase in the number of accidents.

By keeping the pavements free from water we escape another prolific source of complaint. Upon the best of pavements there will be depressions sufficient to retain a thin sheet of water. The rubber tires of the swiftly-moving auto, and especially the auto truck, will force the muddy water in a small stream upon the clothing of any one passing along the sidewalk, and even across the sidewalk, covering windows and buildings with muddy spots.

The Garbage of St. Louis is being dumped into the Mississippi River below the city. The Indiana Reduction Co. has a five-year contract for the treatment of the garbage but its plant was closed in July on account of objectionable odors. Another company has taken over the plant and will reopen it shortly, but the city is said to be planning to build its own garbage-reduction plant.

*Commissioner of Public Works, Providence, R. I.

Field and Office

Reinforcing the Winona Bridge, C. & N. W. Ry.

The Chicago & Northwestern Ry. crosses the Mississippi River at Winona, Minn., by a long bridge consisting of a series of through-truss spans. The bridge consists of 16 spans, with design and loading as follows:

(A) Twelve riveted lattice through-truss spans, built in 1891: five of 159 ft. 8 in., six of 142 ft. 2 in. and one (shore) of 104 ft. 6 in. Designed for a load of 3000 lb.

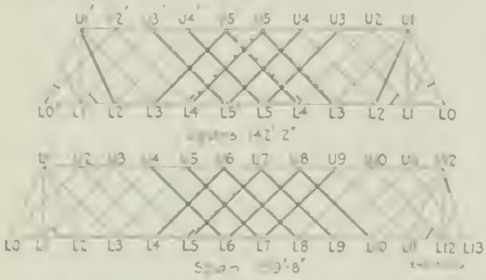

Fig. 1. Riveted Lattice Trusses of the Winona Bridge; C. & N. W. Ry.

(The heavy lines show the reinforcement.)

per lin.ft. with engine excess of 10,000 lb. Iron in tension, 8000 lb.; in compression, 8000 lb. for 159-ft. spans and 7000 lb. for shorter spans, reduced by Gordon's formula.

(B) Two pin-connected through-truss spans of 2[illegible] ft., built in 1895. Live-load, two 107-ton engines (2-8-0) followed by train load of 3000 lb. per lin.ft. Iron in tension, 10,000 lb. live-load, 20,000 lb. dead-load; in compression, 7500 and 15,000 lb.

(C) One pin-connected draw span of 456 ft., built in 1898. Live-load, two 141½-ton engines (2-8-0) followed by 4000 lb. per lin.ft. Iron in tension, 9000 lb. for riveted members and 11,000 lb. for eye-bars; in compression, 8000 lb. reduced by Gordon's formula.

(D) One deck plate-girder span of 85 ft., built in 1898 for the same loading as the draw span.

With the increase in weight of locomotives and trains it became necessary to strengthen the 12 lattice spans to adapt them to the new conditions, and these spans have been reinforced to carry two 202-ton locomotives (2-8-0) followed by 4000 lb. per lin.ft. of train load. The other four spans, being designed for much heavier loading than the older lattice spans, and with low unit stresses, were found not stressed to excess by the modern engine loading.

A careful study was made of the composition and stresses in each span, and the reinforcement designed accordingly. This consisted mainly of additions to the web members of the trusses and the floor members of the riveted spans.

The trusses, Fig. 1, have some web members composed of only a pair of angles, and the principal reinforcement consisted in applying two additional angles to each overstressed member, attaching these to the original angles with tie plates. Additional connections to the chords were applied also, and in some cases struts were fitted to connect the end post with the first web member

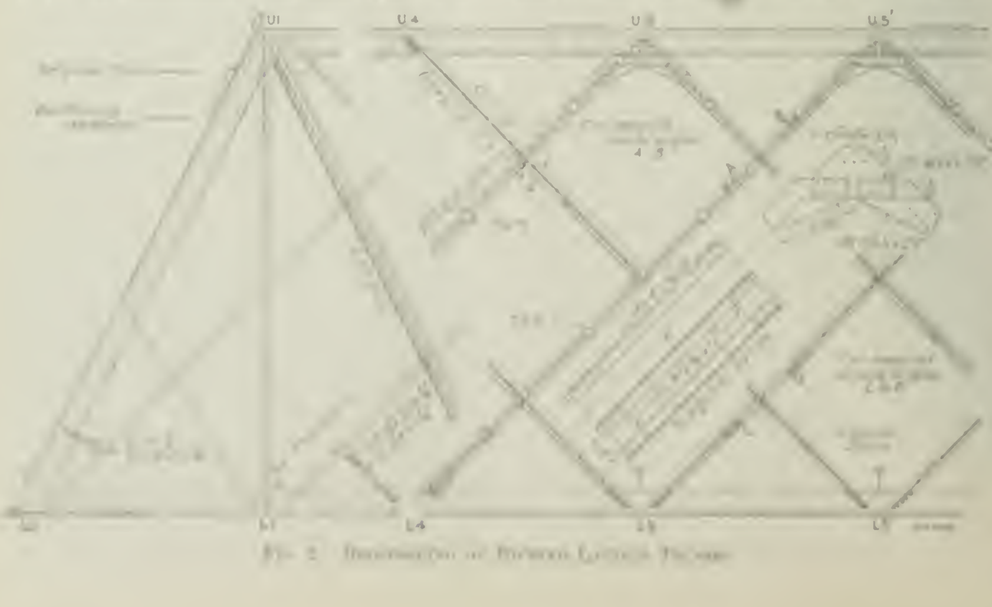

Fig. 2. Reinforcement of Riveted Lattice Trusses

Fig. 1 shows the general design and the location of the reinforcement, while Fig. 2 shows further details of the work on the trusses.

In planning the reinforcement of the floor-beams, it was recognized that to strengthen them by adding cover-plates and other riveted work would be very expensive.

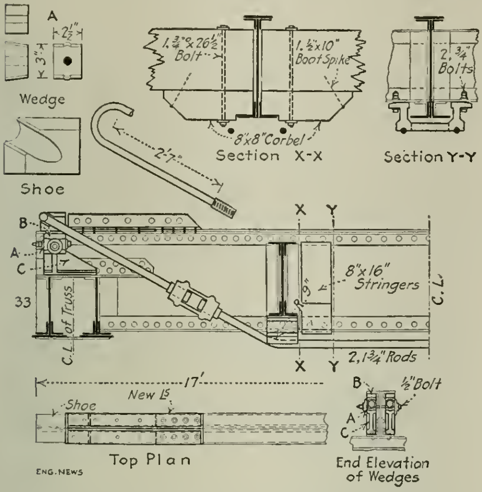

Fig. 3. Reinforcement of Floor-Beams by Truss Rods; Winona Bridge, C. & N. W. Ry.

A method of securing the necessary additional strength by means of tie-rods was devised, therefore, and special aim was made to reduce to the minimum the amount of field drilling required for applying these rods. To reinforce the stringers and floor system a line of 8x16-in. fir stringers is placed inside of each of the original track stringers, their ends resting on corbels fitted to the bottom flange angles of the floor-beams.

The floor-beam reinforcement is shown in Fig. 3, and consists of a pair of 1¾-in. truss rods to each beam. Their ends are attached by turnbuckles to the legs of stirrups whose loop ends rest on shoes riveted to the top of the floor-beam at each end. The truss rods pass under cast-steel saddles located at the bottom flange of the floor-beam but bearing against the bottom flanges of the steel stringers. The bearings of the floor-beams on the trusses were strengthened by means of a set of cast wedges placed between the top and bottom angles of the floor-beams and driven to a bearing by means of a bolt. The device consists of the two opposite wedge pieces (A) between the cap (B) and pedestal (C). This arrangement was found to be much more economical and much more effective than riveting on short end stiffeners.

The method of carrying on the work under traffic was not difficult, as there was no occasion to obstruct the tracks, and the reinforcing of the trusses consisted only in light members which were easily hoisted into place. A gasoline air-compressor plant was installed at the east end of the bridge, and air pipes were carried on the floor to the various spans.

The work was done by the railway company's bridge department during 1913 and 1914. It was designed and executed under the direction of W. C. Armstrong, Engineer of Bridges, Chicago & Northwestern Ry., to whom we are indebted for our information.

Pile-Testing as Practiced with "Pedestal" Piles

Further discussion of the proper way to carry on a pile test or a soil bearing test* is contained in the following description of the MacArthur Concrete Pile & Foundation Co.'s practice in testing "Pedestal" piles (concrete piles with enlarged foot, formed in the ground). The so called pile formulas which are used for guessing at the capacity of a driven pile are altogether useless in the case of Pedestal piles, and therefore pile tests became almost indispensable. Hunley Abbott, chief engineer of the company, says that over 100 such pile tests have been made up to the present, and that, as these furnish experience and figures for almost every conceivable soil condition, tests are now not made usually except where the owner wishes them for his own satisfaction.

In preparing for a test the top of the pile is cleaned off and a concrete cap molded on it (see drawing, Fig. 1 herewith), the pile projecting a few inches into the cap. A steel bolt molded in the top of the cap furnishes a footing point for the leveling rod in measuring settlement.

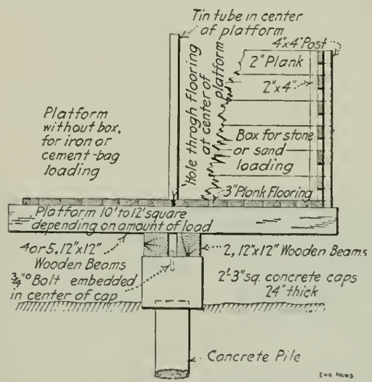

Fig. 1. Sketch of Pile-Testing Rig Used in Tests of Pedestal Piles

On the cap is built up a platform composed of two tiers of 12x12 grillage covered with a 3-in. plank floor. If the loading material is sand or broken stone, a box must be built on the platform, but for pig iron or cement in sacks the simple platform will do. A tin tube passing through a hole in the middle of the floor enables the leveling rod to reach the bolt in the pile top.

Blocking near the ends of the 12x12 timbers keeps the platform from tipping while the load is being placed; but by the time the full load is on the load should have been brought to a balance, so that the blocking can be removed.

A level reading on the bolt should be taken before any weight is placed on the platform. Further readings

*For previous data on these two subjects see May 7, 1914, p. 1024 (Erie R.R.); July 23, 1914, p. 203; July 30, 1914, p. 250 (Panama-Pacific); Aug. 6, 1914, p. 310 (Pittsburgh); Sept. 3, 1914, p. 510; Sept. 24, 1914, p. 647; Oct. 1, 1914, p. 704 (Michigan Central).

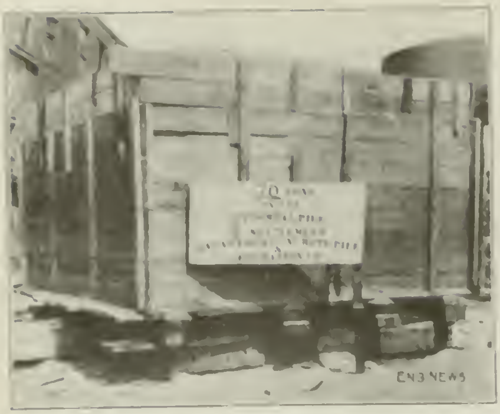

FIG. 2. A 70-TON TEST LOAD ON A PEDESTAL PILE FOR A GAS-HOLDER FOUNDATION, NEW BEDFORD, MASS.

should be taken at various stages of the loading and a final reading when the load is all on. The total load should be allowed to remain on for several hours and readings taken to ascertain whether any further settlement occurs. Mr. Abbott's experience indicates that if the pile shows any settling tendency at all after receiving the final load, this tendency is relatively small, and the pile will come to a complete stop in a very few hours after ending the application of the load (24 hr. ample in all cases).

Pedestal-base piles should be allowed at least three weeks for curing of the concrete before load is placed on the pile, even under the most favorable conditions; better four weeks.

Fig. 2 shows a test made according to the procedure above described on a Pedestal pile installed for the foundations of a large gas-holder at New Bedford, Mass. The test pile was chosen at random by the engineers and all level readings were taken by them. No settlement was observed up to 40 tons loading; from 40 to 70 tons a small settlement developed, the total at 70 tons being less than [illegible] in. after the load had been on for 24 hr.

Another interesting series of tests was made on Pedestal piles for the foundations of the Canadian Vickers plant at Montreal. Out of 2000 piles driven for the works, 19 were tested. Each was loaded to 42 tons standing for 24 hr. The total settlement ranged from [illegible] to a scant ¼ in. In this case the loading was done with pig iron on a flat platform. In testing four piles in the foundations of the Subtreasury building, San Francisco, Calif., the maximum loading was 72 tons. No settlement was observed. These piles were tested with a cement-bag loading on a platform (without box).

Lining Large Coal Bunkers by the Cement-Gun Process

The new plant of the Minnesota Steel Co. at Duluth, Minn., has 53 coal bunkers for the gas-producers and a large circular storage bin for the coke ovens. It was decided to line these with cement mortar for protection against rusting. The lining was applied by the cement-gun process. It was intended originally to use a 6-in. lining of concrete placed by hand, but the cement-gun work was not only done at greatly reduced cost, but it also gave a lining of greater density and (owing to the impelling force) it insured closer contact and adhesion with the steel.

FIG. 3. LINING A [illegible] COAL TANK WITH CONCRETE BY THE CEMENT-GUN PROCESS

([illegible])

FIG. 4. LINING A COAL BUNKER BY THE CEMENT-GUN PROCESS

([illegible])

The coal-storage bin which serves the coke ovens is 55 ft. diameter and 40 ft. high, with a capacity of 2100 tons, and is supported on a framing of steel girders and columns. It is fed at the top by a conveyor, while the coal is drawn off at the bottom by 20 hoppers 7 ft. square and 9 ft. deep, through which the coal is delivered to the charging cars. The capacity is equal to about one day's supply, so that the coal in the tank is practically in continual motion.

To the steel shell were riveted Z-bar lugs to which were fastened ½-in. vertical rods, and to these was wired a layer of triangular-mesh wire netting, about ¾ in. from the shell. The mortar is a 1:4 mixture of cement and sand; the dry mixture, forced through hose by the cement-gun, receives the mixing water at the nozzle from a separate pipe. In the impact upon the steel a portion of the sand is liberated, so that the actual mixture as placed is about 1:3½. The air-pressure in the cement-

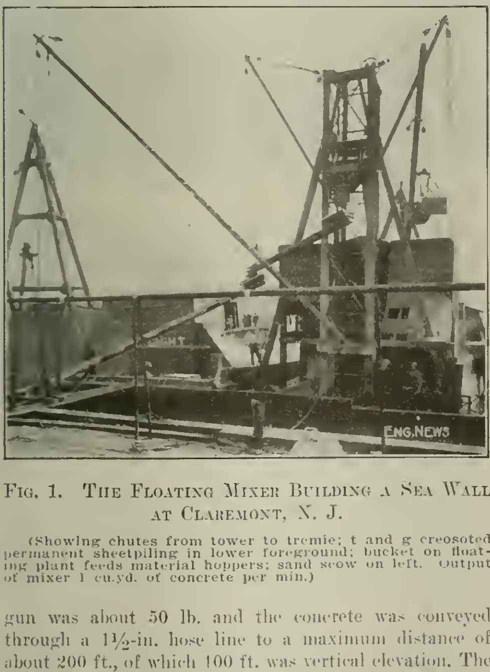

Fig. 1. The Floating Mixer Building a Sea Wall at Claremont, N. J.

(Showing chutes from tower to tremie; t and g creosoted permanent sheetpiling in lower foreground; bucket on floating plant feeds material hoppers; sand scow on left. Output of mixer 1 cu.yd. of concrete per min.)

gun was about 50 lb. and the concrete was conveyed through a 1½-in. hose line to a maximum distance of about 200 ft., of which 100 ft. was vertical elevation. The concrete was applied in two coats, the first or stiffener coat filling behind the reinforcement and the second forming the finish. The total thickness is 5 in.

The working crew consisted of a foreman and nine men, three of the men working on the scaffold in the tank; as shown in Fig. 1. The work occupied about six weeks working time for the application of the reinforcement and the lining.

The same lining, but with a thickness of only 2 in., was used for the 33 parabolic bins serving the gas producers. These bins are 19 ft. square and 12 ft. deep. Fig. 2 shows the work being done in one of these bins.

The work was executed under the direction of K. C. Hoxie, Chief Engineer of the Minnesota Steel Co. The Cement-Gun Construction Co., of Chicago, had the contract for the work of lining all the bins and bunkers.

Building a Concrete Sea Wall with a Special Floating Mixer

A rock-filled crib bulkhead at the Standard Oil Co.'s Eagle Works at Claremont, N. J., is being reinforced, practically replaced, by the construction of a heavy concrete wall in front. The crib is about 20 years old and has deteriorated to such an extent that the rocks were falling out at the face. The bulkhead is about 700 ft. long by 23 ft. high. The concrete wall, 10 ft. thick, was placed in water, by means of a tremie. A specially laid-out floating concrete-mixing plant was used.

Floating Concrete-Mixing Plant

A concreting tower was erected on a scow, with mixer adjoining and arranged so that the concrete moved by gravity into the 1-cu.yd. hoisting bucket, as shown in

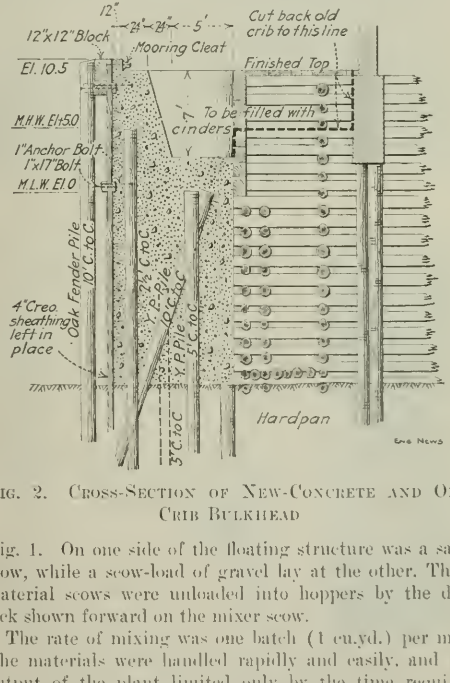

Fig. 2. Cross-Section of New-Concrete and Old-Crib Bulkhead

Fig. 1. On one side of the floating structure was a sand scow, while a scow-load of gravel lay at the other. These material scows were unloaded into hoppers by the derrick shown forward on the mixer scow.

The rate of mixing was one batch (1 cu.yd.) per min. The materials were handled rapidly and easily, and the output of the plant limited only by the time required to mix. The first two lengths of chute were supported by booms extending from the tower. The third length was held by an A-frame placed on the new wall. The concrete passed from the chute into a hopper which fed the tremie. A pump supplied salt water for the mixer.

Method of Procedure

The site was first dredged to hard bottom, about 15 ft. below low water. Bearing and brace piles, 35 ft. long, were driven and cut off at low water. A line of 4-in. t & g creosoted sheetpiling to serve as face form was then put down, and the concrete deposited. The work was carried on in 100-ft. sections, one section being completed before another was commenced, so that the finished portion was available for commercial use.

The concrete was carried up full width to half-tide level (2 ft. 6 in. above low water) and above this the rear face battered as shown in Fig. 2. A 12x12-in. concrete backing log was placed along the top of the wall and provided with cleats for tying up boats. The timber crib was cut off 5 ft. from the top, and the space thus made as well as that back of the curb wall, filled with cinders. A plank floor was then laid over both the wall and the crib.

The creosoted sheetpiling will be left in place to protect the concrete against deterioration from tide action and temperature variations.

The work is being done by Geo. B. Spearin, 90 West St., New York City.

Calibrated Orifices at the Brooklyn Sewage-Experiment Station

By Geo. T. Hammond*

A considerable number of graduated adjustable orifices are being used to control the flow to the settling tanks, filters and other elements of the experimental

Fig. 1. View of Orifice

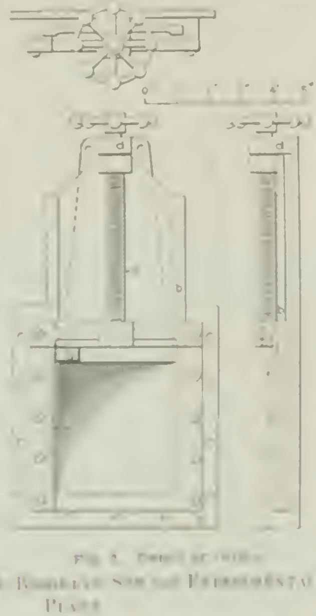

Fig. 2. Detail of Orifice

Calibrated Orifice, Brooklyn Sewage Experimental Plant

sewage-treatment plant at the 26th Ward pumping station, Brooklyn, N. Y. Before installation, each orifice was calibrated in place by actual measurement of the discharge from one of the large tanks at the experiment plant.

The sewage at the experiment station is first pumped to a receiving tank and is then passed through one or the other of two orifices to a flume leading to a tank of the plant. When the effluent from one of these units receives further treatment it is again passed through an orifice, placed in an orifice box, to control the rate of flow.

The orifices were supplied, installed and calibrated by the Wallace & Tiernan Co., Inc., of 136 Liberty St., New York City. The smallest of the orifices called for by the specifications was required to measure flows ranging up to 150,000 gal. per 24 hr. and the largest up to 600,000 gal.

Fig. 1 shows one of the orifices in use and Fig. 2 shows one in detail. In the drawing a is a back plate, screwed to the outside of the constant-level box; b is a sliding gate moved by screw c, which turns in the threaded part d. The scale e is made by obtaining points by actual measurements of the sewage discharged through the orifice at different openings into the tanks of the plant; several points on the scale were thus obtained and the others interpolated.

The orifices are of bronze. All sliding parts are machined so as to work easily and yet fit tightly. They are made according to the principle of hydraulic discharge; but the discharge as actually measured varied somewhat, owing probably to the velocity of approach through the 2-in. planking of the wall of the constant-level boxes on the outside of which they are placed.

E. J. Fort is Chief Engineer of the Brooklyn Bureau of Sewers.

*Engineer in Charge, Bureau of Sewers, 215 Montague St., Brooklyn, N. Y.

Oil-Engine Excavator with Detachable Tractor

The Turner Excavator, used in the emergency ditching job described on p. 711 of the Oct. 8 issue of Engineering News, is a strikingly new type of machine. The excavator and tractor parts are made separate, each with two wheels, their frames being coupled together somewhat like the coupling of motor-truck tractors and trailers. Moreover, the forward part of the machine, i.e., the excavator portion, can be coupled up with any other tractor or traction engine. The machine is built by the United Iron Works Co., Springfield, Mo.

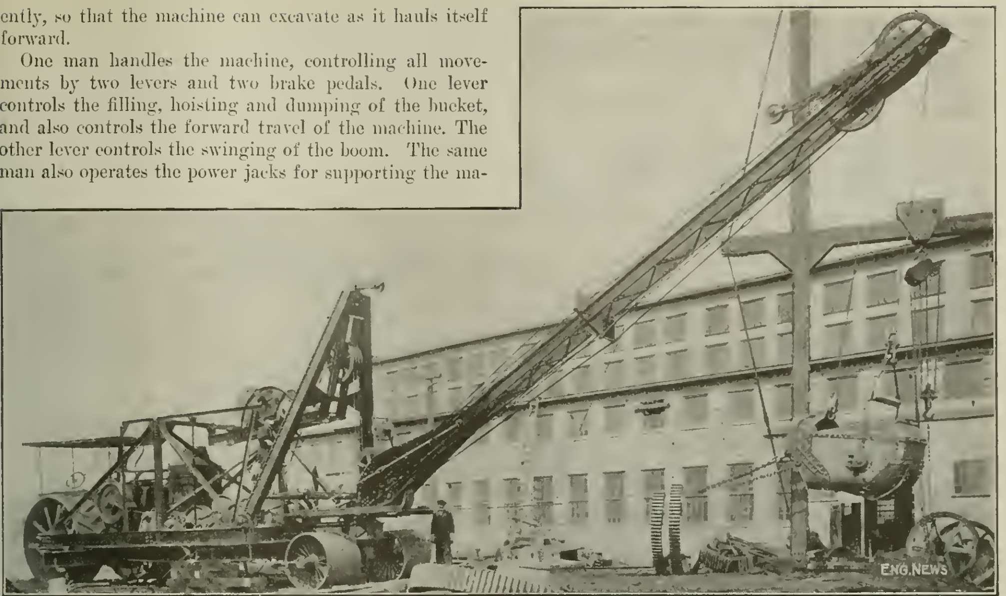
The machine is primarily a drag-line machine, but it can be converted into a steam shovel by some changes: replacing the long boom (see view) by a shorter (dustergirder) boom with dipper handle and bucket.

The excavator machinery is mounted on a trussed-steel frame, with a pair of wide-tread wheels under the front end. The rear end of the frame is forked, and embraces the forward part of the tractor, the latter resting upon a crossframe of the frame. The sills extend back far enough to form outboard bearings for extension hubs which are bolted to the centers of the rear (driving) wheels. In adapting the excavator to an existing tractor, the front axle and wheels of the latter are removed and its front end is supported on and attached to the crossframe, as noted above. Any kind of tractor may be used (steam, oil or gasoline) and any kind of grab or scraper bucket can be handled.

The machine shown in the cut is 28 ft. long, with 40-ft. boom, 1½-yd. scraper bucket, an A-frame 15 ft. 6 in. high, and front wheels 18 in. diameter. It is driven by a 60-hp. oil tractor and weighs complete about 10 tons. In addition to the propelling gear it has a rudder-steering drum which enables the machine to be steered readily over wet ground. The towing rig is driven independ-

ently, so that the machine can excavate as it hauls itself forward.

One man handles the machine, controlling all movements by two levers and two brake pedals. One lever controls the filling, hoisting and dumping of the bucket, and also controls the forward travel of the machine. The other lever controls the swinging of the boom. The same man also operates the power jacks for supporting the machine on either side, and shifts the platform tracks used on soft ground. These platforms are 18 ft. long, and much wider than the wheels.



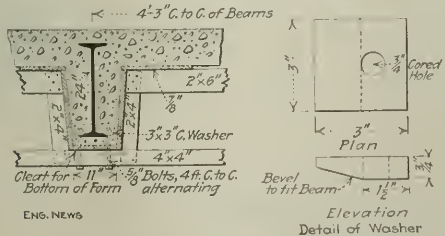
Drag-Line Excavator Operated by an Oil Tractor of 60 Hp.
(Union Iron Works Co., Springfield, Mo., builders.)

NOTES

A Beveled Washer as the main detail of a form support for forms for placing concrete incasement around steel beams was used by Peters & Kiehm, the contractors for the Pleasant St. viaduct of the Delaware, Lackawanna & Western R.R. at Utica, N. Y. The detail of the construction is given in the accompanying cut. This part of the bridge consisted of 24-in. longitudinal I-beams spaced 4 ft. 3 in. center to center, completely incased with 2 in. of concrete and carrying the roadway on a reinforced-concrete superposed slab.

The form consisted of 4x4-in. stringers hung 1 ft. on center from the lower flange of the main I-beam, carrying the concrete form as shown in the drawing.

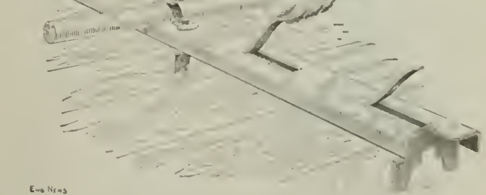
The hanger bolts had their head at the lower end and were hung from the lower flanges of the I-beam by specially made washers beveled as shown in the detail on the drawing to fit the lower flange of the beam. In erection, the 4x4-in. sticks were hung on one set of bolts, from one flange of the beam, and the bottom of the beam box placed on the opposite side, the bolts being put through holes bored for that purpose. Then the first placed bolts were removed, allowing the beam box to be hung by the second set of holts, while the first line of hanger bolts was replaced and the beam box sides and floor forms were set.



Beveled Washers to Carry Beam Box for Concrete Incasement

The bolts and nuts were well greased and after the concrete was placed the forms were taken down by unscrewing the heads of the bolts, leaving the washers and the nuts in the concrete; the holes in the concrete were plugged up with cement mortar.

A Patented Spacing Bar for holding and spacing reinforcing rods in concrete slabs has just been put on the market by the Electric Welding Co., of Pittsburgh, Penn. The accompanying sketch gives a view of the bar and the method of its use. It is known as the "Efficiency Spacing Bar." The bar consists of a 3/4-in. channel pierced at proper intervals for floor rod spacing (say 3 or 4 in.) with openings the metal strip from which is bent up at an angle sufficient to admit the floor rod. At every other one of these openings a chair is welded so as to carry the spacing bar (and the reinforcing rods) the proper distance above the bottom of the slab. The floor rods are clamped solidly into place by a hammer blow, which easily bends the projecting metal strip tight over the rod.



"Efficiency Spacing Bar"

The section of the bar is about 3/8 sq.in. so that it serves also as a transverse stiffening or reinforcing rod.

Status of the Proposed International Congresses at San Francisco in 1915

The first positive action regarding the International Congresses, scheduled to be held in San Francisco next year during the Panama-Pacific Exposition, is the announcement that the Electrical Congress will be indefinitely postponed. The Executive Committee has been continued, its records preserved, and the bills will be settled by the American Institute of Electrical Engineers. It is intended to hold the congress eventually, and in America.

In view of the absolute impossibility of holding a truly international meeting, on account of the European War, this action is entirely wise. Those organizations which carry through their previous plans for holding congresses may possibly secure a fair American attendance, although even that is problematical in view of the decreased interest which will result from the scanty foreign representation, and because many American engineers will be deterred by business conditions from taking the time and money necessary to attend a congress at San Francisco next year.

Ethics and Compensation of Engineers Again

In our issue of May 7 last, we published a letter entitled, "Ethics and Compensation of Engineers from the Standpoint of a Lawyer." The second paragraph of this letter read as follows:

> An active writer on engineering ethics, prominent in the American Society of Civil Engineers, who would unquestionably consider it unethical for an engineer to guarantee or assume the financial responsibility for the commercial success of a new design in practice, had no scruples about reporting under his signature, on the same day, that the same railroad project would cost $17,000 per mile in his report to the promoting company, and $25,000 per mile in his report to the Provincial Ministry, for the purpose of securing a subsidy for the promoting company of $20,000 per mile.

The fact that no names were mentioned in the above quotation or in the letter of which it formed a part is probably the reason why it passed editorial scrutiny, although our scrutiny ought to have been particularly strict since the letter purported to be written by a lawyer! It is part of a lawyer's business to state facts in such a manner that they will produce a desired impression. Since the letter was published, statements have been laid before us which show that the statement above quoted was entirely unwarranted.

The papers in the case show that the engineer in question did present two different estimates of cost for a projected railroad, and in fact presented more than two different estimates; *but the different estimates were based on widely different specifications.* One estimate, for example, was based on entirely different requirements as to maximum grade and curvature, weight of rails, etc., from the other. It should be further stated that both reports were made to the promoting company, the engineer's client, and that no report was made to the Provincial Ministry, save that the engineer in question represented his client in negotiations over the railway project, which later became the subject of a bitter political controversy in the Provincial Parliament; and as those familiar with Canadian politics are aware, professional and personal and business reputations are often sacrificed to the necessities of partisan political squabbles.

In the present case, however, the papers submitted to us indicate that even the attorneys of the opposition conceded at the end that the action of the engineer in question was that of a high-minded professional man discharging his duty toward his client. It was very likely some distorted newspaper report of the squabbles in the Provincial Parliament which led to the unfounded accusation in our issue of May 7, referred to above.

We deem it worth while, even at this late date, to set forth the facts in this case in order that at least one unjust and unwarranted attack upon the honor of the engineering profession, as represented by one of its prominent members, may be rendered of no effect.

Military Engineering Training for the Engineering Student

We believe that engineers who were educated at a "land-grant" college generally look back upon their compulsory military training there (which is the federal government's compensation for financial assistance) as a period of drudgery. While the young male is essentially a military creature and the tin soldier a plaything *par excellence* to the boy, the soldier's life, or at least that part of a soldier's life which involves two hours' drill inside of a dusty and ill-ventilated armory, does not as a rule appeal to the more mature boy at college. However, an all-wise government considers that even this limited military experience is a desirable part of the education of young men; and furthermore it is constantly trying to make this enforced military drill somewhat more interesting to the students. It is worthy of note in this connection that special instruction is now being given in military engineering in some of the land-grant colleges.

Under the American system of army development, the United States must depend for its armed forces in time of war upon a small nucleus formed of the regular army, distributed as a leaven through the great mass of volunteer troops. In order that those who may have to make up this volunteer army should not be entirely ignorant of the work which they may be called upon to perform, certain of the youth of the country are trained in the elements of military science either in school, in college or in the National Guard. In the National Guard, there are sections devoted to the practice of military engineering, which perform the functions of the engineer-companies of the regular army. These sections, however, are much too small and the time given to their work much

not fitted to take up all of the duties which naturally devolve upon an engineer corps in time of war. In fact, in the Spanish-American War there were formed some volunteer engineer companies.

In the event of any extensive war, such companies must be formed and their efficiency will naturally be greater if they are made up of men whose ordinary occupation has to do with engineering. Yet while such civilian engineers are eminently more fitted for the practice of military engineering than would be a civilian who knew nothing of engineering, the entirely novel features of military engineering are so many as to require considerable time and labor on the part of a civilian engineer if he is to be capable of performing the work of his military brother.

It seems eminently fitting, therefore, that boys engaged in the study of civil engineering, who are required by the government to devote some time to military studies, should devote that time to the study of military engineering. Thus in the event of a war where their services would be required, they would be able to bring to the very important engineering corps of the army not only a training in civil engineering but some elementary knowledge, at least, of the military engineer's work. At the same time it adds to the student engineer's curriculum a study which should be much more interesting than the routine drilling of the infantry branch.

At Cornell University during the coming year an engineer corps is to be added to the student "army," and is to be not only under the direction of the U. S. Army officer who is in charge of military instruction there, but is also to have instruction by a retired sergeant of engineers of the U. S. Army, a man who can undoubtedly bring to the instruction of the student more practical experience than the line officer who is commandant.

The Design of the New York Barge Canal

We quoted in our issue of Aug. 27, 1914, a statement by John A. Bensel, State Engineer of New York, to the effect that a Western manufacturing concern which desired to use the New York Barge Canal when completed and investigated the relative cost of rail and water transportation found that for economical transportation freight should be shipped through without transfer. The ship designers, however, Mr. Bensel stated, have not yet been able to design a vessel which could navigate both the Lakes and the barge canal with the limited depth and overhead clearance prevailing on the canal.

This statement of Mr. Bensel's was discussed in a later issue (Sept. 10) by John Reid, the well known marine architect, and he raised the very natural question why the barge canal was not designed in the first place so that it would accommodate vessels capable of Lake navigation. Mr. Reid said:

It has always seemed extraordinary to naval architects and shipbuilders that all the efforts [illegible] made in designing the New York Barge Canal [illegible] Mr. Bensel in his statement declares that shipbuilders have found it [illegible] Canal [illegible] the Barge Canal engineers designed so as to be adapted for the passage of vessels which could navigate the Great Lakes?

It is proper that this question should be brought up and answered in these columns since it is a question which will doubtless receive wide public attention as soon as the canal is ready for traffic. The commercial interests of the State of New York when they acquire what benefit they are to receive from the enormous expenditure which the State of New York has made in the construction of this waterway will be very likely to jump at the conclusion that a stupid blunder was made by the engineers who planned the canal in not adapting it to vessels which could navigate Lake Erie at least, so that cargoes could go through without breaking bulk from any of the Lake Erie ports to tidewater.

It was not, however, by a blunder that the canal was built in this manner. On the contrary, strange though it may seem, the New York Barge Canal was actually designed with a distinct purpose to prevent its navigation by vessels capable of traversing the Lakes and so that all cargoes would have to be transferred at Buffalo.

To explain how this came about it will be necessary to review briefly the history of the Barge Canal project.

Twenty-five years ago, in the late '80's and early '90's, great interest was aroused in the States bordering on the Great Lakes over the project to extend Lake navigation to the Atlantic seaboard. At that time the grain and flour trade on the Lakes was the largest item of traffic. The iron ore and coal business was of small proportions compared with what it has since become. Railway rates from the Central States to tidewater, on the huge volume of export grain which was then moved to the seaboard were comparatively high. The Erie Canal had lost its former commercial importance and it was clearly recognized would soon become obsolete as a traffic route. Commercial interests were agreed that a water route to take the place of the Erie Canal and designed in accordance with modern traffic requirements was a necessity of the future.

In 1884, the late Elnathan Sweet, a former State Engineer of New York, read a paper before the American Society of Civil Engineers outlining a project for the rebuilding of the Erie Canal as a ship canal capable of carrying vessels of 18-ft. draught. Interest in the Lake cities became more and more active and various conventions were held to further the survey and construction by the United States of a deep waterway from the Lakes to the Atlantic.

In 1895, in response to this agitation in the Lake states, an International Commission was created by joint action of the United States and Canada to study the best route for a deep waterway between the Lakes and the Atlantic. The American members of the Commission were James B. Angell, then President of the University of Michigan, John E. Russell, of Massachusetts, and Lyman E. Cooley, the well known engineer of Chicago.

This Commission was given only a small appropriation and was able to make only a preliminary investigation, but it reported that such a waterway was feasible and recommended a large appropriation sufficient to make complete surveys and estimates. Congress therefore made appropriations for such surveys aggregating nearly half a million dollars and President McKinley appointed as a Commission to conduct these surveys, Major Chas. W. Raymond of the Corps of Engineers, Alfred Noble and George Y. Wisner.

As most of our readers will know these three engineers, all of whom have now passed away, were among the most eminent men in the profession, and their conclusions and recommendations were entitled to great weight. The

Commission spent three years in its work and made complete surveys and estimates for both a 21-ft. deep waterway and a 30-ft. deep waterway from Duluth and from Chicago to tidewater by various routes. It recommended the 21-ft. channel as the most advantageous commercially. The estimated cost of its construction was in round numbers $200,000,000, of which $155,000,000 was the cost of the section from Lake Ontario to tidewater, across the State of New York.

But the commercial interests in the Lake cities which six or seven years earlier had agitated so vigorously for government construction of a deep waterway between the Lakes and the Atlantic paid no attention whatever to this report, when it was presented in 1900. A partial explanation is that the Lake carriers who had a few years earlier been anxious to have an outlet to the Atlantic for their fleet now found themselves taxed to their capacity in caring for the ore and coal traffic to the head of the Lakes. But the more important reason, doubtless, for the shelving of the report and abandonment of the project was that the State of New York had by this time determined to provide its own waterway to the Great Lakes by enlarging the Erie Canal.

While the Board of Engineers for Deep Waterways was at work on its surveys, Theodore Roosevelt, who was then Governor of New York, appointed a commission in 1898 to advise what New York should do with its canal system. The Erie Canal, as has been stated above, was rapidly becoming obsolete and was no longer an important commercial factor. In 1895, the State had made an absurd attempt to do something for the canal by borrowing $9,000,000 to enlarge some of the locks and dredge to greater depth some of the canal levels. The expenditure of this $9,000,000 appropriation was accompanied by scandals which nearly wrecked the administration. It was evident, however, that even if the money had been honestly and efficiently expended, the outlay of any such trifling amount on this shallow old canal was practically wasted.

The Commission which Governor Roosevelt appointed was headed by General Francis V. Greene, a well known engineer. The report of this Commission, presented in 1899, practically ignored the Federal project for a deep waterway from the Lakes to the Atlantic, then under survey and recommended that New York should with its own funds undertake the construction of a waterway to supersede the Erie Canal. The Commission advised that such a waterway should be made large enough to accommodate barges of 1000 tons capacity; and the canal which was afterward undertaken has been generally known as the 1000-ton barge canal. The work has been carried out to a large extent on the lines laid down by that Commission's report, save that the dimensions have been increased so that, in theory at least, barges of a capacity of as much as 3000 tons, will be able to pass through the canal.

The interesting point, however, is the consideration which caused the Commission and the legislature which acted upon its recommendations to fix upon a canal of this type. It should be understood that the only two sections of the State which took any great interest in the canal project were New York City and Buffalo. Other sections of the State, even along the canal line, were either lukewarm or strongly opposed to the assumption of a huge debt by the State for this purpose. New York City, clinging to the old tradition that her greatness was due to her location at the mouth of a waterway from the West, would have been satisfied with any waterway of large capacity, that projected by the Federal Government commission, for example. Buffalo, however, which had really fathered the project for enlarging the Erie Canal, was insistent upon one thing: that the waterway built should not be of such capacity that the lake traffic could pass her docks without stopping. What Buffalo wanted was a waterway across the State which would move traffic at the lowest possible cost and yet would not be large enough to admit vessels capable of navigating the lake!

It seems strange indeed, as we look back upon it now, that this huge engineering work—the greatest piece of waterway construction ever undertaken in the United States and probably the largest piece of public work ever undertaken as a State enterprise—should have been deliberately planned, not with a view to give the greatest public benefit, or even the greatest benefit to the State itself which paid for the work, but with the distinct object of protecting the commercial interests of a single city of that State.

Such, however, is the absolute fact. Buffalo's interest in the Barge Canal was as a means of building up her commerce and increasing the value of her real estate. Any proposal for permitting the Lake commerce to pass her doors without paying tribute, she would not hear of for an instant.

The mistake New York was making in adopting plans for a canal which would accommodate nothing but barges, instead of a channel which could be used by lake and coastwise vessels also without transferring cargoes at the terminals, was pointed out again and again in the columns of ENGINEERING NEWS. Attention was called to the fact that in view of the interest which had been taken by the Lake States in the project for a deep waterway between the Lakes and tidewater, New York could easily secure their coöperation and probably have the entire work undertaken by the Federal government or that it could at least do so if New York would offer to bear half of the expense, which would have made a much smaller burden for her than that which she shouldered in constructing the barge canal. At one time, as our older readers may recall, we published a symposium presenting the opinions of a dozen engineers standing at the head of the profession, all agreeing as to the unwisdom of the project which New York was entering upon.

We deem it proper to review this past history here, because it will undoubtedly be said that the engineers were to blame in not designing the New York Barge Canal for economic transportation. It is well to have on record the fact that it was not lack of engineering foresight or knowledge but the desire to further special interests which determined the type of New York's $100,000,000 waterway.

It is fair to add, however, that some economic facts which bear upon the problem were less widely known fifteen years ago than they are today. If those who represented Buffalo, for example, in furthering the canal enterprise, had understood as they would today the enormous expense involved in transferring freight compared with the cost of hauling it, they might have been less insistent that the canal must be so built as to compel transfers at Buffalo, since they would have realized the danger that a traffic route thus handicapped would very

likely prove unable to attract any large volume of traffic in competition with other routes.

Further than this, as was shown in these columns some weeks ago (Eng. News, July 9, p. 90), the passage of commerce through a city, even where a transfer is involved, is nowadays a very small factor in the city's growth and prosperity. Galveston has after New York the largest foreign trade of any port in the United States, yet Galveston has only 37,000 population, while Buffalo is a city of over 400,000. Buffalo's commerce would benefit far more from a canal able to pass the Lake freighters than from the present canal which requires a transfer of cargo.

Subject to the limitation above noted it was endeavored to design the barge canal as an economic waterway. The canal locks were made phenomenally large for a barge canal because at that time towing of a fleet of barges by a single power boat was in great favor as an economical system of transport, especially on the Lakes. The evolution of the past fifteen years has been away from that system and toward the practice of giving each vessel its own motive power.

Probably the most serious handicap of all to the use of the new canal by vessels which could also navigate the lakes, is the numerous fixed bridges across the canal with a clear headway of only 15½ ft. This is an even more serious restriction to the boat designer than the limiting depth of 12 ft. If movable bridges instead of fixed bridges had been built over the canal, it would be possible to design a roomy freight carrier with shallow draft and very broad beam and to obtain a fair degree of longitudinal strength in its hull notwithstanding its shallow draft, by giving it a very high freeboard. Such a boat would be only fitted for slow speed, it is true; but it would be seaworthy enough to operate with reasonable safety on the lower Lakes during most of the season. The low headway under the fixed bridges, however, seems to shut off any possibility of the use of such vessels and restricts the use of the canal to low barges and tugs.

Of course, it will be freely admitted that to interpose possible interruptions to railway and highway traffic by a line of drawbridges over the canal extending from east to west clear across the State of New York would be a very serious matter. If, however, New York desired a great commercial waterway to extend across its territory, that is part of the price it would have had to pay.

As an alternative, a deep waterway could have been built at no greater cost by the St. Lawrence River and Lake Champlain route; and now that Canada with commendable enterprise is enlarging the Welland Canal to accommodate the largest lake steamers and is likely to enlarge the St. Lawrence canals eventually, either that or the route wholly through Canadian territory to the Gulf of St. Lawrence, is the probable future outlet for the Lake shipping to the Atlantic.

That the New York Barge Canal with its compulsory transfers at each end could not compete as a through traffic route with such a waterway is obvious.

Letters to the Editor

Trade Catalogs Wanted by South American Engineers

Sir—I should be glad if you would insert a paragraph in your widely read journal to the effect that The Institution of Engineers of the River Plate, of which I have the honor to be President, would be glad to receive and file for reference of members catalogs of engineering materials which manufacturers may desire to introduce to this market. The address of the Institution is 25 de Mayo 195, Buenos Aires, S. A.

Bertram C. Hume.

Field Test Values for Concrete

Sir—The article entitled "Field Tests of Concrete for Municipal Work at Kansas City, Mo.," in Engineering News, Sept. 10, 1914, p. 536, has just come to my attention.

I regret that these otherwise interesting tests are practically valueless because rubber pads were used for cushioning the ends of specimens in the testing machine. When the rubber is under pressure it spreads laterally and outwardly ... which split the end of the test specimen before the true compressive strength of the concrete is attained. The illustration accompanying the article in question shows that this happened to the specimens there reported. So far as can be determined from the illustration, all the cylinders are fractured through one of the ends. In properly manipulated tests the fracture either occurs in the middle of the cylinder, leaving the ends intact, or it originates in the middle and spreads to the ends, the fracture of the ends being a secondary result.

Your editorial on the subject is excellent, but in view of what has just been stated you have shown no satisfactory reason for reducing to a lower value Mr. Aiken's figure of 1500 lb. per sq.in. for 1:2:4 concrete at 30 days. The experience of the writer with a large number of field tests in New York City agrees very well with that figure.

On Living Conditions and Commercial Opportunities in the Argentine

Sir—Replying to M. J. Laronde's letter in your issue of Oct. 15, 1914, I will say that while in Buenos Aires I bought several pairs of shoes for less than 14 or 16 paper dollars a pair, and being intimately acquainted with the representative of the United Shoe Machinery Co. who was installing many shoe-making machines in the

Argentine Republic, I can safely assert that at that time first-class native-made shoes could be bought for less than 7 or 8 U. S. dollars. Also I bought suits made to order for 85 and 90 paper dollars, which is equivalent to 36 and 38 U. S. dollars, respectively, and these suits were equal to those costing the same price in New York City.

I do not wish it to be understood to mean that French influence predominates in every enterprise in the country; and if Mr. Lorente will read again my letter of Sept. 5, 1914, he will find the statement that, "South America has in the past secured its capital in Europe . . . and for this reason the English have large interests there."

It is true that in business circles the "British influence has been infinitely more powerful than that of the French," but not so in the matters of tastes, culture, methods of living and the like.

British enterprises are quite naturally managed in accordance with British customs and their structures built according to British standards. This is also true of other nationalities having holdings in the republic, and I do not dispute the fact that British holdings in the country are very large and numerous. Neither do I wish to belittle the vast interests held by the Germans, for the writer has referred to the German "aggressiveness" and its result.

It must be borne in mind that Buenos Aires is a cosmopolitan city and that practically one-half the population is of foreign birth, and about one-fifth are Italians. It is therefore to be expected that to a certain degree the Italian influence is felt. Engineers of various nationalities are to be found in the republic and in the employ of the government.

In the matter of sports, many English games have become popular with the Argentines, among which are football, rowing and wrestling; but it is equally true that sports and amusements of other nations are enjoyed by the people.

It is not the writer's purpose to enter into a lengthy discussion as to the merits of the various views expressed by different ones who have lived in the Argentine, as individual impressions will naturally differ; but the opportunities and conditions existing in a foreign country must be considered from other points of view besides that of engineering to be fairly judged.

E. L. Verveer.

518 West 111th St., New York City,
Oct. 17, 1914.

The Largest Installations of Cooling Towers, it is claimed, are those being made for the Texas Power Co. at Waco, Tex. There is a steel shell 100 ft. long, 18 ft. wide and 40 ft. high, with six pairs of fans 10 ft. in diameter operating at 250 r.p.m., belt driven by motors located above each pair of fans in small motor houses. The fan-housings are extended from the shell and are provided with doors so that they may be opened to permit unobstructed entrance of air for winter operation under natural draft. There is a platform serving the three motor houses and reached by a ladder from the ground. An upper gallery is built on the level of the water distributor and regulating valves which control the discharge to each compartment of the shell. Any section may be cut off for inspection or cleaning without interfering with the operation of the others. Plans are made for an additional installation of equal capacity at one side of the present outfit, which is designed to cool 600,000 gal. per hour. These towers were made by the Wheeler Condenser & Engineering Co., of Cartaret, N. J., at the direction of Sargent & Lundy, Consulting Engineers, Chicago.

The Twenty-First International Irrigation Congress

By F. H. Newell*

The restoration of confidence in irrigation and the continuation of developments in the arid West were the underlying thoughts at the twenty-first International Irrigation Congress at Calgary, Canada, Oct. 5 to 8.

The confidence which is so essential to further irrigation development must come through achieved success in the work already undertaken. In other words, the settler now on the ground, who is producing crops from the irrigation works already built, must be in a prosperous condition before other settlers and other works can be had. If the average irrigator is contented and prosperous, he will attract new men to the opportunities offered. It must, therefore, be seen that the man on the ground is making good, and when this is done there will be little to fear for the future.

These and similar ideas were developed at the Congress. It was shown that the construction of irrigation works and the reclamation of arid land are still in advance of the problem of settlement. There are now millions of acres of good land provided with water at a cost of upward of fifty dollars an acre which are not being tilled. The settlers on these lands are achieving a certain degree of success, but the great need is for more money, or cheaper money, in order to make it practicable for the settler to utilize his opportunities to the largest degree. He needs more livestock, more machinery, better tilling of the soil. Although the security which he can offer is fairly good, his opportunity to borrow money is limited, and the rates charged him are from 8 to 12%, or even more—enough to destroy any less prosperous business.

It was urged that while the reservoirs should be retained by the Government under careful supervision, the irrigation works themselves should be turned over to the people benefitted at the earliest practicable moment, under some form of organization such as the irrigation district, created under state law and having power of taxation. The present voluntary irrigation associations are found to be largely powerless to enforce the will of the majority, but the irrigation district, with powers comparable to those of a municipality, can and will enforce proper rules, and will deal effectively with present evils, such as those of the "water hog" who is wasting water to the detriment of the community. While the Government may be practically powerless in these matters, local public sentiment, enforced by a strong organization, can reach the desired end.

No new projects should be undertaken until the present schemes initiated under the Carey Act or by private enterprise have been thoroughly investigated. If, as a result of such investigation, some of these schemes appear to be meritorious, effort should be centered on completing them, but with the understanding that no work should be approved, either for Government or private investment, unless it appears that it can bear an interest charge of at least 3%. During the first three or four years, however, no interest should be paid, but an equivalent amount should be added to the construction cost and distributed over annual installments to be paid in the future.

*Director, U. S. Reclamation Service, Washington, D. C.

The majority of large irrigation projects initiated under the provisions of the Carey Act or of irrigation districts so far have not been financially successful. The General Land Office has presented figures showing that of the 3,700,000 acres segregated at the request of various states, under the law of 1894, there have been reclaimed and patented about 438,000 acres, as follows:

State	Acres	State	Acres
Idaho	217,000	Montana	15,000
Oregon	45,000	Wyoming	131,000

In addition to the above, there are pending 384,000 acres, so that there is reasonable probability of patents issuing to about 822,000 acres of lands reclaimed under the terms of this Act. Possibly, other projects may be completed so that we may expect that ultimately there will be reclaimed nearly a million acres. There are 31 projects which are at a standstill, involving 1,500,000 acres, and these may be considered to be wholly, or in part, failures. The difficulties are about as follows:

No. of projects	Conditions	Areas involved, acres
9	Financial troubles	350,000
6	Difficulties unknown	180,000
5	No water	125,000
4	Defective engineering	200,000
3	Defective titles	145,000
3	Accidents after construction	65,000
1	Bad management	70,000

Eleven projects, involving 500,000 acres, have succeeded fairly well.

The irrigation districts organized under state law have had a somewhat similar history, but as a result of the experience gained the laws are being improved, so that now we have every reason to hope that districts can be successfully organized and operated under state law. The advantage which this plan possesses is that the irrigation district has behind it, with possibility of taxation, all of the real estate and other values within the confines of the district. Even if disaster comes, there is possibility of renewing effort through wise exercise of the taxing power.

As the outcome of the discussion of the above mentioned and other topics, the congress was convinced that it still has a mission to perform and continued its permanent organization with a view to meeting probably in California in 1915, future activities to be concentrated largely on the problems of settlement and of securing the prosperity of the irrigator.

A Simplified Solution for Some Statically Indeterminate Problems in Building Construction

By G. A. Maney*

Two properties of the bending-moment curve for beams are used in this article to simplify the solution of all problems involving statically indeterminate bending moments. These properties are:

(1) The area under the M/EI curve, between any two points on the elastic curve, measures the change of the slope of the elastic curve between these points. M, E and I represent the bending moment, the modulus of elasticity of the material and the moment of inertia of the beam section, respectively.

(2) The statical moment of the area under the M/EI curve between any two points on the elastic curve, about one of these points, measures the deflection at this point from the tangent to the elastic curve at the other point.

These properties have long been well known among authorities on the subject of mechanics, but their great possibilities for indeterminate problems have been neglected. Their simplicity and ease of application to such problems, as compared with applications of the principle of least work and of the differential equation of the elastic curve (generally used at the present time), makes this method of solution a desirable one.

By the use of the two properties mentioned, we are enabled to write directly, from simple inspection of the M/EI curve, as many simple linear equations between the bending moments as are necessary for a complete solution.

The method here described has been used to advantage by the Illinois Experiment Station. It simplified the analysis of the results of tests of reinforced-concrete construction with reference to combined slab (beam) and column action in resisting bending moments due to loads applied on only one panel, or eccentric loading.

Two specific problems will be worked through by this method to demonstrate its ease and simplicity of application.

A proof of the above-cited properties, which are probably not very widely recognized among engineers, will be given, after which the problem of the elevated slab for the Soo Line Chicago freight terminal will be solved.

An excellent illustration of the application of these properties is found in the extremely short and direct derivation of the theorem of three moments, given at the end of this article.

Proof of Properties

Let

M = bending moment;

I = moment of inertia of the sectional area of the beam;

E = modulus of elasticity of the material;

c = distance from the neutral axis to the extreme fiber;

ds = element of length along the neutral axis;

$d\theta$ = increment of slope in the distance ds due to bending.

1. At any point on the extreme fiber of a beam, Fig. 1, we have the unit-stress Mc/I and the corresponding stretch or compression for length ds is, therefore,

$$\frac{Mc}{EI}\,ds$$

We obtain the change of slope in the distance ds by dividing the deformation for a distance ds along the extreme fiber by c, the distance from the extreme fiber to the neutral axis.

The slope increment in the distance ds is, therefore,

$$d\theta = \frac{M}{EI}\,ds$$

A glance at the M/EI curve, Fig. 2, makes it evident that the quantity $(M/EI)\,ds$ equals the area under that curve for a distance ds along it. The sum of the changes of angle in lengths ds equals the total change of

*Assistant Professor, General Engineering Department, ...

the slope; in other words, the sum of all the elementary areas $(M/EI)\ dS$ between any two points of the beam equals the area of the (M/EI) curve between these two points. Therefore, the area under the M/EI curve between any two points is an exact measure of the change in angle between the two tangents to the elastic curve at these points, due to bending.

II. Suppose we desire the deflection of the point N' from the tangent MN.

We will assume here that the displacements of the neutral axis due to bending are so small that the projection of the neutral axis after bending upon the neutral axis before bending has practically the same length as the neutral axis before bending. This is the assumption commonly made in deriving the differential equation of the elastic curve.

Let S, Fig. 1, be the distance from the middle of ele-

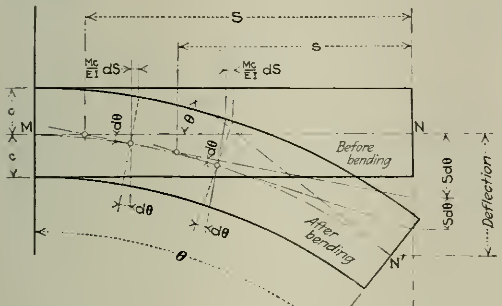

FIG. 1

FIG. 2

FIG. 1. PORTION OF BEAM, ORIGINAL AND BENT POSITIONS

FIG. 2. MOMENT DIAGRAM OR $\frac{M}{EI}$ DIAGRAM

mentary portion dS to the point N whose deflection is desired. The effect of the elastic curvature $d\theta$ of the portion dS upon the deflection at N is measured by the product $S\,d\theta$. But $d\theta$, as previously proved, is equal to the area of the $\frac{M}{EI}$ diagram corresponding to the portion dS; therefore, the product $S\,d\theta$ is the statical moment of this area about the point N'' corresponding to N, whose deflection is desired. It follows that the total deflection at N, being due to the bending in all the elementary portions dS, is equal to the statical moment of the entire M/EI curve about point N''.

APPLICATION TO ONE-STORY BENT, SOO TERMINAL

In load tests of the reinforced-concrete Soo line freight terminal at Chicago, made under the direction of Prof. A. N. Talbot, a question of statically indeterminate bending moments came up. An attempt was made to analyze the action of the structure with one panel loaded and all the adjacent panels empty. The object of the analysis was to determine what effect the relative moments of inertia and lengths of the sections of the floor and the columns would have upon the bending moments.

The conditions which were assumed as being approximately true in one of the analyses made are represented in Fig. 3. For the heavy elevated-track floor slab a condition of approximate fixity was assumed for the outside edges of the panels surrounding the loaded area, and also for the bottom or base of the columns. The column and slab moments were to be determined.

The problem was first solved by the method of least work, and values for the various moments were obtained which checked themselves in all the limiting cases. Then the method here described was used, and an exact check was obtained for every value. The amount of detailed analysis necessitated was only about 10% of that required by the analysis based on the principle of least work.

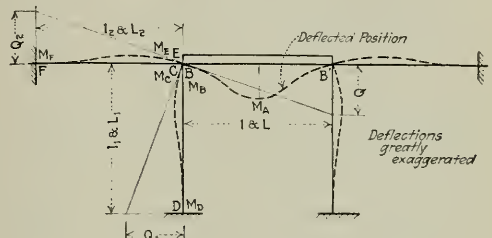

FIG. 3

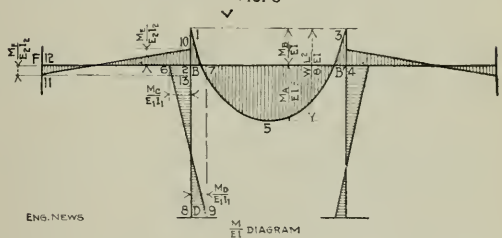

FIG. 4

FIG. 3. ONE-STORY BENT ANALYZED FOR SOO TERMINAL TESTS

FIG. 4. MOMENT DIAGRAM FOR SOO BENT

As sketched in Fig. 3, there are six unknown bending moments, M_A, M_B, M_C, M_D, M_E and M_F. Between these six unknowns, we can only set up two equations from the conditions of statics. These are

$$M_B = M_E + M_C \qquad (1)$$

$$M_A + M_B = \tfrac{1}{8}\,w\,L^2 \qquad (2)$$

The remaining four equations can be written with the aid of the two moment-curve principles above demonstrated. The distribution of the M/EI values is indicated by the curves of the diagram Fig. 4.

The condition of rigidity of the joint at B means that the two tangents at this point are always perpendicular to each other. From this condition we get two independent equations:

$$\frac{Q}{L} = \frac{Q_2}{L_2}, \text{ and } \frac{Q_1}{L_1} = \frac{Q_2}{L_2}$$

Here Q, Q_1 and Q_2 are the deflections of the points B', D and F. The deflection Q is measured by the statical moment of the area 1-5-3-1-2, Fig. 4, about B', or the

moment of the area 1-5-3 minus the moment of the area 1-2-1-3.

Therefore

$$Q = \frac{\frac{1}{3} w L^2 \times \frac{2}{3} L \times \frac{1}{2} L - M_B \times \frac{1}{2} L \times L}{E I}$$

The deflection Q_2 is measured by the statical moment of the area 12-2-10-11 about the point F, equal to the moment of the area 11-13-10 minus the moment of the area 12-11-13-2.

Therefore

$$Q_2 = \frac{(M_F + M_F) \frac{1}{2} L_2 \times \frac{2}{3} L_2 - M_F \times L_2 \times \frac{1}{2} L_2}{E_2 I_2}$$

And knowing that Q/L equals Q_2/L_2 we get

$$\frac{\frac{w L^3}{3 \times 8} - \frac{M_B L}{2}}{E I} = \frac{\frac{(M_F + M_F) L_2}{3} - \frac{M_F L_2}{2}}{E_2 I_2}$$

Also since Q_1/L_1 equals Q_2/L_2 we get

$$\frac{\frac{(M_C + M_D) L_1}{3} - \frac{M_D L_1}{2}}{E_1 I_1} = \frac{\frac{(M_F + M_F) L_2}{3} - \frac{M_F L_2}{2}}{E_2 I_2}$$

The deflection of the point B from the tangent to the elastic curve at D is zero since the point B remains unchanged and the tangent at D is fixed by the conditions of the problem. Therefore, the statical moment of the area 8-2-6-9 about the point B is zero, or, what is the same, the moment of the area 6-9-7 about the point B minus the moment of the area 2-7-9-8 about the point B is equal to zero. From this we get

$$\frac{(M_C + M_D)\left(\frac{L_1}{2}\right)\left(\frac{L_1}{3}\right) - M_D L_1 \left(\frac{L_1}{2}\right)}{E_1 I_1} = 0$$

or

$$M_C = 2 M_D$$

The same thing being true with regard to the tangent at the point F we may immediately write

$$M_E = 2 M_F$$

The relations indicated in these two equations may be also derived [illegible] of the elastic curve for these end conditions.

Assuming that the modulus of elasticity is the same in [illegible] and simplifying we get

$$M_B = M_C + M_E \tag{1}$$

$$M_A - M_B = \frac{w L^2}{8} \tag{2}$$

$$\left(\frac{w L^2}{8} - \ldots M_B\right)\frac{I}{I} = (2 M_C - M_D)\frac{I}{I_1}$$

or

$$\frac{w L^2}{8} - 3 M_B = K_1 (2 M_F - M_F) \tag{3}$$

where

$$K_1 = \frac{L_1 I}{L I_1}$$

$$2 M_C - M_D = K_2 (2 M_E - M_F) \tag{4}$$

where

$$K_2 = \frac{L_1 I_2}{L_2 I_1}$$

$$M_C = 2 M_D \tag{5}$$

$$M_F = \frac{1}{2} M_E \tag{6}$$

Substituting (5) and (6) in (4) we get,

$$M_C = K_2 M_E \tag{a}$$

Substituting (a) in (1) we get,

$$M_B = (1 + K_2)\, M_E \tag{b}$$

Substituting (b) and (6) in (3) we get,

$$\frac{w L^2}{4} - 3\,(1 + K_2)\, M_E = \frac{3\, K_1}{2}\, M_E$$

Therefore

$$M_F = \frac{w L^2}{12}\left(\frac{2}{K_1 + 2 K_2 + 2}\right)$$

$$= \frac{w L^2}{12}\left(\frac{2 I L_1 I_2}{L_1 L_2 I + 2 L L_2 I_1 + 2 L L_1 I_2}\right)$$

$$\therefore M_F = C \frac{w L^2}{12}$$

and

$$C = \frac{2 L L_1 I_2}{L_1 L_2 I + 2 L L_2 I_1 + 2 L L_1 I_2}$$

From (6)

$$M_F = \frac{C}{2}\left(\frac{w L^2}{12}\right) = \frac{w L^2}{12}\left(\frac{L L_1 I_2}{L_1 L_2 I + 2 L L_2 I_1 + 2 L L_1 I_2}\right)$$

From (a)

$$M_C = C K_2\left(\frac{w L^2}{12}\right) = \frac{w L^2}{12}\left(\frac{2 L L_2 I_1}{L_1 L_2 I + 2 L L_2 I_1 + 2 L L_1 I_2}\right)$$

From (5)

$$M_D = \frac{C K_2}{2}\left(\frac{w L^2}{12}\right) = \frac{w L^2}{12}\left(\frac{L L_2 I_1}{L_1 L_2 I + 2 L L_2 I_1 + 2 L L_1 I_2}\right)$$

From (1)

$$M_B = C\,(1 + K_2)\,\frac{w L^2}{12}$$

$$= \frac{w L^2}{12}\left(\frac{2 L L_1 I_2 + 2 L L_2 I_1}{L_1 L_2 I + 2 L L_2 I_1 + 2 L L_1 I_2}\right)$$

From (2)

$$M_A = \frac{w L^2}{8} - M_B$$

It is an easy matter to test some of these values for the limiting cases. Take for instance the value for M_B. There are four conditions of the members BD and BE which would produce a condition of fixed ends for the central span BC. If I_1 or I_2 become very large in comparison with the remaining values of I, or if L_1 or L_2 become very short in comparison with the remaining values of L, we will get a condition approaching fixed ends for the central span. In all four of these cases it is seen that the value of M_B approaches $w L^2/12$, which is the value of the end moment for a fixed span with a uniform load. When these same mentioned values of I and L approach the other extreme we have a condition of a freely supported simple span, where M_B approaches zero, as a substitution will show.

When I_1 equals [illegible], I equals I_2, and L equals L_2, we have the solution of a beam of uniform section with three equal spans fixed at the two end supports and supported freely on the two intermediate supports. Here again the values of M_B and M_E [illegible] themselves by becoming $w L^2/18$, while M_A becomes $w L^2/[illegible]$. For this last case see Fig. 5.

The Theorem of Three Moments

From a theoretical point of view it is interesting to find how simple a derivation of the theorem of three moments becomes when the moment-area method is applied.

Take the case where the two adjacent spans have different lengths and different uniform loads, and the beam section for each span has a different moment of inertia, as indicated in Fig. 6. By the use of the theorem of three moments we obtain $n - 2$ equations between n unknown moments at n supports. The remaining two equations can be written from a knowledge of the degree of fixity of the two end supports.

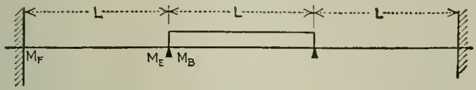

Fig. 5. A Limiting Case for the One-Story-Bent Formulas. ($I_1 = 0$)

For each support except the two end ones we have a condition which determines the relation between the moment at the support considered and the moments at the two adjoining supports. The determining condition is that of continuity at the support considered, which means that the two adjacent spans have a common tangent at this support.

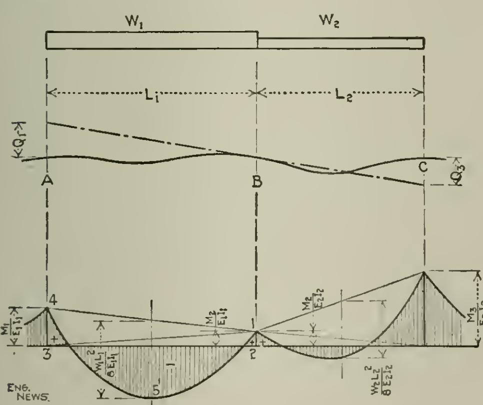

Fig. 6. Portion of Continuous Beam, and Moment Diagram

Let Q_1 and Q_3 be the deflections at A and C, Fig. 6, from the common tangent to the beam at B, the middle support of the three. Let L_1, w_1, I_1 be the lengths, load per lineal foot, and moment of inertia of beam cross-section in the left-hand span, and L_2, w_2, I_2, the corresponding quantities for the right-hand span.

The deflection Q_1 is measured by the statical moment of the M/EI area 3-4-5-1-2 about support A. This again is equal to the moment of the area 4-5-1 minus the moment of the triangle 1-2-3 minus the moment of the triangle 1-3-4, so that

$$Q_1 = \frac{w_1 L_1^2}{8 E_1 I_1}\left(\frac{2 L_1}{3}\right)\left(\frac{L_1}{2}\right) - \frac{M_1}{E_1 I_1}\left(\frac{L_1}{2}\right)\left(\frac{L_1}{3}\right) - \frac{M_2}{E_1 I_1}\left(\frac{L_1}{2}\right)\left(\frac{2 L_1}{3}\right)$$

Similarly,

$$Q_3 = \frac{w_2 L_2^2}{8 E_2 I_2}\left(\frac{2 L_2}{3}\right)\left(\frac{L_2}{2}\right) - \frac{M_3}{E_2 I_2}\left(\frac{L_2}{2}\right)\left(\frac{L_2}{3}\right) - \frac{M_2}{E_2 I_2}\left(\frac{L_2}{2}\right)\left(\frac{2 L_2}{3}\right)$$

Since $Q_1/L_1 = -Q_3/L_2$ on account of the common tangent over the middle support, we can immediately write the theorem of three moments by substituting and reducing. Giving the moments at the support the minus sign we finally get

$$\frac{w_1 L_1^3}{24 E_1 I_1} + \frac{w_2 L_2^3}{24 E_2 I_2} + \frac{M_1 L_1}{6 E_1 I_1} + \frac{M_2}{3}\left(\frac{L_1}{E_1 I_1} + \frac{L_2}{E_2 I_2}\right) + \frac{M_2 L_2}{6 E_2 I_2} = 0$$

Now, assuming that $E_1 = E_2$ and $I_1 = I_2$, we get the familiar form

$$M_1 L_1 + 2 M_2 (L_1 + L_2) + M_3 L_2 = -\left(\frac{w_1 L_1^3}{4} + \frac{w_2 L_2^3}{4}\right)$$

Annual Convention of the American Electric Railway Association

Th 33d annual convention of the American Electric Railway Association and meetings of the allied bodies of engineers, traffic men, accountants, and claim agents were held in Atlantic City, N. J., Oct. 12 to 16. There was the usual huge exhibition of the affiliated manufacturers and supply dealers; in this were prominent novel developments in track-signal systems, automatic "flagmen," illuminated car signs, vitreous-enamel interior fittings, ventilated and pressed-steel motors, headlights, etc. There was perhaps a falling off in the number of cars shown, in the amount of overhead and track work, in wheels and trucks, and in construction, shop and power-plant apparatus—though the amount of equipment, large and small, was not meager.

The very satisfactory plan was followed of having parallel sessions of the special associations in the mornings and meetings of the present body in the afternoon for consideration of the matters of general interest. In addition to the serious work noted below, an extensive entertainment program was arranged to fill the spare hours of all in attendance. The registration was about 2400—a falling off of some 20% generally attributed to the demands for economy throughout the industry.

American Association

Addresses—Under the title, "Mooted Principles in Valuation," F. W. Stevens, Chairman Valuation Committee New York Central Lines, discussed a single matter—the meaning of "value." It appeared to him very plain in economics and in law that the word had but one true use. This covered the worth of anything, expressed in money, to a willing purchaser. He discussed the rate cases of the U. S. Supreme Court to support his opinion (1) that there was only this one worth and that it applied alike in ratemaking, taxation and condemnation; (2) that it was immaterial whether property was paid for by money from stocks and bonds, or by excess earn-

ings, or was donated, (3) that all property had to be protected alike under the constitutional guarantees and therefore appreciation in worth had to be included; (4) that reproduction cost was not value, though often a means of approach.

Mr. H. C. Donecker, Public Service Ry., Newark, N. J., in a paper "Organization and Functions of a Valuation Staff," quoted extensively from the writings of experienced appraisers to show the cost of appraisals, the methods of procedure, the qualifications of the staff and the use of the valuation results. He recited arguments for having the valuation carried on by company forces, for making it convincing, and for the economy of a committee in charge with divided responsibility.

In the discussion, Philander Betts, Chief Engineer New Jersey Board of Utility Commissioners, advanced the opinion that the purpose of the valuation should affect the make-up of the staff. He favored having the inventory made by a joint force of company and commission employees. Henry Floy, Consulting Engineer, New York, commended Mr. Betts' idea, but called attention to the unfitness of the ordinary construction or operating engineer to prepare a valuation for court or commission scrutiny. He criticized an existing lack of that full cooperation of companies and commissions which was needed for best results.

In "Aspects of Workmen's Compensation Laws," H. A. Bullock, Brooklyn, N. Y., briefly reviewed the economic, social and political conditions which made compensation laws a live issue in so many states. The haste in which the laws were being prepared and the disagreement among expert advisors tended to result in provisions burdensome on both employee and employer; the electric railway industry was advised not to stand by and let unfair measures go to unchallenged enactment.

In the paper, "Electric Railway Securities from the Company Standpoint," Calvert Townley, of New York, called on railway men to stop apologizing for early sins which, he claimed, the public had condoned and in spite of which the public had profited from the utilities as much as the promoters. The large sums needed to develop traction lines to meet the demands made on them could not come from earnings and would come from private investors only when adequate returns could be secured—all of which he claimed should be made evident in the exercise of public control.

"A Zone System of Fares," by R. B. Stearns, of Milwaukee, described the system worked out for Milwaukee to apportion fares equitably according to length of ride. Data on zone operation abroad was also presented. It was voted to reprint the report in pamphlet form for distribution.

Reports—The address of the President, C. N. Black, of San Francisco, was a review of the year's work and a demand for larger rate of return on capital. The annual report of the Secretary-Treasurer, E. B. Burritt, New York, showed that the [illegible] member companies now represented [illegible] of the [illegible] miles of electric-railway track and [illegible] million of the 550 million dollars revenue reported. There are 3000 individual members. Some $75,000 income was received and about $71,000 spent.

The Committee on Education, Chairman, H. H. Norris, New York, reported that it had canvassed the member companies, and had found practically none having apprentice systems, and regular courses of lectures. No instruction of a school nature was found, little cooperation with outside schools, and no system of encouraging educational progress in employees. However, a favorable attitude was noted toward a correspondence-school course under the auspices of the Association. Such courses, arranged for mechanical-shop, electrical-shop, line, track, power-house and substation men were outlined.

The Electrolysis Committee, Chairman, Calvert Townley, New York, reported the formation of a joint national committee on electrolysis and advised discontinuing independent study.

The Committees on Insurance and Fire Protection, Chairman, H. J. Davies, Cleveland, gave statistics of the member companies' experience during the year. The fire losses were the highest of any year but one, and the rate the lowest; the average rate of 56c., it was held, could not be decreased unless present hazards were reduced.

The Joint Committee on Joint Use of Poles, Chairman, W. J. Harvie, of Syracuse, presented revised specifications, which had been worked out by the several interests involved, together with a model agreement. On account of protests that various practices were not universally applicable and, if broadly recommended, would constitute evidence of negligence when not followed, the convention received the report merely as guiding information.

The Committees on Ways and Means and Changes in Constitution recommended raising the company dues from the present range of $15 to $600 (depending on gross earnings) to $25-$750 so that the activities of the association need not be curtailed. This plan is expected to increase the annual revenues by some $16,000 and was unanimously accepted.

A Committee on Compensation for Carrying Mail, Chairman, M. C. Brush, Boston, described the consideration given by the Senate Committee revising mail pay and showed high hopes of fair treatment if proper facts could be presented. A Committee on Federal Relations, Chairman, A. W. Brady, Anderson, Ind., reported efforts to have electric roads recognized as a distinct class from steam roads and, on account of local regulation, exempt from provisions of drastic bills requiring steel cars, block signals, etc.

The work of the new Bureau of Fare Research in securing up-to-date information was presented by the Committee on Cost of Passenger Transportation, Chairman, J. D. Mortimer, New York.

The Public Relations Committee, Chairman, T. N. McCarter, Newark, N. J., transmitted the report of a subcommittee which recommended the establishment of a bureau of public relations to disseminate reliable information and to cooperate with similar bureaus. The report also presented a plan of publicity through Chautauqua lectures, technical education, technical, trade, and economic societies, popular magazines, and newspaper advertising. Eventually, some $50,000 per year was to be sought, but for the present, a start would be made by asking certain leaders of the industry to deliver addresses. A code of utility principles was enunciated, such as follows: (1) Adequate service is the first obligation; ample fares are necessary to provide it and yield a fair return; (2) regulated private ownership is preferable to government ownership or operation; (3) local transportation should be a monopoly; (4) short-term

franchises discourage good service and check growth; (5) capitalization should be authorized on terms which will produce needed funds; and securities previously issued in accordance with law should be valid obligations; (7) adequate wages should be recognized but utilities should be protected against strikes and excessive demands; (8) holding companies are economically sound; (9) in appraisal, all methods of valuation should have due consideration; (10) full and frank publicity should furnish public and investor with proper information.

Engineering Association

Reports—After many routine and organization matters, various techincal reports were presented. The Power Distribution Committee submitted specifications for rubber-insulated wire and cable, for round and grooved copper trolley wire, for high-voltage paper-insulated lead-covered cables, for 600-volt overhead construction and for galvanizing iron and steel. In an appendix, the design of reinforced-concrete poles was briefly outlined.

A Board of Accident Prevention described how greater safety was actually being secured by improved equipment and special devices, by education of general public, of school children and employees, by traffic regulation, etc. A paper on "Accident Prevention," by F. C. Henderschott, New York, gave statistics of the improvement secured by a few of the thousand odd concerns which have instituted safety systems.

The Block Signal Committee, Chairman, J. M. Waldron, New York, supplemented its 1913 report with a new digest of state laws, a bibliography, descriptions of light signals for interurban roads, a summary of new installations, standard rules for operation of trolley-contact signals, a summary of contemplated signal installations, a description of a new automatic train stop (Horne-Crane type), and a paper by Gaylord Thompson on "Braking Distances." A standard spectacle and a standard clearance diagram were offered; the former was accepted by the meeting but the latter was returned for further study in connection with other committees. The operating rules presented, but slightly modified, were accepted as standards. The recommendation was adopted that signal lenses of not less than 8⅜ in. and 5⅜ in. diameter, respectively, should be considered good practice for high-speed and moderate-speed operation.

A Committee on Transportation Engineering gave figures for a single-phase line in the Middle West where trains had secured 158% increase in seating capacity and 122% in ton miles with 76% increase in power consumption. A tendency was reported in freight and express service to use a motor car or locomotive with trailers instead of multiple-unit trains. Several favorable car designs were shown.

The Equipment Committee, Chairman, F. R. Phillips, Pittsburgh, recommended further investigation of the standard specifications for heat-treated axles, of possible standard specifications for gears and pinions, troubles with M.C.B. journal brasses, and car wiring in relation to fire-protection. Standard specifications were presented and adopted for solid wrought-steel wheels; specifications of "recommended practice" were accepted for air-brake hose. As an appendix, a paper by L. M. Clark, of Indianapolis, outlined the existing common faults of car-lighting and the proper use of reflectors and lamps for improvement. Data from a large number of tests were given for guidance in fixing size and character of new equipment.

The Buildings and Structures Committee, Chairman, C. F. Bedwell, Newark, N. J., reported approval by the National Fire Protection Association of last year's protection rules for electric-railway properties. General specifications and a form of contract for building construction were presented for consideration as eventual standards. A synopsis of power-house design was submitted for criticism as a part of proposed study of modern practice.

The Committee on Engineering Accounting, Chairman, J. P. Barnes, Brooklyn, N. Y., showed the need of greater attention to applying overhead interdepartmental charges to cost figures of construction that there be no self deception and false economy. A scheme of account analysis was presented so that engineering and executive departments could compare in detail, the original estimates and final costs, etc.

The report of the Power Generation Committee, Chairman, B. F. Wood, New York, was a collection of papers on (1) status of machine stokers (in which it was held that the field was narrowing down to chain grates for high-ash high-volatile fuels and the underfeed type for other coals); (2) use of special reactance coils to protect power apparatus and feeder circuits; (3) advantages and disadvantages in the use of 60-cycle rotary converters.

At some of the sessions of other allied groups, a few papers of more or less engineering interest were presented; one was particularly notable—"The Accounting Treatment of Depreciation," by Robert Sealy, New York. In this it was urged that many of the difficulties in comprehending the subject would be overcome if so called "depreciation" be treated as a replacement insurance. An insurance scheme of computing annual depreciation contributions was offered, but with the remark that life limits due to wear, accident, obsolescence, inadequacy and public demand were all so uncertain that close computations of annual amounts for reserves were useless.

The Committee on Way Matters, Chairman, C. S. Kimball, Washington, D. C., discussed track foundations for paved streets, T-rails and alloy-steel rails. In regard to foundations, it was stated that permanency was the main object. Many soils considered unfit as a foundation, without concrete, could be made serviceable by drainage. Good foundation drainage hindered stray currents and electrolysis. Practice of rolling subgrade and ballast was increasing and was recommended. Current practice seemed to be away from solid concrete construction. Four types of foundation were recommended. The advantages and disadvantages of T-rail construction in streets were recited and conclusions given from data secured that (1) diverse opinions still excited, (2) granite or brick headers are generally used along gage lines and under heads, (3) portland-cement or asphaltic-cement grout is best for filling the space next to rails, (4) tendency of vehicles to follow rails is about the same with all rails. It was recommended that T-rails in permanent pavements should be 7 in. high. The tonnage of alloy-steel rails rolled continued to decrease; the production of bessemer rails also decreased, but use of open-hearth steel correspondingly increased.

The Heavy Electric Traction Committee, Chairman, E. R. Hill, New York, presented a revised diagram of recom-

[illegible] clearances for overhead conductors, allowing 15 ft. [illegible] in. for direct-current rails, and advised continuing the study of third-rail clearances and electric locomotives.

NEW OFFICERS

The following officers were elected for the parent association: President, C. Loomis Allen, President of the Newport News & Hampton Ry., Gas & Electric Co., Syracuse, N. Y.; Vice-presidents, C. L. Henry, President of the Indianapolis & Cincinnati Traction Co., Indianapolis; J. A. Beeler, Vice-president of the Denver Tramway Co., Denver; L. S. Storrs, President of the Connecticut Co., New Haven; T. S. Williams, President of the Brooklyn Rapid Transit Co., New York.

The Engineering Association elected the following: President, L. P. Crecelius, Electrical Engineer of the Cleveland Ry.; Vice-presidents, John Lindall, Superintendent of Rolling Stock and Shops, Boston Elevated Ry.; B. F. Wood, Chief Engineer, United Gas & Engineering Co., New York; F. R. Phillips, Superintendent of Equipment, Pittsburgh Rys.

The new presidents of the other associations are: M. C. Brush, second Vice-president of the Boston Elevated Ry. (Transportation and Traffic); C. S. Mitchell, Auditor of the Pittsburgh Rys. (Accountants); William Tichenor, Claim Agent of the Terre Haute, Indianapolis & Eastern Traction Co. (Claim Agents); E. H. Baker, Second Vice-president of the Galena Signal Oil Co., New York (Manufacturers). The Secretary-Treasurer is appointed and not elected. The present incumbent, E. B. Burritt, continues in office and serves in similar capacity for the allied associations, except that M. R. Boylan, Public Service Ry., Newark, N. J., serves for the accountants and H. G. McConnaughy, Dearborn Chemical Co., New York, for the manufacturers.

Should Members of the Engineering Profession in Pennsylvania Be Subject to State Examination and License?

The Pennsylvania legislature a year ago created a Commission of engineers which was instructed "to investigate the advisability of licensing engineers, within this Commonwealth, who are engaged upon the construction, maintenance and operation of works, public or private, within this Commonwealth, where criminal hazards are offered to the lives, health and property of the citizens of this Commonwealth; and to recommend to the Governor such measures as, in their judgment, should be enacted into law."

Governor Tener appointed as this Commission John Price Jackson, Samuel A. Taylor, [illegible] S. Webster, [illegible] Herbert Stone and J. Murray Africa. The Commission held public hearings at Pittsburgh on Oct. 15 and 16, at Philadelphia on Oct. 19 and will hold a further hearing at Harrisburg on Oct. 30 at the headquarters of the Engineers' Society of Pennsylvania, which has called a special meeting for that date.

In order to stimulate discussion the Commission has [illegible] a draft of a bill which would require engineers engaged in any sort of professional engineering work, whether civil, mechanical, mining, electrical or marine, to be registered as professional engineers by a State Engineering Board, the practice of engineering of any sort without such registration being made a misdemeanor, punishable by fine and imprisonment.

The hearings at Pittsburgh and at Philadelphia were well attended by leading men in the profession. The sentiment expressed was well nigh unanimous against the proposed bill and in most cases the opinions were adverse to any state interference whatever with the practice of engineering.

A number of those attending the sessions represented engineering societies in Pennsylvania or engineering schools in the state. The Philadelphia Association of Members of the American Society of Civil Engineers held a special meeting at which the proposed legislation was discussed at great length; the final vote was nearly unanimous against the proposed bill.

A committee was appointed to represent the Association before the Commission and prepared a report which is so admirable a summary of the principal arguments against engineers license legislation that we print it in full below.

The State Commission, after conclusion of the hearings, will formulate its findings in a preliminary report to the Governor by Nov. 1 and its final report before the end of the year. The Commission is pursuing a judicial attitude in its inquiry and by its questions of those who appeared before it appeared anxious to obtain constructive criticism as well as destructive criticism. In other words, the Commission appeared anxious to ascertain not merely what were the defects and dangers of the particular bill offered for discussion, but what legislation, if any, is desirable in connection with the practice of engineering to safeguard the public welfare.

The Committee's report above referred to is as follows:

ARGUMENTS IN OPPOSITION TO THE PROPOSED ACT FOR LICENSING PROFESSIONAL ENGINEERS IN THE STATE OF PENNSYLVANIA

The Committee appointed to [illegible] arguments against the proposed Act for licensing professional engineers in the State of Pennsylvania [illegible] to present certain general considerations and then to treat the subject under the following headings:

A. Objections to any plan looking to the licensing of engineers in the State of Pennsylvania.

B. Specific objections to the terms of the particular Act proposed by the Engineers' Commission.

C. A [illegible] plan for accomplishing the avowed purposes of this Act in a more direct and effective manner.

GENERAL CONSIDERATIONS

1. [illegible] for licensing engineers in a given [illegible] that there is the same need of licensing engineers as of licensing lawyers and physicians, whereas the conditions in engineering are, in fact, wholly different from those in law and medicine. In the latter professions the public interests cannot be measurably protected against [illegible] and quacks except through licensing on the basis of individual examinations, although experience has shown that even that safeguard is inadequate for the purpose [illegible]. It may, in fact, be confidently affirmed that no plan of licensing can serve to eliminate unscrupulous, though technically competent men, who will not hesitate to resort to unprofessional practices in so far as that may be possible within [illegible].

In engineering, unlike law and medicine, the public may be protected against incompetent or unscrupulous practice, not by the licensing of engineers, but by state approval of plans before execution, by state inspection during construction and by other means to be set forth in more detail hereafter.

2. The fact that the licensing of lawyers and physicians is required in every state of the Union, whereas provisions for the licensing of engineers is made in only two states (Louisiana and Wyoming), indicates that the fundamental differences, from the standpoint of public interests, between the professions of law and medicine on the one hand, and that of

engineering on the other, are widely recognized. The burden of proof in justification of an Act designed to license engineers in the State of Pennsylvania rests, therefore, upon the sponsors of such an Act.

3 In support of a plan for licensing professional engineers it may be claimed that it is necessary for the promotion of safety and the protection of life, health and property. It will be shown, however, that these ends cannot be attained through such an Act, and that other measures would be far more effective toward their accomplishment.

A Objections to any Plan Looking to the Licensing of Engineers in the State of Pennsylvania

I. The licensing of independently established consulting engineers is objectionable on the following grounds:

(a) That the plan would afford no reliable guarantee that those who pass prescribed examinations will not design unsafe work through incompetency, carelessness, or under pressure of economical restrictions.

(b) It is a well known fact that the test of examination becomes increasingly inadequate as the value to be set upon experience, and sound judgment based on such experience, becomes increasingly important. It is easy, for example, to determine by examination a candidate's qualifications for such minor positions as rodman, draftsman, etc., but difficult to ascertain by such a test a candidate's fitness for an engineering position involving large and varied responsibilities.

It is impossible to carry in one's head the many data which a seasoned engineer would readily command in his normal office environment, where he has access to reference books, filing cases, personal notes, etc., which would readily enable him to find the desired data; whereas such accessories would be of comparatively little value to an inexperienced man. On the other hand, it is easily conceivable that the latter would outstrip the seasoned man in an examination, since it is almost impossible, in an examination, to set the proper value upon ability and experience as distinguished from mere book knowledge.

(c) The field of engineering is so highly specialized, and the various specialties overlap to such a degree, that no individual can reasonably be expected to qualify in a full sense in more than a single specialty and, in a modified sense, in closely related specialties. The term "professional engineer" is therefore meaningless, except in an inclusive way as covering many specialized titles. Such a speciality as railroad engineering, for example, is properly sub-classified under "Design, Construction, Maintenance and Operation." A given individual may deservedly have attained to the highest rank in Construction, although he may command little or no knowledge of Designing. A fair examination in such a case should be limited to Construction; or better still, the personal record of the individual concerned should be accepted as a far better criterion of his qualifications than any form of examination.

(d) That the licensing of engineers will not serve to avert disaster through improper design or construction is attested by the calamitous failures that have at times attended engineering operations under the direction of engineers deservedly recognized as among the ablest members of the profession—men who would unquestionably have qualified under a proper examination.

II. The licensing of salaried engineers, as distinguished from independent consulting engineers, is objectionable on the following grounds:

(a) The great majority of engineers (probably not less than 90%) hold salaried positions, and the legal and moral responsibility for their professional work should fall on the employing municipalities, corporations or firms, by whom their competency can also be far better determined than through the operation of any legislative Act. The licensing of such engineers would therefore serve no useful purpose, and would be an unnecessary source of expense and annoyance to those affected.

(b) No scheme of examination that can be devised is as effective for determining the degree of professional competency as the principles ordinarily governing the employment, promotion and discharge of salaried men.

(c) Every salaried engineer upon merited promotion to a position of a certain higher responsibility would have to pass an examination prescribed by the state. His rejection upon such an examination would work an undeserved professional injury to the individual concerned, and would justly tend to bring ridicule upon the examining system.

(d) In the promotion of engineers to positions of higher responsibility by corporations whose activities extend beyond the state, such as railroad companies, public-service corporations, etc., the transfer of an individual from another state to Pennsylvania could not take place without subjecting him to an examination involving the contingencies just mentioned.

B Specific Objections to the Terms of the Particular Act Proposed by the Engineers' Commission

I The indefiniteness of certain important features in the proposed Act.

In Section 1, Paragraph 1, the Act is made applicable to those charged with "the designing or general supervision of the operation and maintenance to a greater or less extent of public or private works, etc." The term "greater or less extent" is so indefinite that it may well be asked whether such officers, for example, as railroad supervisors would come under the provisions of the Act.

On the other hand, according to Section 20, Paragraph 2, one of the classes under "Limitation and Scope of Act" is described as "any professional engineer employed as an assistant to a registered professional engineer." This may fairly be assumed to mean that the chief engineer of a railroad company or the chief of a municipal bureau would be required to register as a "Professional Engineer," whereas the innumerable engineers of subordinate rank would be exempt. It is evident that an engineer of subordinate rank on an engineering operation of first magnitude may be charged with much heavier responsibilities than the chief engineer of an engineering operation of minor importance. Again, engineers in subordinate positions on important engineering works may command specialized knowledge not possessed by the chief engineer.

II Certain features of the proposed Act are apparently contradictory.

Thus, in Section 3, Paragraph 3, it is stated among the requirements for eligibility to examinations that the candidate must have "had charge of engineering work as principal or assistant for at least one year." whereas by Section 1, Paragraph 1, only "Professional Engineers" can be "in charge" of engineering work. If these terms were enforced it would apparently mean that an engineer in order to qualify for an examination as "Professional Engineer" in Pennsylvania must have had charge of engineering work in another state for at least one year.

III The proposed Act is incomplete in failing to provide for certain important features, as, for example, the following:

(a) The professional complexion of the examining board. Modern engineering is so highly specialized that it may be confidently affirmed that an examining board consisting of only nine members, no matter how otherwise constituted, would be incompetent to supervise examinations in every important engineering speciality.

(b) Since no individual can possibly qualify as a "Professional Engineer" in the inclusive sense, the act should indicate by title, and define as to scope, the various divisions of professional engineering in which candidates may qualify by examination. The difficulty of doing this is manifest, and this only serves to indicate the futility of determining the competency of engineers for high professional services through examination.

(c) The progress in engineering, especially in certain lines, is so rapid that an engineer who may readily pass a fair examination at a given period, may be utterly unable to qualify under an uptodate examination five or ten years later, unless he has kept well abreast of progress. Therefore, if examinations are to be applied as a test of competency, they should be reapplied at suitable intervals, as is the practice, for example, in the U. S. Army and Navy.

(d) It should be explicitly stated in the Act that the engagement of a professional engineer will not serve to absolve the employer of such an engineer from legal responsibility for his acts and their consequences; that is to say, that it will not shift such legal responsibility either upon the professional engineer or upon the State.

IV The terms of the Act fail to make adequate provision for its application, in that an examining board of nine members, assisted by one secretary and one stenographer, cannot possibly meet the practical requirements entailed.

V The proposed terms of the Act are objectionable in that:

(a) The members of the examining board (Section 3, Paragraph 6) "shall serve without compensation" and shall only be allowed "expenses actually and necessarily incurred in the performance of their duties." If under the head "necessary expenses" the act is intended to provide for the engagement of a corps of examining specialists, membership on the examining board without compensation would be apt to be viewed as an honorary appointment involving comparatively slight demands on time and energy. If, on the other hand, the examining board should be expected personally to prepare the examination questions and to examine the examination papers, it is wholly unreasonable to expect engineers of high professional standing to render such service to the state without liberal remuneration. Moreover, it is both undignified and unfair for a great state to expect individuals

to render professional services of such a high grade and such great value at their personal sacrifice. In this respect, [illegible] tions in engineering under an adequate interpretation of the purposes of this Act differ radically from those in law and medicine. The examinations for licenses to practice the latter professions are designed to test inexperienced graduates of law and medical colleges as to their knowledge of such fundamental principles as they may fairly be expected to [illegible]. The conduct of such examinations is a comparatively simple matter. In engineering, on the other hand, examinations designed to accomplish the expressed purposes of this Act would have to be of a specialized kind and of advanced grade to test the fitness of the candidates for high professional responsibilities.

(b) No exemption is given to those members of the profession who hold responsible teaching positions, as is the practice of leading national engineering societies. This paragraph should be amended by adding the following sentence, quoted from the Constitution of the American Society of Civil Engineers:

The performance of the duties of a professor of engineering in a technical school of a high grade shall be taken as an equivalent to an equal number of years of actual practice.

VI. Other features of the proposed Act are fairly open to question and criticism, but it is thought best to limit this report to what may be regarded as its most vital features.

C. A Proposed Plan for Accomplishing the Avowed Purpose of the Act in a More Direct and Effective Manner

Assuming that the proposed Act is designed solely as a protection to public interests, as stated in its title, and is not designed to elevate professional standards or to promote the pecuniary interests of the members of the engineering profession, its purpose may be accomplished much more directly and effectively through legislation to the following ends:

(a) To create a State Engineering Department, Board or Commission by which engineering designs which may involve public safety would have to be approved before execution. This Department, Board or Commission should also be charged with the inspection of engineering works during construction at such intervals and to such extent as may be deemed proper.

(b) To exempt from the supervision of this Department, Board or Commission, work designed and constructed by municipalities and approved corporations, such as railroad companies, etc., which are not only legally responsible for, but have an immediate and lasting interest in engineering operations conducted on their behalf and under their supervision.

(c) To require the licensing of county surveyors and other surveyors in independent practice. Fair examinations for surveyors can easily be set, which would serve to exclude incompetent men whose incompetency would be likely to entail property losses and expensive litigation.

(d) To license other classes of technical men whose duties are of a definite and restricted nature in fields where incompetence would be attended by results similar to those just mentioned in connection with surveyors, and in which competency may readily be determined by examinations.

[illegible]

First: That laws under which engineering designs must be [illegible] examined before their execution are in satisfactory operation in certain European countries.

Second: That such laws tend to deter incompetent engineers from preparing designs without competent assistance.

Third: That the Act under review is inadequate as a measure of protection to public interests.

Fourth: That this Act is objectionable in that it will [illegible] as "Professional Engineers" men who, [illegible] the professional [illegible], can safely be entrusted with the responsible direction of engineering works. The [illegible] will tend to [illegible] confidence [illegible] of the public to a degree [illegible].

Fifth: That in so far as this Act may tend to deter the [illegible] its effect would be [illegible] to public interests.

Respectfully submitted,

[illegible], Chief Engineer, [illegible]; John W. [illegible], [illegible] Engineer, American [illegible] Co.; H. [illegible] Engineer of Bridges & Buildings, Pennsylvania R.R. Co.; [illegible], Chief Engineer, Dept. of City Transit; [illegible], Chief Engineer, [illegible] State Construction [illegible]; [illegible], Asst. Chief Engineer, Pennsylvania R.R. Co.; Samuel [illegible], Asst. Engineer, Philadelphia & Reading Ry. Co.; [illegible] (Chairman), Professor of Civil Engineering, University of Pennsylvania.

Committee of the Philadelphia Association of Members of the American Society of Civil Engineers appointed to represent that Association in opposition to legislation for licensing professional engineers in the State of Pennsylvania.

NEWS NOTES

A Cave-In in a Sewer Trench in South Bend, Ind., on Oct. 13, caused the death of three men.

Earthquakes Are Reported in Greece, where considerable damage has been done at Thebes, Chalcis and Athens.

A 20-In. Water Main Burst, on Oct. 16, at the corner of Second and Market St., Philadelphia, Penn. Water flooded the basements of several business establishments, and for a time threatened to tie up traffic in the subway.

A Collision Occurred in the New York City Subway on Oct. 17, at the 116th St. station of the Lenox Ave. line. Failure of the brakes of a northbound train caused it to collide with the rear of the train ahead just as the latter was leaving the station. No one was seriously injured, but the insulation of one of the motors was so damaged as to set fire to the car.

Two Sewer Cave-Ins occurred in Toronto, Ont., Oct. [illegible]. A wagon loaded with coal and drawn by a team of horses went through an apparently sound pavement on Marguerretta St., falling into a cavity 10 ft. deep over a sewer cave-in. The driver was uninjured but one of the horses was killed. A cave-in during the construction of a new sewer on [illegible] Ave. buried three men on the same day. No one was seriously injured.

A Slide in Culebra Cut, Panama Canal, on Oct. 1[illegible], entirely closed the channel about 1500 ft. north of Gold Hill for a distance of several hundred feet. The slide was on the east bank of the canal. It is also reported the bottom of the channel is being forced up on the west side. Dredges were at once set to work, and on Oct. 20 the canal was again opened for traffic, a new channel 1[illegible]0 ft. wide and [illegible] ft. deep being dredged at record speed.

The 5000-ton Steamship "Metapan" Was Sunk by a collision with the 8000-ton steamship "Iowan," at the entrance to Ambrose Channel, New York Harbor, Oct. 1[illegible]. The "Metapan" of the United Fruit Co. was inbound from Colon and the West Indies, and the "Iowan" of the Hawaiian-American Line was outbound. The passengers and crew of the wrecked steamship were saved. The "Metapan" was headed for shore and was beached in 1[illegible] ft. of water a few minutes after the collision.

A Boulder Fell on a Passenger Train on the Denver & Rio Grande R.R., [illegible] miles east of Grand Junction, Colo., on Oct. 1[illegible]. The accident occurred at a point where the railway tracks closely parallel the Rio Grande with cliffs rising high above the river bank. The train was running at high speed when a rock falling from the cliffs struck the coupling between the tender and the smoking car, which parted the train. Before the cars came to a stop a large boulder fell on the smoking car and day coach following, smashing in the roofs and [illegible] the steel [illegible]. [illegible] passengers in the two cars escaped injury, while three were killed and 11 were injured. Much of the wreckage was swept into the river.

A Pier Fire on the Delaware River waterfront at Philadelphia, on Oct. 1[illegible], destroyed a new pier shed just being completed for the Philadelphia & Reading R.R., causing a loss of about $1[illegible]. The floor of the pier and its foundation were of substantial concrete construction and were uninjured by the fire. The pier shed was a steel structure with [illegible] floors and roof. A small quantity of freight had been placed on the pier, but except for the burning of a few barrels of whiskey the heat of the fire was furnished chiefly by the wooden flooring and roof. The steel structure promptly collapsed on exposure to the flames. The front of the pier facing on the street was of reinforced concrete pierced by large openings. This was not quite completed when the fire occurred, but remained standing, and except for some cracking and spalling was little injured by the flames. Part of the windows in this front wall were of wire glass in steel frames, and this remained intact, no [illegible] through it being made.

The heat of the fire through which this reinforced concrete passed with so little injury was so great as to start fires in storage warehouses protected by fireproof shutters on the opposite side of a 1[illegible] ft. street. The heavy granite piers in the front of the building exposed to a much lower degree of heat than the concrete were badly spalled.

An Industrial Welfare Conference is to be held at Harrisburg, Penn., in the State Capitol, Nov. 17-19, under the auspices of the Engineers Society of Pennsylvania and the State Labor Department. A call for the conference has been issued by Dr. John Price Jackson, Dean of Pennsylvania State College and Commissioner of Labor. The conference held a year ago was attended by over 2000 persons. A safety and efficiency exhibition will be held in connection with the conference.

The Rapid Transit Traffic of New York City in the year ending June 30, 1911, has been reported by the Public Service Commission for the first district. The existing subway lines carried 340,413,103 passengers or 1,001,215 per working day. All of the elevated lines together carried 311,473,568. The Second and Ninth Ave. lines made moderate gains; the Third Ave. line gained heavily and reached its limit of carrying capacity. The Sixth Ave. line, including the west-side line above 53d St., showed a slight decrease.

The First Generating Station owned by the Ontario Hydro-Electric Commission was placed in service Oct. 6. This is at Wasdell's Falls on the Severn River, and has 1200 hp. capacity. It is one of several Severn projects, other sites having been purchased from private owners at Big Chute, Swift Current, Port Severn and Eugenia Falls. When they are connected, the system will have an output of 25,000 hp Heretofore, the Commission has purchased power (notably at Niagara Falls, and transmitted it for distribution and resale by municipalities.

Economies in the Boston, Mass., Health Department—Rather than pay \$5000 per annum rent for a more convenient milk laboratory, the city of Boston has increased the salaries of three milk sample collectors \$100 per annum, and forced them to walk upstairs to the 11th floor of the new City Hall Annex every night. It is the duty of these collectors to go about the city every night and get samples of milk from delivery wagons. The elevator service to the laboratory ceases at 11 p.m., and legal complications prevent the leaving of the milk samples temporarily in some other place. It was proposed to hire the quarters formerly used on Huntington Ave. for \$5000 per annum, so the city fathers figure they have made a saving of \$4700 per annum.

Petty Thieving by Drivers of Garbage Wagons is said to be costing the Boston Development & Sanitary Co., which has a 10-year contract to dispose of the wastes of the city of Boston, hundreds of dollars. When depositing the contents of barrels in their wagons, the men take time to pick out such articles as bottles, old metal and shoes and place them in a corner of the wagon. On the way to the receiving station they transfer these articles to bags and dispose of them to junk dealers. The drivers are, in many cases, adding several dollars a week to their incomes in this way, and the company, rightfully claiming that it is entitled to everything in the wastes, is objecting. The Commissioner of Public Works, L. K. Rourke, has suspended a number of drivers for from one to three days as punishment.

The Street Railway Situation at Detroit—In April, 1913, the city voted for municipal ownership of traction lines and the Mayor appointed a board of street-railway commissioners consisting of wealthy automobile manufacturers. They were charged to report on the best methods for building up a new street-railway system or the purchase and development of the old one. This commission appointed E. W. Bemis to make an appraisal of the existing system and he placed a large force at the task. The local company is reported willing to sell. The Bemis report was due Oct. 15 and probably will be made sometime during the month. Pending receipt of this, the commission called in Wm. Barclay Parsons for advice and subsequently retained the firm of Barclay Parsons & Klapp to report on a comprehensive rapid-transit system. The firm's local investigations are going forward under the direction of H. M. Brinkerhoff and this report is expected in February, 1914.

The Production of Explosives in the United States during 1913 has just been published by the U. S. Bureau of Mines. The total was 463,511,881 lb., compared with 489,393,131 lb. for 1912. This production is seggregated as follows: Black powder, 194,116,717 lb.; "high" explosives other than permissible explosives, 241,682,364 lb.; permissible explosives, 27,685,-770 lb. These figures represent a decrease of 36,146,622 lb. of black powder and an increase of 7,212,872 lb. of high explosives and 3,055,500 lb. of permissible explosives. In 1902 only 11,300 lb. of permissible explosive was used in coal mining, whereas in 1913 the quantity so used was 21,804,285 lb. The quantity of permissible explosives used in the United States is larger than in a number of foreign countries. In 1912 it represented about 5% of the total quantity of explosives produced, and in 1913 6%. The total amount of explosives used for the production of coal in 1913 was 209,352,938 lb., of which about 10% was of the permissible class as compared with 8% in 1912.

Work on the Austin-San Antonio Post Road, in Texas, was begun Oct. 20. The road is being improved under the supervision of the U. S. Office of Public Roads in accordance with the Act of Congress of Aug. 24, 1912. The total length is nearly 83 miles. Parts of the road have previously been surfaced with gravel. It is proposed to rebuild the road 24 ft. wide between shoulders with a surfaced roadway 15 ft. wide. On portions which have not been graveled before the surfacing is to be 12 in. deep. On the best portions of the old graveled sections the surfacing is to be scarified, reshaped and topped with a new 5-in. (loose measure) wearing course. Other sections will have new wearing courses of from 5 to 12 in. thick. The foundation course may be either adobe rock, or gravel, or any rough gravel which will properly compact. The wearing course will be of selected hard gravel, screened to exclude stones over 2 in. in diameter. All large openings in the roadbed will be bridged with reinforced-concrete structures of not less than 20 ft. clear roadway. Smaller culverts will be of vitrified clay pipe or ingot-iron pipe with concrete headwalls. All wooden structures will be replaced. The estimated cost is nearly \$250,000. Local newspapers are rejoicing because the road "will afford employment to hundreds of farmers who will welcome this opportunity to increase their incomes, following a disastrous cotton season."

A Partial Sanitary Reconnaissance Survey of Ohio is being made by the Ohio State Board of Health under the direction of W. H. Dittoe, Chief Engineer. As many of our readers will remember, the board named made an extended investigation of the water-supplies of the state some fifteen years ago, a special investigation of water- and sewage-treatment plants about six years ago and a special study of garbage and refuse disposal some four years ago. The board has also regularly made examinations of the water-supplies and sewerage systems of the state. Mr. Dittoe informs us that these earlier investigations have not taken into account the conditions existing in communities which have not yet provided themselves with the sort of improvements mentioned. Representatives of the board have therefore begun to visit every incorporated community and every public and private institution in the state with a view of determining the existing conditions as regard water-supply, sewerage, and sewage and waste disposal. The work is being done rapidly in order to cover the state in a reasonable length of time, and it is not expected that a complete report based on the information immediately obtained will be published. What is expected is that the board will be able to tabulate for its own information, as well as for the information of those interested, the essential facts relating to all the public and private water-supplies of the incorporated communities and institutions of the state, as well as like information for sewerage and sewage disposal and refuse collection and disposal. It is believed that with this information in a compact form the board will be able to direct an attack upon those conditions in Ohio which are most prejudicial to the health of the state.

The Longest Recorded Drought in Massachusetts was ended when rain began to fall on Oct. 16. The dry period, which began with Aug. 30, lasted for 47 days, during which time the total precipitation amounted to only 0.21 in. at Boston.

The average rainfall at stations on the watershed of the Wachusett River during September, 1914, was 0.15 in. The lowest previous record for any month was 0.48 in. for June, 1912. On the Sudbury River watershed the average rainfall for September, 1914, was 0.29 in., and the lowest previous record was 0.32 in. for September, 1877. At Lake Cochituate the rainfall was 0.27 in. for September, 1914, the lowest previous record having been 0.38 in. for June, 1873. The records have been kept on the Wachusett watershed for 17 years and on the Sudbury watershed and at Lake Cochituate for 50 years.

As no rain fell during the last two days of August and the first 15 days of October, the precipitation record for the month of September is the rainfall for the entire period. It is said that private records show no such long continued drought since 1817.

Unless there are heavy rains during the remainder of the year, 1914 will take its place in the list of exceedingly dry years which began with 1908. The Committee of the New England Water Works Association, which reported on the "Yield of Drainage Areas" at the recent convention in Boston, presented figures on the Wachusett Watershed and called attention to the remarkable fact that the highest yield of any year since 1907 was less than the lowest yield of any one of the preceding 11 years. The importance of this to engineers attempting to estimate the available yield of a watershed is obvious.

PERSONALS

Mr. [illegible] Blackstone, M. Am. Inst. M. E., Chief Engineer of the Homestake Mining Co., Lead, S. D., has been promoted to be Superintendent, succeeding the late T. J. Grier. Mr. Blackstone is a native of Pennsylvania, where he was born 71 years ago.

Mr. W. Cameron Forbes, of Dedham, Mass., former Governor General of the Philippine Islands, has been appointed Receiver of the Brazil Railway Co. and its subsidiary the Madeira-Mamoré Railway Co., both incorporated under the laws of the State of Maine. Mr. Forbes is a graduate of Harvard University, class of 189[illegible], and from 1897 to 190[illegible] was chief of the financial department of Stone & Webster, Electrical Engineers, Boston, Mass.

Mr. [illegible] L. Havens, M. Am. Soc. C. E., has been appointed Special Commercial Attaché of the United States Department of Commerce at Santiago, Chile. Mr. Havens was formerly Chief Engineer of the Mexico City Tramways and more recently has been engaged as Consulting Engineer for various Latin-American enterprises. He is the first civil engineer to be appointed Commercial Attaché. The appointment of three other attachés was also made during the past week.

The following city officials have been appointed under the new charter of St. Louis, Mo., which was outlined in our issue of July 9, 1914, p. 104: Messrs. Edward E. Wall, M. Am. Soc. C. E., Water Commissioner of the Department of Public Utilities; A. L. Jacobs, Supervisor of City Lighting of the Department of Public Utilities; Charles M. Talbert, Director of the Department of Streets and Sewers; J. M. Slater, M. Am. Soc. C. E., former Principal Assistant Engineer of the Wabash R.R., Street Commissioner.

Mr. C. Loomis Allen, M. Am. Soc. C. E., President of the Newport News & Old Point Ry. & Electric Co., Vice-President of the Maryland Electric Rys., and President of the Syracuse & Suburban R.R., of Syracuse, N. Y., has been elected President of the American Electric Railway Association. Mr. Allen was born in Syracuse 41 years ago. He attended Alfred and Syracuse Universities and began his engineering experience as an axman with the engineering corps of the Norfolk & Western Ry. As a member of the firm of Mather & Allen, he had charge of much of the civil engineering work in the electrification of the railways in Syracuse from 1892 to 1895; later he was Chief Engineer and General Manager of the Syracuse street railways.

OBITUARY

William W. Lobdell, President of the Lobdell Car Wheel Co., of Wilmington, Del., died Oct. 10. He was 70 years old.

George A. [illegible], a prominent contractor of Chicago, Ill., died at his home in that city, Oct. 10. He was born in [illegible] in 1811.

[illegible] H. [illegible], Superintendent of Buildings of the [illegible] Service Corporation, Newark, N. J., died Oct. 13, at his home in Flushing, N. Y.

[illegible], a civil engineer for many years with the [illegible] Works, of Brooklyn, N. Y., died at his home in [illegible], Oct. 9.

[illegible], M. Am. Soc. C. E., Civil Engineer and Contractor of San [illegible], Calif., committed suicide at his office at [illegible] St., Oct. 7, by shooting himself [illegible]. He was [illegible] years old and had for some time suffered from heart trouble. He was a [illegible] [illegible]. He is survived by a widow and one son.

[illegible], M. Am. Inst. M. E., [illegible] of the [illegible] Mining Co., San [illegible], Calif., died at his home there Oct. [illegible]. He was born in Trenton, N. J., [illegible] years ago. He was educated in the public schools of Trenton and Philadelphia, and in 18[illegible] graduated in mining engineering from the Polytechnic College of Pennsylvania. For several years he was in [illegible] work in [illegible]. Returning to the East he was for a number of years a prominent consulting mining engineer of Philadelphia and New York City. Since 18[illegible] he had lived in California.

[illegible] S. Lyford, former Vice-President of the Chicago & Eastern Illinois R.R., whose railway experience dated back to 1846, died Oct. 12, at the home of his son in Chicago, Ill. He was born in Maine, June 19, 1823. At 23 years of age he entered the service of the old Boston & Lowell R.R. as a watchman and assistant baggage master. In 1851 he was a passenger conductor. He then left the Boston & Lowell R.R. for the Erie Ry., being for a few months shop clerk at Dunkirk, N. Y., and then a passenger conductor. In 1863 Mr. Lyford became Division Superintendent of the Atlantic & Great Western Ry., and later held the same position with the Erie Ry. Subsequently he was General Superintendent of the Hannibal & St. Joseph R.R., of the Kansas Pacific Ry., and in 1878 first became connected with the Chicago & Eastern Illinois as Superintendent. He was Vice-President from 18[illegible] until about a year ago, when he retired at the age of 90 years, after a total railway service of 67 years.

ENGINEERING SOCIETIES

COMING MEETINGS

NORTHWESTERN ROAD CONGRESS.
Oct. 28-31. Congress at Milwaukee, Wis. Headquarters, 71, Sentinel Bldg., Milwaukee, Wis.

AMERICAN ROAD CONGRESS.
Nov. 9-11. Atlanta, Ga. Permanent headquarters American Highway Association, Colorado Building, Washington, D. C.

INDUSTRIAL WELFARE AND EFFICIENCY CONFERENCE.
Nov. 16-20. Conference at Harrisburg, Penn. Secy., R. M. Pennock, Harrisburg, Penn.

NATIONAL MUNICIPAL LEAGUE.
Nov. 17-21. Annual meeting at Baltimore, Md. Secy., Clinton Rogers Woodruff, North American Building, Philadelphia, Penn.

OHIO SOCIETY OF MECHANICAL, ELECTRICAL AND STEAM ENGINEERS.
Nov. 19-20. Annual meeting at Columbus, Ohio. Secy., F. E. Sanborn, Ohio State University, Columbus, Ohio.

AMERICAN SOCIETY OF REFRIGERATING ENGINEERS.
Nov. 30-Dec. 1. Annual meeting at New York. Secy., W. H. Ross, 154 Nassau St., New York City.

AMERICAN PUBLIC HEALTH ASSOCIATION.
Nov. 30-Dec. 5. Annual meeting at Jacksonville, Fla. Secy., Prof. Selskar M. Gunn, Massachusetts Institute of Technology, Boston, Mass.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.
Dec. 1-4. Annual meeting at New York City. Secy., Calvin W. Rice, 29 W. 39th St., New York City.

AMERICAN INSTITUTE OF ARCHITECTS.
Dec. 2-4. Convention at Washington, D. C. Secy., D. Knickerbacker Boyd, The Octagon, Washington, D. C.

AMERICAN MINING CONGRESS.
Dec. 7-11. Annual meeting at Phoenix, Ariz. Secy., J. F. Callbreath, Denver, Colo.

NATIONAL SOCIETY FOR THE PROMOTION OF INDUSTRIAL EDUCATION.
Dec. 9-12. Convention at Richmond, Va. Secy., C. A. Prosser, 140 W. 42d St., New York City.

SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS.
Dec. 10-11. Annual meeting at New York City. Secy., D. H. Cox, 29 W. 39th St., New York City.

AMERICAN ROAD BUILDERS' ASSOCIATION.
Dec. 14-18. Convention at Chicago, Ill. Secy., E. L. Powers, 150 Nassau St., New York City.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.
Dec. [illegible]. Annual meeting at Madison, Wis. Secy., F. M. White, Madison, Wis.

Society for the Promotion of Engineering Education—The council of the society has decided to hold the 1915 meeting at Iowa State College, Ames, Iowa, June [illegible]. Dean Marston, of Iowa State College, is President of the society.

Albany Society of Civil Engineers—The regular annual meeting and election of officers will be held in Albany, Oct. [illegible]. Richard W. [illegible] will address the society on "Engineering from the Contractor's View Point." The secretary is [illegible] at [illegible], Albany, N. Y.

American Society of Civil Engineers—The nominations of officers for 1915 are [illegible] as follows: For President, Charles D. Marx, Professor of civil engineering at Leland Stanford, Jr., University; for Vice-Presidents, [illegible], Consulting Engineer, New York City; [illegible], Consulting Engineer, Kansas City, Mo.; [illegible], Consulting Engineer, New York City; for Directors, [illegible], Consulting Engineer, New York City; John V. [illegible], Consulting Engineer, New York City; J. E. Greiner, Consulting Engineer, Baltimore, Md.; [illegible], Consulting Engineer, Fort Worth, Tex.; John F. Coleman, Consulting Engineer, New Orleans, La.; Herbert S. Crocker, Consulting Engineer, Denver, Colo.

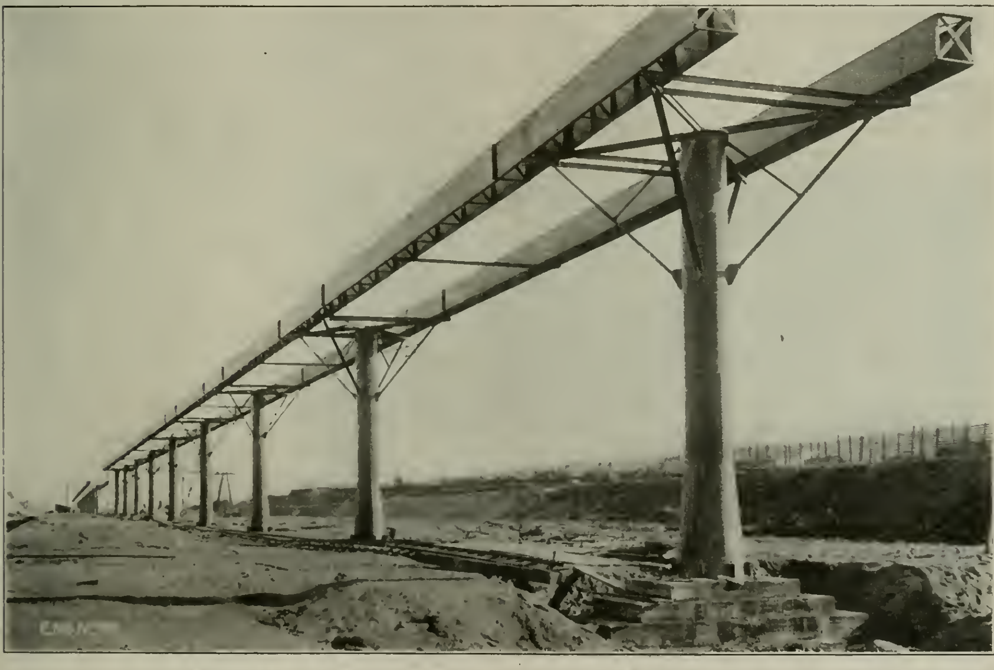
Engineering News

VOLUME 72 OCTOBER 29, 1914 NUMBER 18

A Noteworthy Steel Trestle: Stock-Pile Trestle at Negaunee Mine

Trestles for dumping ore into stock piles at the iron mines are usually wooden trestles of the simplest construction; these trestles are taken down when material is shipped from the pile, to give room for working the steam shovel, which loads the ore into railway cars, and re-erected when the ore is again to be stocked. The Negaunee mine, Negaunee, Mich., five years ago started a new shaft (No. 3), which promised sufficient permanence to justify a better type of stock trestle, one which would save the cost of frequently demolishing and re-erecting and of complete renewal every five or six years, as necessitated by timber trestles. On the suggestions of Stuart R. Elliott*, superintendent of the mine, a center-column steel trestle (allowing steam shovels to work along the ground without interference) was designed by the Wisconsin Bridge & Iron Co., and this trestle has been in service now for two years with satisfactory results. It presents several radical novelties in steel construction.

The trestle is a double-track plate-girder structure of 20-ft. track spacing with a single central line of columns. It is 42 ft. high from ground to rail. The plate-girder portion of the structure, the columns, and the method of supporting the girders on the columns are quite unusual. The single-column construction allows of running the steam shovels along the ground so close to the columns that they can clean up the whole ore pile except a small amount of material just at the foot of each column. Thus the trestle is permanent and its length of life should be equal to that of bridges and other steel structures.



PERMANENT STOCK-PILE TRESTLE AT NEGAUNEE MINE SHAFT NO. 3

(Columns, 4-ft. reinforced-concrete cylinders in 1/4-in. steel shells. Girders, cantilever system of 114-ft. spans with 76-ft. suspended spans, 42-in. plate-girders, for 36-in. track gage. Trestle 2591 ft. long, 42 ft. high rail to rail, tracks 20 ft. c. to c. Designed for 10-ton load.)

The columns are 4-ft. cylindrical reinforced-concrete columns with the base enlarged on a taper to a bottom diameter of 6 ft.; they are inclosed in 1/4-in. steel shells, which serve as forms for the concreting as protection to the shaft against damage by the ore and the steam shovel.

*Mr. Elliott recently read a paper describing the trestle, before the Lake Superior Mining Institute. The present article is based on data given in that paper.

Each column rests on an independent base, which is a [illegible] concrete footing [illegible] ft. deep, 12x26 ft., the long dimension transverse to the track. Footing and column are reinforced [illegible] fifty-two [illegible]-in. steel rods, which rise from the base into the shell and are tied at the bottom to [illegible] old rails, running in the long direction of the footing. The rods, [illegible] 20 ft. above ground, and spaced by several rings, continue to the top, [illegible] ft. above ground. The shells are strongly anchor-bolted to the footing. At the top the concrete of the column is rounded and smoothed off with a rich mixture to prevent entrance of water between concrete and shell.

The columns are 114 ft. apart, center to center. This great length of span for the light load (10 tons moving load) and the correspondingly shallow girders is made feasible by the use of cantilever span construction. A [illegible]-ft. girder section at the column is connected with bracket support to the column and forms the fixed span, while the [illegible]-ft. intermediate portion forms the suspended span. Each girder is a latticed box section, 30 in. wide, of which each half is a [illegible] channel 12 in. deep, with [illegible]-in. web-plate, flanges turned in.

The construction for supporting the girders on the columns is a framework in the shape of an inverted square pyramid, comprising four bracket struts extending out at angle of 45° from the columns and transverse and diagonal top ties of [illegible]-in. channel. There is also a cross-tie in the middle of each suspended span.

The girders carry 5 in. sawed ties [illegible] ft. long, on which is laid the 40-lb. rail. Bolted to the under side of the ties, and immediately outside of the two girder web-plates, are two 4x4-in. longitudinal timbers, which prevent transverse shifting of the track.

The cost of the entire trestle (2591 ft. long) was $51,[illegible] or $[illegible] per lin. ft. erected, including decking, ties, walks, rails, etc. Of this total, the steel girder construction and the column shells (and trestle [illegible] in the middle portion, which is of more normal construction) amounted to $[illegible],100, or $[illegible] per ft.

Comparing the trestle with a wooden trestle in point of cost, including maintenance and accumulated interest, the following facts are discovered: The greater first cost of the steel trestle is paid back [illegible] (by the saving in maintenance, i.e., annual demolition and renewal and repairs) in [illegible] years, the average life of the wooden trestle. For any longer period than [illegible] years, the steel trestle shows a marked financial advantage, because of the renewal cost of the wooden structure, so that at the end of 20 years a saving of $[illegible] is realized. Should the mine continue productive beyond the 20 years and the steel trestle still be in good shape, the saving would continue to grow.

Quarry Accidents in the United States during 1913 [illegible] [illegible]

An Instance of Lightning on a Steel Dome and Reinforced-Concrete Walls

Numerous requests have been received for specific information as to the performance of reinforced-concrete structures subjected to the play of lightning, but below are the first complete and accurate observations that have been put on record. They are reported in a letter of C. D. Perrine, of the Argentine National Observatory, at Cordoba, published in *Science*, Oct. 9, 1914. It is evident that the domes and reinforcing were carefully grounded to lead lightning discharges safely to ground. Freedom from disturbances within the domes was expected as the construction was most favorable for such protection.

The center of the storm, judging from the clouds and their motions, was not over [illegible] mile south [illegible] of the observatory. In nearly all the storms which I had seen here previously the discharges were nearly all between clouds. (Perhaps because most of them occur at night?) In this storm nearly all of the discharges were between the clouds and earth.

The direction of motion of this storm, as is usually the case, was from south to north. After some half dozen discharges close to the south there was a heavy one to the northwest about three hundred meters away, then another to the northeast about the same distance.

On account of this being a heavy storm and apparently passing directly over us, I was interested to see what the effect would be on our two new reinforced-concrete walls and steel domes sheathed with galvanized iron, and was outside among the central group of buildings [illegible] ft. from the domes in question, one of them in full sight.

A minute or two after the flash to the northeast, mentioned above, there was a general illumination close by, followed almost instantly by the ripping sound of a very close stroke. The interval between the flash and the sound was certainly not over [illegible] second. To me the sound appeared to be made up of three or four separate discharges [illegible] not consecutive.

The power and light currents were cut off until about [illegible] p.m., when it was found that fuses had been blown on our lines (which were special lines) just outside the [illegible] station, some [illegible] meters away. No other effects of the [illegible] were noticed in or near this station.

The dome which had just been completed was largely out of sight from where I stood and no one at the observatory seems to have seen the actual flash. A [illegible], however, in the grounds of the Meteorological office about [illegible] meters away, had a full view of both domes and buildings, was facing them and saw the flash just over and about the new dome. This [illegible] well with the direction and distance from the point of observation.

After hearing of this observation I made a careful examination of the dome and in particular the connection of the copper cable with the track upon which the dome revolves, which forms the connection between the metal dome and one of the vertical I-beams embedded in the concrete for grounding the circuit. The lightning rod proper extends about [illegible] meters above the highest part of the dome and terminates in a bunch of brass wires. No signs whatever of any [illegible] have been found at any point about the dome.

[illegible]

[illegible]

the lightning rod and then the whole surface of the metallic dome appeared to be covered with sparks or flashes.

It seems certain, therefore, that the dome was actually the principal point of discharge for a fairly heavy flash of lightning. (It is uncertain how much of the discharge was taken by the derrick, but it would appear to have been relatively small.) Also the induced currents in the light and power lines were sufficiently heavy to blow the fuses in both.

At the time the bolt struck, there was a peon inside the closed dome, cleaning the running-gear. When questioned he said he had felt nothing nor had he noticed anything unusual beyond the heavy noise.

This experience seems to be a fairly severe test for such a construction—a metallic dome surmounting concrete walls which are heavily reinforced with iron—the metal in the walls having a good ground connection and being connected also with the dome.

Failure of the Reinforced-Concrete Customs House at La Ceiba, Honduras, C. A.

In Engineering News, Sept. 17, 1914, p. 607, there was printed a brief note recounting the failure of a roof slab in the reinforced-concrete Customs House under construction at La Ceiba, Honduras, in which five men were killed, including the designer of the building, who was an American. Since then we have received from F. J. Parmele, Assistant Engineer, Vaccaro Bros., of La Ceiba, an account of the failure.

The building was being erected for the Honduras government by a contracting firm, which was also the designer of the structure, plans for which were accepted without verification by the government, and the construction for which was carried on without governmental inspection. The building was an extremely simple structure, 124x108 ft. in plan, with one story over the whole area 20 ft. high, and a second story over part of the area 12 ft. high. The main structural elements in the design were square columns 12x12 in. in section, reinforced with corner rods, and spaced on the corner of the bays 20x24 ft. $3\frac{1}{2}$ in. The long dimension of the bay was spanned by 9x12-in. beams reinforced with five $\frac{1}{2}$-in. and two $\frac{3}{8}$-in. rods bent up over the columns and lightly stirruped. The roof of the first floor, which also formed the floor for the second floor in the two-story portion, was a 6-in. floor slab spanning the 20-ft. bay between beams, reinforced with $\frac{1}{2}$-in. bars 12 in. c. to c., 2 in. from the bottom of the slab. The second-story portion was disposed as to columns or partitions without apparent regard to the supporting columns beneath, a decidedly poor feature of design, but one which apparently did not cause failure, as the collapse occurred in the one-story portion of the building.

The failure took place immediately after the removal of the forms under the roof of the one-story portion, and covered an area of about 50x60 ft. It was found after the failure occurred that the plans had not been followed in several respects, notably in the thickness of the roof slabs and in the design of the columns. As is shown by one of the columns, in the accompanying view, which is taken from the second story looking down into the hole made by the collapse, the columns were built in a very curious fashion. Instead of the straight 12x12-in. section through their entire height of 20 ft., they were made 24x24 in. in section for a height of 15 ft., and then were off-set to a 12-in. square for the remaining height of 5 ft. to the beams. The reinforcement throughout was of the designed $4\frac{1}{2}$-in. twisted steel bars, wired together by 12-in. spacers.

The roof, which was intended to act as a floor at a future date, as stated above, was supposed to be 6 in. deep. The contractor had no roofing material to bring the surface of the roof up to the proper draining grade, so he added 7 in. of concrete at the high end of the roof; then covered the whole with a light metal lath, and added a top dressing 1 in. thick, making a total depth of 14 in. at one end of the roof, reducing to 6 in. at the corner. The reinforcing, however, was the same as though it had been a 6-in. roof. The initial failure occurred under the thickest section of the roof slab.

In addition to the poor design, the method of construction was not up to standard. The mix was very lean, being about 1 part of cement to 8 parts sea sand, which carried about 10% gravel. In portions of the débris, Mr. Parmele states that he discovered charcoal, broken glass, machetes and nails, all of which was part of débris left from the burning of a building which had previously occupied the site. The method of placing the forms was neither good nor economical. They were, for the most part, made of lap siding, very poorly put together, so the great portion of cement and water escaped. The centering had buckled in several places, causing sags and cracks.

Looking Down into Hole Left by Collapse of Roof of Customs House at La Ceiba, Honduras

(Note column in right foreground.)

The government has placed an embargo on seven other contracts held by the same contractor. Investigation has shown that other buildings under construction by the contractor were equally bad in design and construction.

The New York Rapid Transit Railway Extensions*

By F. Lavis[1]

IV--Design of Structure and Track

Loadings—The subway and elevated structures are all designed in accordance with the specifications for assumed loadings, and strengths of materials and methods of calculation, as given in detail in a paper presented to the American Society of Civil Engineers by Henry B. Seaman, formerly Chief Engineer of the Public Service Commission, and under whose direction they were worked out (Trans. Am. Soc. C. E., Vol. LXXV, p. 313). The principal provisions governing the design for steel structures are given below:

The railroad trains on bridges shall be estimated as required by specifications of railroad company.

Elevated or subway trains shall be estimated as a continuous load of [illegible] lb. ([illegible]k) per lineal foot of each track, or a single local concentration of two adjacent motor trucks with axle loads spaced as follows:

Trolley cars shall be estimated as continuous at 1500 lb. ([illegible]) per lineal foot of each track, or as a local concentration of one [illegible] car with axle loads spaced as follows: (Note: the [illegible] cars are special cars used by the B. R. T. for [illegible].)

The roadway for trolley cars on bridges shall be assumed to be 12 ft. wide and shall be capable of carrying the loads specified for roadway of bridges.

The roadway load for bridges shall consist of a uniform load of 12[illegible] lb. per sq.ft. of surface, or a local concentration of [illegible] on one axle with a wheel gage of [illegible] ft. This load may be assumed to cover a space of 12 ft. wide by 1[illegible] ft. long.

The roadway load over subways shall consist of a uniform load of [illegible] lb. per sq.ft. of surface, or a single local concentration of [illegible] on four wheels, 12 ft. between axles and [illegible] ft. wide. These concentrated loads shall be assumed to be distributed over an area of 2x2 ft. on the pavement and thence through the earth at a slope of [illegible] to [illegible]. [illegible] shall be assumed to be loaded at [illegible] lb. per sq.ft.

[illegible] shall be estimated as loaded at [illegible] lb. per sq.ft. of surface. [illegible] platforms shall be estimated as loaded at [illegible] lb. per sq.ft. of surface.

[illegible]

[illegible]

*[illegible]

[1][illegible]

No increase shall be made for impact to horizontal loading (centrifugal or traction forces).

Wind—Provision shall be made for wind pressure acting in either direction, horizontally, of 3[illegible] lb. per sq.ft.

Traction—Provision shall be made for the sudden starting or stopping of a train [illegible] ft. in length, estimating the coefficient of sliding friction at [illegible].

Temperature—Provision shall be made on bridges for a variation in temperature at 1[illegible]° F. [illegible] difference of [illegible]° in the temperature of the chords of the same truss, or in that of adjacent trusses of the same structure shall be considered in spans of more than 3[illegible] ft.

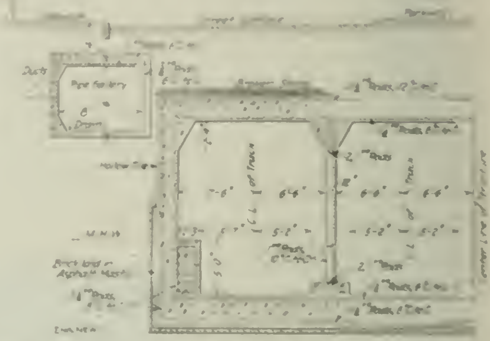


Fig. 10. Half Section of B. R. T. Subway on Fourth Ave., Brooklyn, Built in Reinforced Concrete with Pipe Gallery under Sidewalk

The following table shows the unit stresses (1 k = 1000 lb.) allowed for steel used in the structure taken in conjunction with the foregoing loadings.

Nature of stress	Steel Medium Structural	Cast
Tension (Net)	20k	[illegible]
Compression (l/D [illegible]) [illegible]	2[illegible]	[illegible]
Compression (12 D[illegible]) [illegible]	16.5k	
Compression [illegible]	$\frac{20k^*}{1 + \frac{[illegible]}{[illegible]}}$	
Bending [illegible]	[illegible]	
Bending [illegible] Rivets and [illegible]	[illegible]	
Shear [illegible] (Net)	[illegible]	[illegible]
Bearing [illegible]	[illegible]	
Bearing [illegible] per lineal in.	[illegible]	

l = Length of [illegible] in inches.
r = Least radius of gyration [illegible] in inches.
D = Diameter [illegible] in inches.

*Note: Compression members in steel [illegible] shall not receive greater unit stress than that allowed for 1[illegible] [illegible].

When [illegible] are [illegible] the [illegible] will be assumed to take 2[illegible] of the loading.

[illegible] excess will be added [illegible] number of rivets required [illegible] [illegible].

Preliminary Investigations

Extensive borings, [illegible], were taken before construction to determine as nearly as possible the character of the subsoil, depth to rock, etc., although the latter is extremely irregular. All existing structures both above and below ground, were located as well as possible so that proper provision might be made for taking care of them, though the actual final disposition of [illegible] of the small pipes, etc., was not determined until they

were all uncovered by the excavation and accurately located.

General Design

Speaking generally, the present designs are based on the use of structural-steel frames with concrete jack arches between. The use of reinforced concrete is very limited. It seems to be generally considered that the use of the structural-steel frame greatly facilitates the support of the street decking during construction, because just as soon as a bent is set up and riveted, the load may be transferred to it.

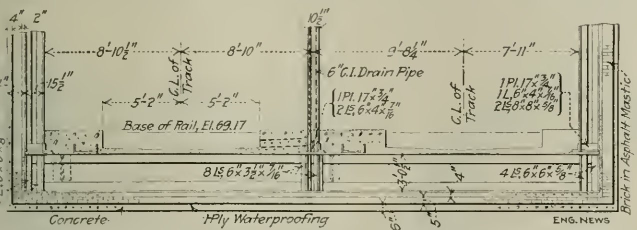

Fig. 11. B. R. T. Subway on Broadway at Canal St., Showing Very Heavy Floor to Resist Upward Pressure of Water

Under the requirement, that the street surfaces shall be maintained and their use for vehicular and other traffic be uninterrupted, it is generally necessary, on account of the width of the excavation, to carry this decking on timber supports, which, as will be seen later, fill up a large part of the excavated space. The construction of reinforced-concrete structures under these conditions is, therefore, somewhat difficult and liable to be patchy, but by proper care in arranging the timbering, the steel-framed bents can be erected easily.

The usual members employed in the steel-frame type of construction in these subways are small enough to be easily handled, so that reinforced concrete has little advantage in the use of small construction units. The ease of construction of the steel-frame structure, and advantages of support more than outweigh any disadvantage in the necessity of using skilled steel erectors, as against the supposed ability to use unskilled labor for reinforced concrete, even though the form work for the concrete with the steel structure is little less than it would be for ordinary reinforced concrete. Fig. 10 shows the reinforced-concrete design adopted in 1908 for the 4th Ave., Brooklyn, lines, which, however, were built mostly in open cut.

The use of the specially rolled "bulb" angles, used on the original subway, has been abandoned and only standard steel shapes are used. Usually the columns rest directly on the concrete, as shown in in the normal sections, Fig. 8, but in certain places I-beam grillages are provided. No stone-block footings are used. Where the ground is soft or where water pressure exists, specially designed floors are necessary. One of the most important of these places is at Canal St., where the subgrade of the lower level is 40 ft. below M. H. W. or normal ground-water level. The heavy girders and thick concrete floor required at this point is shown in Fig. 11. A typical floor to meet conditions below ground-water level is shown in Fig. 15, which is a cross-section of part of the Lexington Ave. subway, where the line passes over what seems to have been an old swamp. This special type was designed principally for the purpose of carrying the structure on the soft ground. Just north of this, at Lexington Ave. and 128th St., where the subgrade is considerably below the water level, a typical design (Fig. 16) of reinforced concrete, for resistance to water pressure in rock, is used.

On account of the fact that the New York rock, a micaceous gneiss, is well known to present difficulties of support, that is, on account of bad seams, etc., to be "heavy" in places, it was decided to use a reinforced-concrete lining for the deep-level tunnels under Lexington Ave. It was found on opening up the work, however, that the necessary temporary supports of timber made this type of construction difficult to execute satisfactorily, and a change was, therefore, made to the design shown in Fig. 13. This, as will be seen, permits the construction of the center wall and the haunches with the steel columns and longitudinal I-beams, so that a direct center support can be built to the roof, which is generally sufficient for

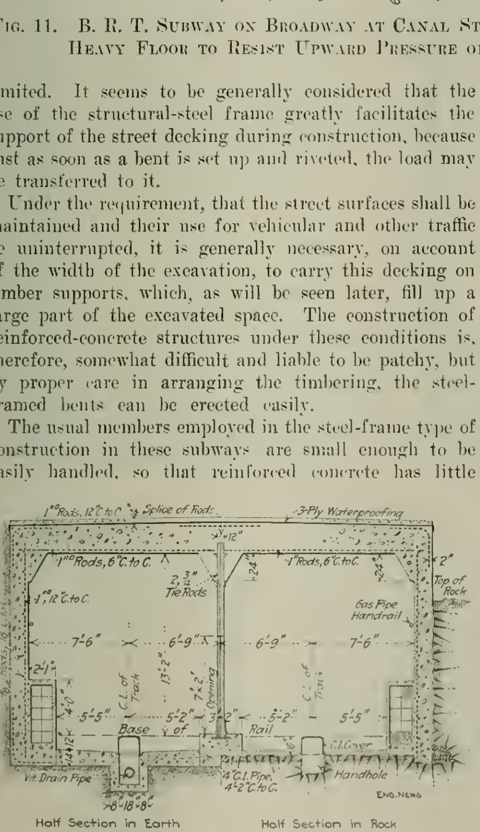

Fig. 12. Reinforced-Concrete Subway on Lexington Ave.

(This shows the upper level. The tracks on the lower level are in tunnel with a roof of two arches supported on a center wall and the sidewalls.)

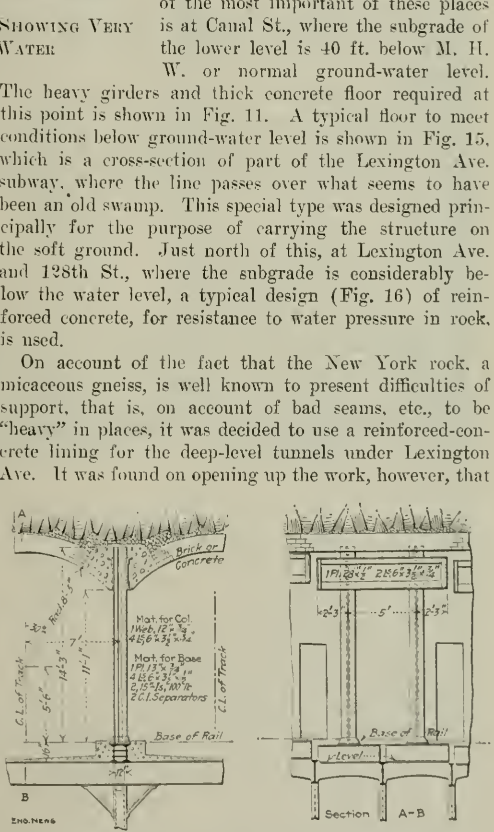

Fig. 13. Alternative Design for Center Wall Using Structural Steel Instead of Reinforced Concrete

[illegible] the construction of the concrete arches.

The [illegible] character of the rock and the variation [illegible] changes in the [illegible] necessary to shift [illegible]

[illegible] of operation, a third party might be found, and as there then seemed to be a possibility that this might be one of the existing steam railroad lines, it was decided to provide clearance for standard railroad equipment and the designs of these two sections were modified accordingly to provide this. As all doubt in regard to the future operation has, however, been eliminated, it has not been thought necessary in the design of the new

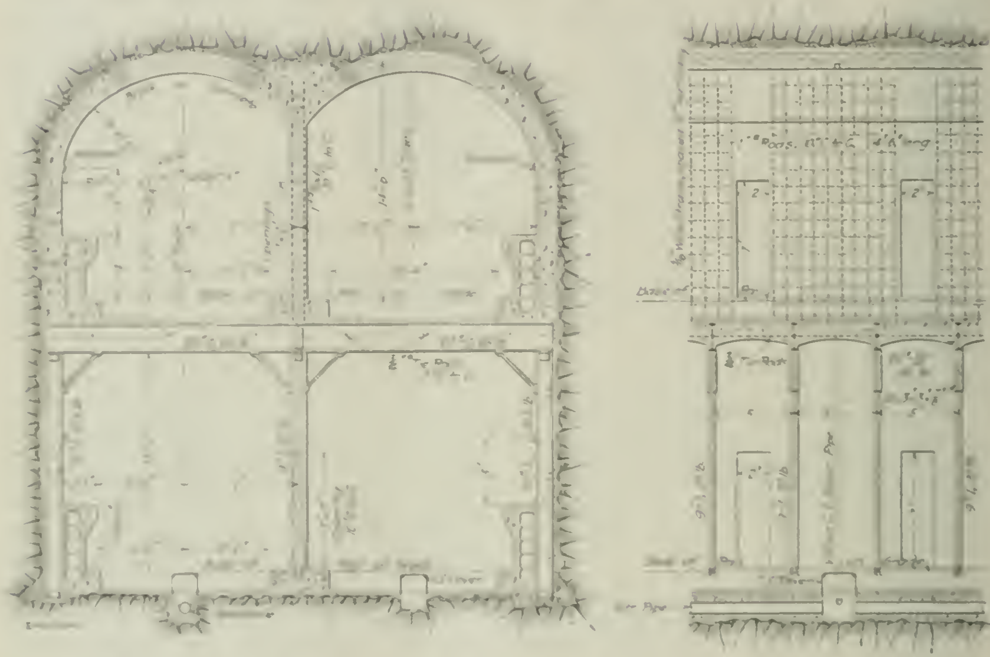

FIG. 11. DOUBLE-DECK SUBWAY ON LEXINGTON AVENUE BUILT WHOLLY IN TUNNEL

[illegible] The heavy ground [illegible] Lexington Ave. [illegible] Fig. [illegible]

[illegible] such as the Harlem River Tubes, [illegible]

[illegible] During the early days of the Public Service Commission [illegible]

lines now to be built to provide for larger equipment than it is known will be used, and the clearances decided on for the new lines are only slightly larger than those provided in the present subway, as is shown in the following table, and in more detail in the typical cross-sections which are shown.

In Fig. 8 (of the previous article) is shown a cross-section of the 7th Ave. line of the Interborough, which is the minimum section for the new lines. Figs. 12 and

FIG. 13. [illegible] SECTION 12 OF [illegible]

14 show the Lexington Ave. line, which is to be operated by the Interborough, but which was designed before the question of operation was definitely decided. Fig. 11 shows the cross-section of the Broadway 59th St. route of the B. R. T. The following table shows a general comparison of the dimensions of the original subway and those since adopted.

	Height above top of rail	Width*
Original subway	12 ft. 4 in.	12 ft. 6 in.
Fourth Ave. Brooklyn and Centre St. loop	14 ft. 6 in.	14 ft. 0 in.
New subways:		
B. R. T.	12 ft. 8 in.	14 ft. 3 in. & 13 ft. 6 in.
Interborough	12 ft. 3 in.	13 ft. 6 in. & 13 ft. 0 in.

*From center of columns between tracks to face of side wall. (Columns about 8 in.)

Note—These are dimensions on tangents and are increased on curves to provide equivalent clearance.

Cross-sectional dimensions of other rapid transit subways in the United States are approximately as follows, there being many minor variations:

	Height above top of rail	Clear width
Boston, Tremont St., 1898	13 ft. 10 in.	12 ft.
Boston, Washington St., 1905	14 ft. 5 in.	12 ft. 2 in.
Cambridge, 1910	14 ft. 9 in.	12 ft. 6 in. (a)
Philadelphia, 1907	14 ft.	12 ft.
H. & M., 6th Ave., 1908	12 ft. 10 in.	13 ft. (b)

Note (a)—The Cambridge subway is large enough to take standard steam railway equipment, the tracks are 12 ft. on centers.

Note (b)—Sidewalk over duct bench at side.

The question of cross-section is one of considerable importance. It is determined largely by the size of the cars, the economic limit of which is controlled largely

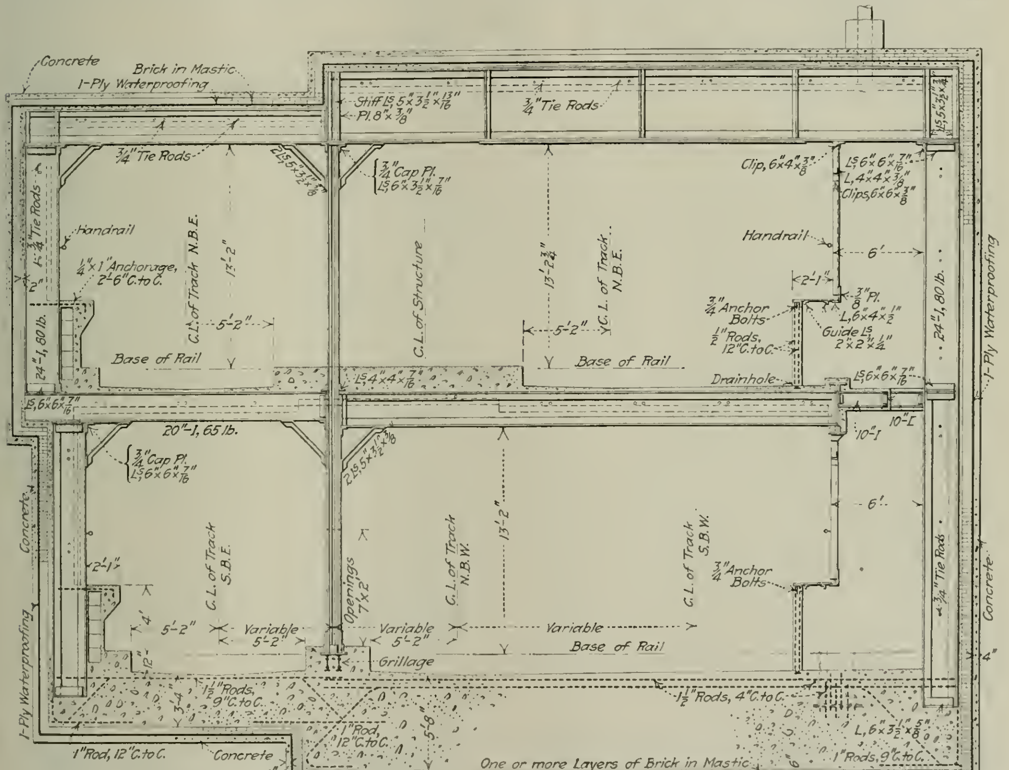

FIG. 16. LEXINGTON AVE. SUBWAY AT 129TH ST. DOUBLE-DECK STEEL-FRAME CONSTRUCTION WITH HEAVY REINFORCED-CONCRETE FLOOR

As is shown on the various cross-sections, provision is made for building the conduits for the electric wires, in a side-bench wall with a walk on the top, instead of placing them in the sidewalls, as in the old subway.

The standard track spacing for four-track subways finally adopted is as follows; from the center line of the four tracks to face of sidewalls:

INTERBOROUGH 6'-9" 12'-6" 7'-3"

B.R.T. 6'-9" 13'-6" 7'-6"

Center line Sidewall

by the time necessary to load and unload them at express stations during the rush hours. Under present operating conditions, the spacing of trains is determined probably as much by the length of station stops as by ability to run the trains more closely together between stations. It is probably difficult to determine the exact economic dimensions of a car which will hold the maximum number of people and at the same time permit the minimum time of stopping. As has already been pointed out, the B. R. T. has decided to use a larger car, but the Interborough will probably of necessity be obliged to

[illegible] the use of equipment interchangeable with that [illegible], and therefore all new lines which are to be [illegible] to this latter company, are designed [illegible] slightly larger than that now in use.

FIG. 17. HEAVY STEEL SECTIONS IN CENTER WALL LEXINGTON AVE. LINE AT 59TH ST.

The cross-section has also, of course, an important bearing on the question of ventilation. This, however, is discussed more fully under that heading.

On some of the routes when the designs were made and construction started, it was uncertain whether they were to be operated by the B. R. T. or the Interborough; provision was, therefore, made as is shown in the sketch, Fig. 18, for an adjustable edge to the platforms, so that either the 9-ft. Interborough or 10-ft. B. R. T. cars could be used.

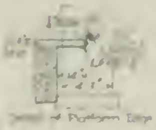

FIG. 18. DETAIL OF ADJUSTABLE PLATFORM EDGE

TRACK CONSTRUCTION—A standard track construction has been adopted for all the new lines, by conference and agreement between the two operating companies and the Public Service Commission. Rails are to be 100-lb. [illegible] sections of the Am. Ry. Eng. Assoc. [illegible]

[illegible]

[illegible]

high cost of track work under the extremely heavy traffic and in the confined space in the subways.

At stations, in order to facilitate cleanliness and sanitation, a special type of track construction similar to that used in the Pennsylvania terminal station in New York* and the Detroit River tunnels† is to be used. A cross-section is shown in Fig. 19.

The track material is to be bought by the Public Service Commission under contracts and at unit prices to be bid for the various items required; it is to be stored and issued on requisition to the operating companies who will install the track as part of the "equipment."

TRACK LAYOUTS—The arrangement of tracks at junction points, so as to avoid crossings at grade, with the consequent delay, as well as danger, has been the subject of considerable thought and study. In the present subway there are three junction points, at Bowling Green, City Hall, and at 96th St. The first two being merely junctions of double-track lines, where only one class of trains, either local or express, has to be cared for on each route, did not present any particular difficulty, it being only necessary to depress one track under the other two. At 96th St., however, where two double-track lines come together into a four-track section, and where express and local trains have to be directed from any one line to any of the others (in the same direction), the problem is more complicated.

The present layout at 96th St. is shown diagrammatically at D, Fig. 20. It will be noted that the switches and slip-crossings are all on the north side of the station, and that as trains from either branch [illegible]

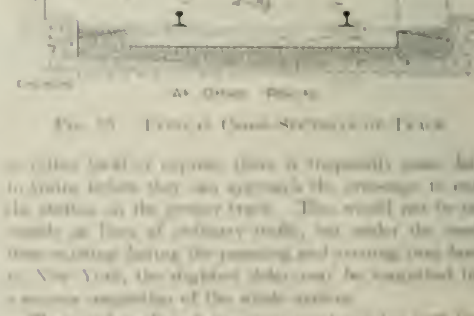

FIG. 19. TYPICAL CROSS-SECTIONS OF TRACK

as either local or express, there is frequently some delay to trains before they can approach the crossings to enter the station on the proper track. This would not be [illegible] on lines of ordinary traffic, but under the conditions existing during the morning and evening rush hours in New York, the slightest delay may be magnified into a serious congestion of the whole system.

The number of such junction points on the new lines has been considerably increased and typical methods of

*"Eng. News," [illegible] Vol. LXIII, p. [illegible]
†"Eng. News," [illegible] Vol. LXXIV, p. [illegible]

overcoming the difficulties are shown in the three diagrams *A*, *B* and *C* of Fig. 20.

So far as possible in all the designs for the new lines the engineers have tried to avoid any slow points, such as switches, crossings, etc., at places other than close to stations where trains must stop, and to locate them on the *farther side* rather than on the near side where they would be reached before the train enters the station, and where in case the line is not clear the train would have to make a signal stop before reaching the switch as well as the station stop after.

The diagram at A shows the track layout at 125th St. on the Lexington Ave. line. It will be noted that coming from the north, trains from either branch reach the station without crossing any switches, are both on the

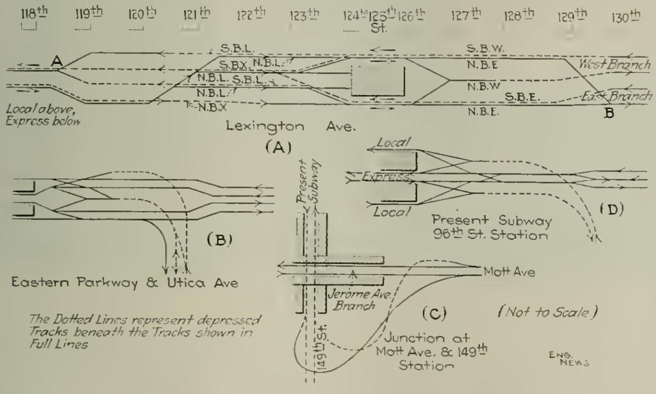

FIG. 20. VARIOUS TRACK INTERSECTIONS

same level and on their same respective sides of the station. Continuing south, those trains which become expresses from this point, pass the required switches within 300 or 400 ft., while the locals have a switch, which is, of course, a slow point, at 119th St. (about 1500 ft. beyond the station). This, however, is of little importance, so far as causing any delay in the south bound movement of the local trains is concerned, as their next station stop is at 116th St.

Coming from the south the expresses reach the upper level in the east side over practically a straight line with no switches, with just enough ascending grade to slow them down. Leaving, they take one or two switches as they are diverted to either the east or west branch, but both within 300 ft. of the station. The locals coming from the south have one or more switches to pass before they reach the station; this, however, is not of importance especially as they do not anywhere come in contact with the expresses. As may be seen these latter switches are not necessary for the operation of through trains, as trains from either side of the station going north reach either branch without a crossing of tracks of trains going in the opposite direction, but are put in for convenience, to provide two extra side tracks for any emergencies of operation at this junction.

The other two diagrams are self-explanatory, except to say that at Eastern Parkway and Utica Ave., diagram *B*, the arrangement is not quite so elaborate as there is not expected to be such heavy travel on this section as to warrant large expenditures to prevent short delays.

Effect of Creosoting on Strength of Oregon Fir Piling

The August, 1914, bulletin of the American Railway Engineering Association is entirely given up to a paper by H. B. Macfarland, Engineer of Tests, Atchison, Topeka & Santa Fé Ry., entitled "Tests of Oregon Fir Piling." The object of the tests was to determine the effect of the steaming process of creosoting as practiced on the Pacific coast upon the physical properties of the piling. Mr. Macfarland states that tests have been made demonstrating that the physical structure of Oregon fir piling is decreased considerably by the boiling process of creosoting, but claims have been made that the steam creosoting plant did not deteriorate the physical strength of the material except possibly on the outer surface. These statements have been based on a small number of small-size tests, so the railway decided to make a large number of tests on both full-size piles and on small pieces cut from piles. The piles to be tested were selected and treated under the observation of the office, and were tested for transverse strength, compression parallel to grain, compression perpendicular to grain, shearing parallel to grain, moisture and creosote absorption. The minor specimens, cut from the creosoted piling, were tested in transverse strength and compression.

The material in treating is subjected to three processes, namely, steaming, removing the moisture and filling with creosote.

When introduced into the tank the logs are thoroughly wet as they come from salt water. They are brought to a temperature of about 330° in a period of one and one-half hours by the introduction of steam. The temperature is maintained for one and one-half hours. A vacuum of about 28 in. is then produced and the temperature reduced to a minimum of 190°. The vacuum process is maintained for 10 hours. The tanks are then filled with oil at 190° temperature and an average pressure of 75 lb. is maintained for a period of five hours, until the piles have taken up the proper quantity of oil. The oil is then transferred from the treating tank to the general storage tank, after which the timbers are removed.

The general conclusions are as follows:

In every case the treated material shows a decided loss of strength as compared to untreated. The greatest loss is in transverse strength due to the influence of treated sap-wood. The loss of compression strength is considerable. The result of the tests indicates the following conclusions relative to the effect of steaming process of creosoted Oregon fir piling: (1) Depth of penetration of creosote was mainly dependent upon the depth of sap-wood; (2) heart-wood of Oregon fir piling was almost impervious to treatment; (3) depth of penetration of creosote was the same in the butts as in the top; (4) depth of penetration of creosote should be interpreted as to mean the depth of active penetration; (5) tests of minor specimens show that injury to fiber through method of treatment is not localized to treated fiber alone, but extends throughout the whole specimen; (6) transverse strength of Oregon fir piling was decreased 42% due to steaming process of creosoting; (7) compressive strength perpendicular to the grain was decreased 32% through the steaming process; (8) compressive strength parallel to the grain was decreased 27%, due to steaming process; (9) in general average, the strength of Oregon fir piling subjected to steaming process of creosoting was only two-thirds its original strength.

Snow Disposal Experiments in Manhattan Borough Sewers

By William Goldsmith*

SYNOPSIS—Besides disposing of [illegible] *of snow by means of the sewers in 1914, the Borough of Manhattan, New York City, made a hundred detailed observations on the sewers receiving the snow. These are presented in tabular form, arranged by size of sewers and giving theoretical velocity of sewage and actual velocity of snow, besides other data.*

The sewers of Manhattan Borough were used to a greater extent for the disposal of snow during the winter of 1914 than in any previous year. Approximately 800,000 cu.yd. of snow were dumped by carts into sewer manholes instead of being hauled to the river front, as is the usual method. [See accompanying views of (1) hauling, (2) shoveling and (3) dumping snow into sewer manhole and (4) dumping at waterfront.]. Every facility of the Manhattan Bureau of Sewers was offered to the Street Cleaning Department in order to expedite the removal of snow.

In order to determine to what extent the sewers of Manhattan Borough could be used for snow removal, a series of experiments were conducted during the winter of 1914. The experiments may be divided into five parts:

(1) Obtaining the actual weight of snow.
(2) Noting the effect of sewer water on snow.
(3) Noting the effect of dumping snow into sewer siphons.
(4) Noting the effect of dumping snow into sewers of different sizes and velocities.
(5) Costs.

Weight of Snow

From the "American Engineer's Handbook" we find that freshly fallen snow weighs from 5 to 12 lb. per cu.ft. Compacted or wet snow weighs from 15 to 50 lb. per cu.ft.

By an actual test it was found that compacted snow as carried in wagon loads during 1914 weighed 36 lb. per cu.ft. This last weight was obtained by test on an average sized New York wagon into which snow was shoveled. This does not give the actual weight of a compacted cubic foot, but is the cubic foot which includes voids as they exist in the average wagon load. The test [illegible] this weight was made on March 2 [illegible] average wagon load being weighed on an ordinary coal scale. The snow which was shoveled into the wagon consisted of chunks about [illegible] in. and weighed from [illegible] lb. per piece. The atmospheric temperature was about [illegible]° F. The weight of the wagon and snow was [illegible] lb.; of the wagon empty, [illegible]; of the snow, therefore, [illegible]. The cart carried [illegible] cu.yd. of snow, thus giving [illegible] lb. as the weight of a cubic yard of snow in the wagon. This weight is used as a basis in what follows.

Effect of Sewer Water on Snow

In order to determine how quickly snow melts when it comes into contact with sewer water, an actual test was made in the Manhattan Ave. sewer between [illegible] and [illegible] streets. A cake of snow well compacted was weighed, dropped into one sewer manhole, picked up by a man at the next manhole and re-weighed. The temperature of the water in the sewer was 60° F.; depth of water, 12 in.; size of sewer, 5x4 ft.; velocity, approximately 3 ft. per sec.; distance between manholes, 250 ft.; time for snow to travel from one manhole to the next, 85 sec. Three separate cakes of snow were dropped at intervals of approximately five minutes, the test resulting as follows:

Weight of snow before being dropped into manhole	Weight of snow when picked up at second manhole
8 lb. 7 oz.	6 oz.
9 lb. 8 oz.	11 oz.
13 lb.	1 lb. 1 oz.

By a simple proportion we have:

Actual distance between manholes : distance necessary to melt snow :: lost weight : total weight.

This gives 262 ft. as the point where the first piece of snow would be entirely melted; 269 ft. for the second, and 272 ft. for the third. From this, it may be safely assumed that within 300 ft. no snow would be left.

There is a possible inaccuracy in the above simple proportion for the reason that as the snow is melted the mass becomes smaller and the area in contact with the sewer water is diminished.

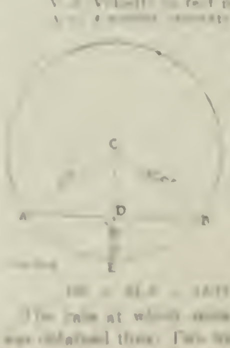
The compacted snow used in this test was the largest which could be obtained, it having laid on the streets for nearly a month, and was more like ice than snow. Thus, this was a more severe test than would have been the case had freshly fallen snow been used.

Lenox Avenue Sewer Experiment—To determine to what extent the temperature of sewer water was affected by the continual dumping of snow therein, and whether, theoretically, there was sufficient heat present to melt the snow, an experiment was tried on the Lenox Avenue sewer between 114th and 115th streets, thus:

Size of sewer, [illegible] ft. circular.
Depth of water, 9 [illegible] in.
Velocity (actual), 2.4 ft. per sec.
Temperature of sewer water, [illegible]° F.
Temperature of sewer water below point of snow dumping, [illegible]° F.

$$Q = AV$$

Q = Cu.ft. of water passing [illegible] per sec.
A = Area of water section in sq.ft.
V = Velocity in feet per sec.
A = [illegible]



[illegible]

The rate at which snow was dumped into this sewer was obtained thus: Two wagon loads were dumped beside the manhole; [illegible] took just eight minutes to

*[illegible]

Figs. 1-4. Snow Disposal into Sewers and at Water Front, New York City

(1) Hauling the snow to a sewer manhole. (2) Shoveling snow into manhole. (3) Dumping snow directly into sewer manhole. (4) How snow is dumped at the water front.

shovel it all into the sewer. So we have two wagon loads $\times$ 3550 lb. (previous test) = 7100 lb. shoveled into the sewer in eight minutes, giving a rate of 888 lb. of snow entering the sewer per min.

It takes 144 B.t.u. to change 1 lb. of snow or ice into water; therefore, $888 \times 144 = 127{,}782$ B.t.u. would be required for these 888 lb. per min.

The temperature of snow is approximately 32° F.; the sewer water was 60° F., which is 28° above that of the snow.

Since 18,750 lb. of water passes per min., we get $18{,}750 \times 28 = 525{,}000$ B.t.u. available to melt this snow; whereas, it is shown above that only 127,872 B.t.u. are necessary.

A man standing in the sewer 127 ft. from where the snow was dumped, found the sewer-water temperature to be an average of 54° F., giving a drop of 6° from the normal temperature of the water. This gives a theoretical expenditure of $18{,}750$ lb. $\times$ 6° = 112,500 B.t.u., which is slightly less than the theoretical 127,872 B.t.u. necessary for the entire melting of the snow. It was observed, however, that a few small pieces of snow were still intact at this point, which explains the reason for this theoretical figure.

At a manhole 261 ft. from the dumping point no snow remained, but the temperature of the water was normal; i.e., 60° F. This experiment shows that there was almost four times as much heat in this sewer as is needed to melt all the snow dumped therein, within 200 ft., and the theoretical amount of heat used in melting the snow checks up the actual amount very closely, showing that gases and chemical combinations must not be considered in this connection.

Eighty-First Street Sewer Experiment — More snow was dumped into the 81st St. sewer between Broadway and West End Ave., during March, 1914, than into any other sewer. This is a 6-ft. circular sewer and had 16 in. of water flowing in it on March 15, with a velocity of 4 ft. per sec. On this day 640 loads of snow were dumped into three manholes within this block during eight hours. This gives 5 cu.yd. per min. of snow dumped into the sewer. Five men were used at each manhole to shovel the snow dumped from the carts. A quick test at one of these holes showed that it took 30 sec. to empty a load containing 4 cu.yd. into the sewer, this giving 32 sec. per cu.yd., which is the quickest record obtained throughout these experiments and indicates a probable limit with which it is possible to empty snow into the sewer manholes.

This sewer turns south on Riverside Drive and enters the Hudson River at 80th St., a distance of approximately 1000 ft. Observations made at this outlet while the snow was being dumped into the manhole at the maximum rate showed no indication of snow at this point.

Tidal Sewer Experiments—Many sewers in Manhattan Borough are affected by the tides; that is, the water rises in them with the incoming tide and is entirely clear of tidal water when the tides are low. Some of these were used for snow removal, but it was found that some clogged up and that the snow did not melt, but would come out at the outlet in large chunks. This was probably due to the low temperature of the tide water bringing the sewage temperature much lower than is ordinarily the case. These observations would indicate that sewers affected by the tides cannot be used to advantage at all times.

Tests of Siphon Sewers

At 106th and 110th Sts. are sewers which are interrupted by the Lexington Ave. subway. At these points siphons were constructed by the Public Service Commission, and it was thought that these might clog up if snow was dumped into the sewers above the siphon points.

At 110th St., 117 ft. west of the west curb line of Lexington Ave., there is a manhole which is practically the start of the siphon underneath the subway. At this point 23 men dumped snow into the sewer as quickly as possible. (This is a more severe test than a wagon dumped directly into a manhole.) Most of the snow consisted of large chunks. Observations at a manhole 274 ft. from this point at the other end of the siphon showed practically no trace of snow. Some of the large chunks appeared reduced approximately to one-quarter of their size, but no trouble was found with the working of these siphons. Practically the same results were obtained at the 106th St. siphon, from which may be deduced that sewer siphons of this type, when other conditions are favorable, can be used with perfect safety for the disposal of snow.

Actual Tests on Sewers of Various Sizes and with Different Velocities

In order to lay down some general rules to determine which sewers can be used for the removal of snow, experiments were made on different sized sewers with different velocities at various locations. In making these tests, the following method was used:

One intelligent man with three laborers, with hooks, shovels, electric light, thermometer and rule, was the experimental outfit. Two manhole covers were removed, a man went down one manhole, noted the depth of water, kept his thermometer in the water for approximately one minute, and with an electric light read the temperature. The distance between manholes was then measured and the time recorded which it took a float (small piece of wood) to travel from one manhole to the next. A quantity of snow was then [illegible] quickly shoveled into the manhole and observations made to see whether the sewer clogged or whether the snow was easily carried away. At locations which might be used for dumping wagon loads of snow into the sewer, a wagon load was ordered and a dump test made. If no wagons were available an [illegible] heap of snow was gathered about the manhole by the laborers and quickly shoveled in, so that the conditions obtaining when a wagon load was dumped were secured.

In the table on p. 897, under the heading "Remarks," these expressions are used: shoveling, panning, dumping.

"Shoveling" means the process of shoveling freshly fallen or small pieces of snow into a sewer with care, large lumps not being used, as with these the sewer would clog.

"Panning" means the process of using drag scrapers with a laborer shoving the snow into the manhole, or the drag scrapers with horses attached dumping directly into the sewer.

"Dumping" means the process of dumping wagon loads directly into the sewer manhole.

A statement, as "O. K. for shoveling, panning or dumping" means that it is possible to so use these sewers.

"N. G. for shoveling, panning or dumping" means that it is not possible to so use these sewers.

The experiments shown by the accompanying table were plotted. The results as shown by the accompanying curve (Fig. 5) indicate: (1) that snow can be dumped by wagon loads into sewers carrying 10 cu.ft. per sec. or more; (2) that panning can be employed where sewers have 3 cu.ft. per sec. or more flowing in them

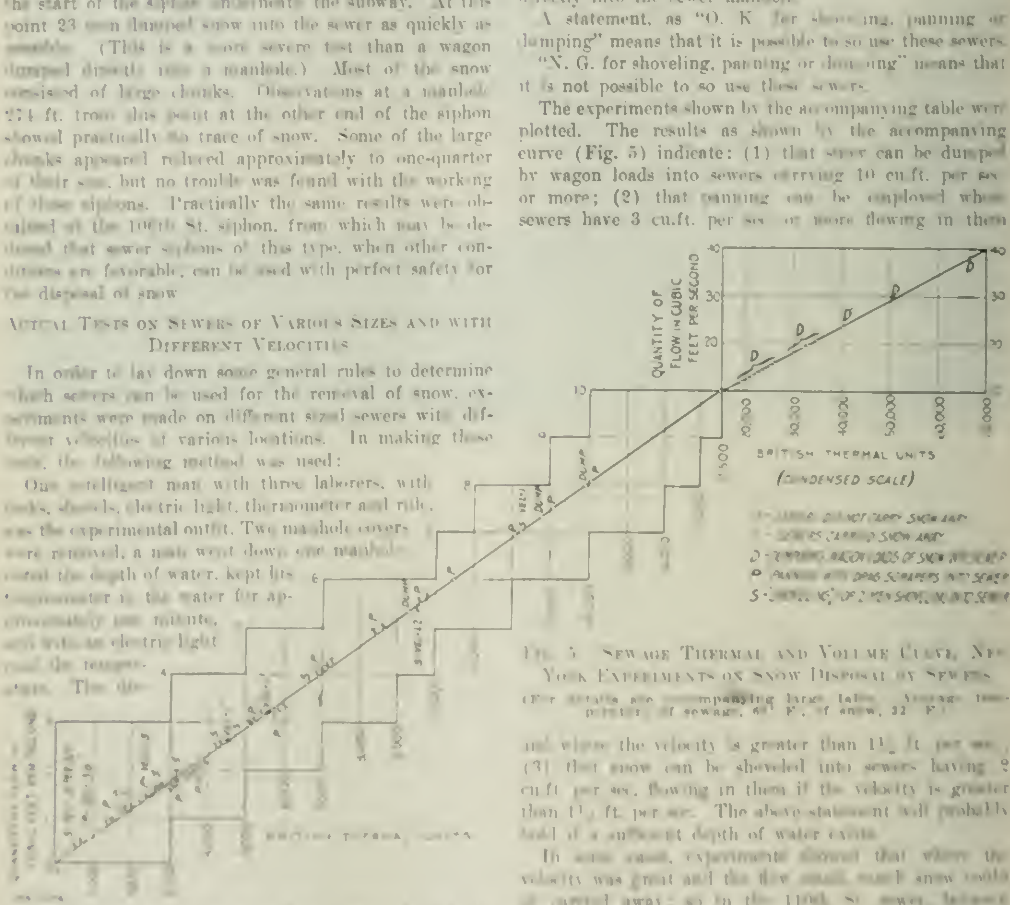


Fig. 5. Sewage Thermal and Volume Curve, New York Experiments on Snow Disposal by Sewers

(For details see accompanying large table. Average temperature of sewage, 60° F., of snow, 32° F.)

and where the velocity is greater than $1\frac{1}{2}$ ft. per sec.; (3) that snow can be shoveled into sewers having 2 cu.ft. per sec. flowing in them if the velocity is greater than $1\frac{1}{2}$ ft. per sec. The above statement will probably hold if a sufficient depth of water exists.

In some cases, experiments showed that where the velocity was great and the flow small, much snow could be carried away; so in the 110th St. sewer, between Madison and Columbus Avenues, we have a flow of 5.2 cu.ft. per sec., the velocity being [illegible] ft. per sec. Yet with this slight flow this sewer makes an excellent dump.

A study of the curve (Fig. 5) will show that the above conclusions are conservative and that sewers outside of these limits may be used, but it is recommended that they should not be unless tried out by actual test in each case.

Costs

Very important items to consider when it is proposed to use sewers for snow disposal are:

(a) Cost of necessary [illegible].

(b) Removal of all [illegible] which are dumped in with the snow.

(c) [illegible] damage [illegible] arising from clogged-up sewers.

OBSERVATIONS TO DETERMINE WHETHER SEWERS COULD BE USED TO REMOVE SNOW IN NEW YORK CITY.

Approximately [illegible] was spent for snow removal from sewers in Manhattan Borough. The inspection cost at sewer manholes was [illegible], approximately, making about [illegible] per cu.yd. of snow dumped. Then, if we assume that [illegible] of snow is dirt or other débris which remains in the sewer or must be removed, we add an additional [illegible] per cu.yd. to the cost, since the removal of dirt in sewers costs approximately [illegible] a cu.yd. in Manhattan Borough. An estimate of damage suits which may result from the use of sewers for disposal of snow is very difficult. This damage would arise from a clogged-up sewer backing sewage into houses, and possible damage caused thereby.

Conclusions

The results and possible deductions from these experiments may be summarized as follows:

(1) Under ordinary conditions, if the flow in a sewer is sufficient to carry the snow away, snow will melt in a sewer within [illegible] ft. from the point where it is dumped (average temperature, [illegible] F.).

(2) The theoretical number of B.t.u. necessary to melt snow is checked by the tests, showing that gases and chemical combinations have little effect and need not be considered.

(3) The maximum rate at which it is possible to dump snow into a sewer manhole 24 in. in diameter is [illegible] cu.yd. per min.

(4) Sewers affected by the tides can only be used to advantage (if other conditions are favorable) when the tide is low.

(5) When other conditions are favorable, siphon sewers will carry snow away just as well as others.

(6) Inspection at each manhole where snow is being dumped is necessary in order that the sewers shall not clog.

(7) Cost of inspection, removal of silt and possible damage suits to be considered before determining whether a sewer should be used for snow disposal.

The consulting engineer of Manhattan Borough is E. P. Goodrich; the engineer in charge of sewers, [illegible]. The experiments described in this article were conducted by the writer, under the supervision of the engineers just named.

A Working Formula for Eccentric Riveted Connections

By [illegible]*

The writer has long felt the lack of a simple formula for the number of rivets required in an eccentric connection, expressed in terms of working quantities. The following is the derivation of such a formula for connections having any number of equal rivet lines.

In Fig. 1, let S_m be the bending stress on the extreme rivet due to the moment WL, S_d the stress on the rivet due to the direct load W, and S_r their resultant, equal to the allowable rivet stress. Resolving [illegible] we have

[illegible]

$$S_m^2 + 2\,S_y S_d + S_d^2 = S_r^2 \qquad (1)$$

If now in Eq. (1) expressions be found for S_m, S_d and S_y involving the number of rivets as an unknown, it can be solved for the unknown. Thus we would have a general expression for the number of rivets required in an eccentrically loaded connection of any number of equal rivet-lines.

The bending stress in the extreme rivet is:

$$S_m = \frac{W\,L\,c}{I_p} \qquad (2)$$

where c is the distance of the extreme rivet from the center of gravity of the rivet-group O, and I_p is the polar moment of inertia of the rivets about O.

To derive I_p directly in terms of the squares of the rivet distances from O is a process both tedious and unnecessary for our final results. But it is a principle of

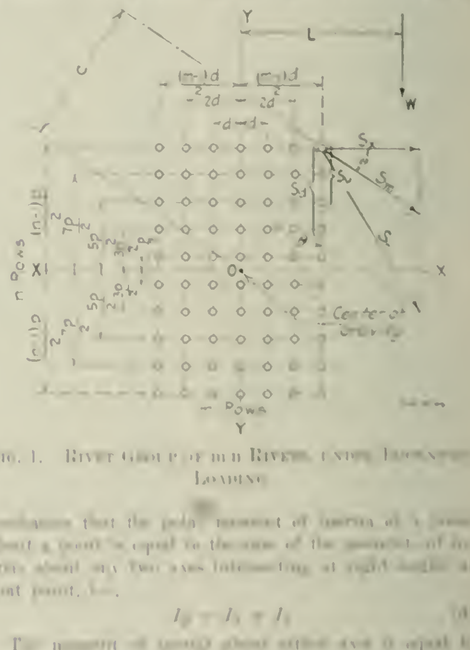

Fig. 1. Rivet Group of mn Rivets, under Eccentric Loading

mechanics that the polar moment of inertia of a plane about a point is equal to the sum of the moments of inertia about any two axes intersecting at right angles at that point, i.e.,

$$I_p = I_x + I_y \qquad (3)$$

The moment of inertia about either axis is equal to the moment of inertia of one of the lines running normal to it times the number of such lines in the group. If n is the number of rivets in a vertical line, p their vertical spacing and m the number of such lines in the group, then (see Note at end of article):

$$I_x = \frac{mn}{12}(n^2 - 1)\,p^2 \qquad (4)$$

Similarly, if d is the distance between vertical rivet lines, or the horizontal rivet spacing, then:

$$I_y = \frac{mn}{12}(m^2 - 1)\,d^2 \qquad (5)$$

Hence Eq. (3) becomes:

$$I_p = \frac{mn}{12}\left[(n^2 - 1)\,p^2 + (m^2 - 1)\,d^2\right] \qquad (6)$$

which is a true formula for the polar moment of inertia of any group of equal rivet lines about their center of gravity.

*[illegible]

If now in the above equation we substitute for $(n^2 - 1)$ its closely approximate value n^2, and similarly m^2 for $(m^2 - 1)$, the modified value of n will not differ from the true value by more than a fraction. Since the value of n is sought to the nearest integer such substitution is valid for all practical purposes. This is also sustained by the satisfactory results obtained from the final formula. The change gives:

$$I_p = \frac{mn}{12}(n^2p^2 + m^2d^2) \qquad (7)$$

Similarly, the true value of c, which is

$$\tfrac{1}{2}\sqrt{(n-1)^2p^2 + (m-1)^2d^2}$$

becomes modified to

$$c = \tfrac{1}{2}\sqrt{n^2p^2 + m^2d^2} \qquad (8)$$

Hence the expression for S_m becomes:

$$S_m = \frac{6WL}{mn\sqrt{n^2p^2 + m^2d^2}} \qquad (9)$$

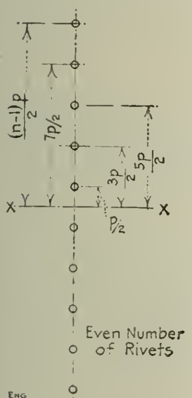

FIG. 2

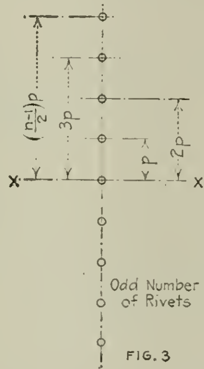

FIG. 3

Since the direction of S_m is normal to c, we have the relation:

$$\frac{S_y}{S_m} = \frac{(m-1)d}{\sqrt{(m-1)^2d^2 + (n-1)^2p^2}}$$

or approximately

$$\frac{md}{\sqrt{n^2p^2 + m^2d^2}}$$

Hence

$$S_y = \frac{6WLd}{n(n^2p^2 + m^2d^2)} \qquad (10)$$

Since the total number of rivets (Fig. 1) equals mn, the direct stress S_d is:

$$S_d = \frac{W}{mn} \qquad (11)$$

Now substituting in Eq. (1) the values for S_m, S_y and S_d, and putting $W/S_r = k$, a coefficient, and reducing it to a most convenient quadratic form, we get:

$$\left[\frac{m^2p^2}{m^4d^2 - k^2p^2}\right]n^4 + n^2 = \frac{(6L + md)^2k^2}{m^4d^2 - k^2p^2} \qquad (12)$$

Solving the above equation first for n^2, then for n, and eliminating in the resulting expression the terms unity (1) under each radical sign, which may be done without affecting the final value of n by more than a fraction as reasoned above, and by proper cancellation, the following convenient working formula is obtained:

$$n = \sqrt{\frac{k(6L + md)}{mp}} \qquad (13)$$

where as a recapitulation:

- n = number of rivets required in each line for any group of equal rivet lines;
- m = number of rivet-lines employed; group of equal rivet-lines;
- L = eccentricity of load;
- p = vertical rivet spacing;
- d = horizontal rivet spacing, and
- k = ratio of load to the allowable rivet stress, or $k = W/Sr$.

The following is a comparison of results obtained by using formula (13) with the actual required values of n as obtained by directly computing the squares of the rivet distances in each case.

$k = W/S_r$	L, in.	m	p, in.	d, in.	Required number of rivets by computation	n, by eq (13)
3.00	6.0	1	3	0	6	6.00
8.00	18.0	2	3	3	12	12.32
10.00	21.0	3	3	3	12	12.24
9.5	18.0	4	3	3	9	9.74
22.72	10.0	5	4	3	9	9.23

NOTE—The expression for moment of inertia of one rivet-line, about a central axis normal to the rivet-line, is the same for even as for odd number of rivets.

For *even* number of rivets, n, Fig. 2, the moment of inertia I_x is:

$$I_x = 2p^2\left[(\tfrac{1}{2})^2 + (\tfrac{1}{2}+1)^2 + (\tfrac{1}{2}+2)^2 + \ldots\left(\tfrac{1}{2} + \frac{n}{2} - 1\right)^2\right]$$

$$= 2p^2 [\tfrac{1}{4}$$
$$+ \tfrac{1}{4} + 1 + 1^2$$
$$+ \tfrac{1}{4} + 2 + 2^2$$
$$+ \tfrac{1}{4} + 3 + 3^2$$
$$+ \tfrac{1}{4} + \left(\frac{n}{2} - 1\right) + \left(\frac{n}{2} - 1\right)^2]$$

For $\frac{n}{2}$ terms the sum $\Sigma\frac{1}{4}$ is $\frac{n}{8}$; the sum of the arithmetical progression $1 + 2 + \ldots\left(\frac{n}{2} - 1\right)$ is $\frac{n}{8}(n - 2)$; the sum of the series of squares $1^2 + 2^2 + 3^2 \ldots \left(\frac{n}{2} - 1\right)^2$ is, calling N^2 the last term, $\frac{N}{6}(N + 1)(2N + 1)$, and substituting $\left(\frac{n}{2} - 1\right)$ for N, the sum is $\frac{n}{24}(n - 1)(n - 2)$.

Hence,

$$I_x = 2p^2\left[\frac{n}{8} + \frac{n}{8}(n - 2) + \frac{n}{24}(n - 1)(n - 2)\right]$$
$$= \frac{n(n^2 - 1)p^2}{12}$$

For an *odd* number of rivets, Fig. 3, if we still denote the number of rivets by n, we have:

$$I_x = \left[1^2 + 2^2 + 3^2 + \ldots\left(\frac{n-1}{2}\right)^2\right]$$

which, by the summation formula $\frac{N}{6}(N + 1)(2N + 1)$, becomes

$$I_x = 2p^2\left[\frac{(n - 1)(n + 1)n}{24}\right] = \frac{n(n^2 - 1)p^2}{12}$$

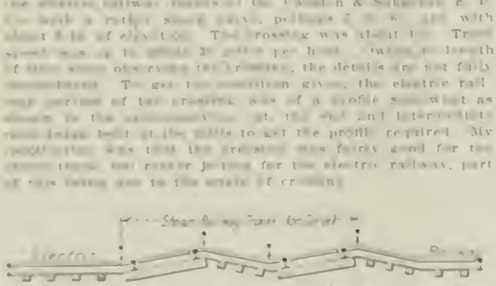
Thus the expressions for I_x are identical for odd and even number of rivets.

Track Crossings on Curves, with Superelevation

A special problem in track-crossing construction is involved in carrying an electric railway at grade across a steam-railway track when the latter is on a curve and has superelevation of the outer rails to provide for fast trains. This problem was suggested in our issue of May 21, by a correspondent who inquired as to a means by which superelevation may be introduced where one of the intersecting tracks is on a curve, so that trains may pass the crossing at high speed.

An arrangement to meet this condition seems to have been introduced in a number of cases where a steam railway (on curve) had to be crossed by an electric railway. Mr. Hare, Superintendent of Construction of the Altoona & Logan Valley Electric Ry., wrote us as follows on the subject:

About 13 or 14 years ago, the Atlantic City R.R. crossed the electric railway tracks of the Camden & Suburban E. R. Co. with a rather sharp curve, perhaps 6° or 8°, and with about 6 in. of elevation. The crossing was about [illegible]. Train speed was up to about 30 miles per hour. Owing to length of time since observing the crossing, the details are not fully remembered. To get the condition given, the electric railway portion of the crossing was of a profile somewhat as shown in the accompanying cut, the end and intermediate rails being bent at the mills to get the profile required. My recollection was that the crossing was fairly good for the steam track, but rather jerking for the electric railway, part of this being due to the angle of crossing.



Profiles of Electric Railway Tracks at Grade Crossings of Steam Railways on Curves, with Superelevation of Outer Rails. (Not Drawn to Scale.)

[illegible] crossing in question appears to have been [illegible] by [illegible] as [illegible] of the railways [illegible] have failed to [illegible] any information concerning it. But William Wharton, Jr., & Co., of Philadelphia, advise us that they have furnished crossings of this type for other locations where the steam track is on a curve, the electric rails being bent to conform to the [illegible] of the [illegible] track (with superelevation of outer rails). The construction is [illegible] to the accompanying cut.

One of these cases is the [illegible] crossing of a [illegible] track of the [illegible] with the [illegible] track of the [illegible] Division of the Boston & Maine R.R. at [illegible] Ave. St., Worcester, Mass. The electric line is on a curve of [illegible]-ft. radius and the steam line on a curve of [illegible]-ft. radius. The crossing was built of 90-lb. rails connecting with [illegible] rails of the steam track and [illegible] girder rail on the electric track. This crossing was built in 1907.

Here the profile is as shown in the upper drawing, the maximum superelevation being about 7 in. The rails are bent at four points as shown. The tread is rounded and the baseplates under the rail intersections are bent to fit the rails. The total length of crossing on the electric track is about 50 ft. The flangeways are 2 in. deep, 2 in. wide for the steam tracks and $1\frac{1}{2}$ in. wide for the electric track.

Another case is the $71\frac{1}{2}°$ crossing of the Schuylkill Valley Traction Co. (single track) over the four-track line of the Philadelphia & Reading R.R. at DeKalb St., Bridgeport, Penn. The steam railway is on a curve of about 3137-ft. radius on center line, with elevations as shown by the lower drawing. The electric railway is on tangent, with a length of about 54 ft. over the crossing. The entire crossing is built of 90-lb. rails, connecting with 6-in. 60-lb. step-head rails of the electric railway.

The rails are given a rounded bend as shown; the two outer bends give a difference in elevation of $\frac{5}{16}$ in. in a length of 19 in.; the two inner bends give $1\frac{3}{4}$ in. in the same distance. This crossing had no baseplates under the rail intersections. It may be noted that the electric line (like several others in Pennsylvania) has a gage of 5 ft. $2\frac{1}{2}$ in.

The Use of Electric Energy in the Construction of the Sun River Irrigation Project

By H. N. Savage*

The Sun River Irrigation Project, which is being constructed by the U. S. Reclamation Service, is located in Teton, Lewis and Clark, Chouteau, and Cascade Counties, Montana. Over 300,000 acres of land can be irrigated under this project, provided adequate water-supply can be developed and extension of the project to its ultimate limits is found to be justifiable from an economic standpoint.

Present development of the project (see Fig. 1) includes only the Fort Shaw unit, covering 17,000 acres of land on the south side of Sun River, mainly on the abandoned Fort Shaw military reservation, and about 90,000 acres on the north side of the river in Spring Valley and on the Greenfields bench. These lands will be irrigated by the flow of Sun River, supplemented by stored water released from Pishkun and Willow Creek reservoirs. The canal system for the Fort Shaw unit was completed in 1908 and has been in operation since that date. The first enlargement of Willow Creek reservoir to impound 19,000 acre-feet has also been completed.

The Sun River diversion dam, 180 ft. in length, located in the canyon of Sun River, will divert water to both Pishkun and Willow Creek reservoirs. The dam and the [illegible] tunnel leading from the dam to the head of the Pishkun reservoir supply canal are now under construction by government forces. Contract work is also well under way on the Pishkun reservoir supply canal, which has a length of 11 miles and a capacity for the first development of 1200 sec.-ft., and on the Sun River slope canal with a length of [illegible] miles and a capacity for the first development of 900 sec.-ft. The contracts provide for the construction of the canals complete including all structures. Location of the distribution system for the Greenfields unit is completed and plans are well advanced toward the construction stage.

*Supervising Engineer, U. S. Reclamation Service, [illegible]

The complete irrigation plan of the Sun River project provides for the storage of water (1) in a reservoir on the North Fork of Sun River, which is to have a capacity of about 350,000 acre-ft., requiring a masonry dam over 300 ft. high; (2) in the Willow Creek reservoir, capacity at final development, 86,000 acre-ft., and (3) in Pishkun reservoir, 46,000 acre-ft. There is also a possibility of storage in connection with further development in Muddy Creek reservoir near Power, and in Benton Lake reservoir 8 miles north of Great Falls. Diamond-drill borings have been completed at the site of the Sun River storage dam, but its construction has not yet been authorized as the Pishkun and Willow Creek reservoirs will furnish sufficient storage for the units of the project now built and under construction.

Adequate transportation facilities were a necessary preliminary to construction and a controlling factor in the project's feasibility. These have recently been provided in the construction of several new railway lines through the project. The Great Northern Ry. has completed a branch line from Vaughn station running westerly 10 miles up the Sun River valley to Gilman. The same company has completed and established train service upon a branch line from Power station northwesterly through the project to Chouteau and continuing northwesterly. The Chicago, Milwaukee & St. Paul Ry. has also completed a roadbed northwesterly across the project to Chouteau and beyond, and train service will soon be inaugurated.

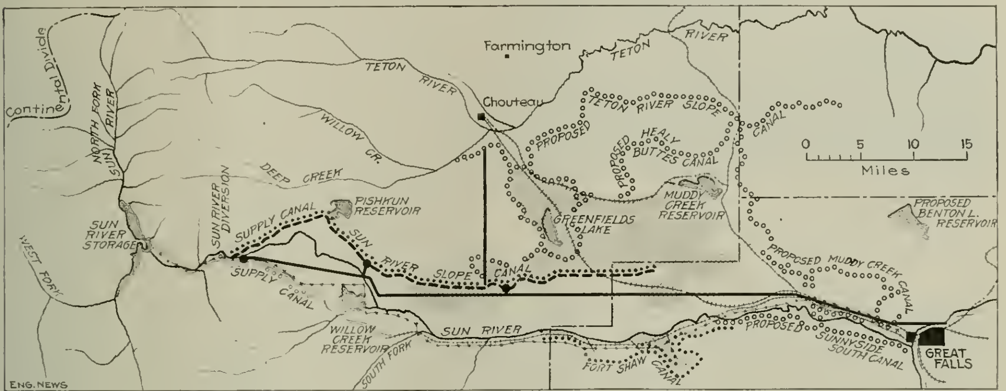


Fig. 1. General Map of the Sun River Project Works

As a further prerequisite to the largest success of the project settlers and the most economical construction of the project works, contract was entered into between the United States and the Great Falls Power Co. for electrical energy to be used primarily in constructing the irrigation system, including dams, canals and tunnels and all canal structures, and, ultimately, to insure the availability of electrical energy for the 12 small towns now scattered through the project (which were in existence before the project was put under construction) as well as for about as many more new towns projected along the new lines of railway.

This contract provides for the construction, by the power company, of over 100 miles of trunk transmission line. Starting from the company's Rainbow Falls hydro-

Fig. 2. Sun River Substation No. 2 of the Great Falls Power Co.

(Pole at right carries the 48,600-volt circuit.)

electric plant located on the Missouri River about 5 miles below the city of Great Falls, the main transmission line extends westerly through the project for a distance

FIG. 1. SWITCHES AND 15-KW. TRANSFORMER (16,500 TO 2300 VOLTS), HAYDEN BROS., SUN RIVER CONSTRUCTION WORK

of 73 miles to the Sun River diversion dam where the Willow Creek reservoir supply canal and the Pishkun reservoir supply canal divert from the river. A right-angle branch trunk-transmission line, 30 miles in length, will be extended from a point 40 miles west of Great Falls across the project to Choteau.

The Great Falls Power Co.'s transmission line is strung on wooden poles 35 ft. in length, spaced 200 ft. The energy is delivered to the substation at 18,600 volts, three-phase, 60-cycles. The transmission-line wires consist of three strands of No. 8 B. & S. hard copper. The insulators are of a suspension type. Two wires are suspended from the lower crossarm and one from the upper crossarm. A 1/4-in. stranded-steel ground wire is strung on one end of the upper crossarm and is grounded at every pole. A telephone circuit, consisting of No. 8 B. & S. copper wire, is placed on the same poles. The transmission line is transposed three times in its total length, and the telephone line is transposed at every 5th pole.

The electrical energy is delivered to the Reclamation

pacity of 900 kw. in three transformers of 300 kw. each. The transformers at the substation reduce the voltage from 18,600 to 16,500 for local distribution. Substation No. 3 also contains two transformers stepping down from 16,500 to 2500 volts for local use at the diversion dam and tunnels at the upper end of the canal system, where it is used for driving air compressors, hoisting engines, pumps, concrete mixers, ventilating fans, and for lighting and general purposes. Substation No. 3 is equipped with electrolytic lightning arresters on the 18,600-volt side; substations Nos. 1 and 2 have no lightning arresters on the high-tension side. All of the substations are of the outdoor type; but small corrugated-iron buildings are provided at each substation, in which are installed on the low-tension side of the transformers, oil switches and graphic and integrating watt meters.

The government has constructed a 16,500-volt distribution-transmission line the entire length of and adjacent to the Pishkun reservoir supply canal and Sun River slope canal, a distance of 45 miles. The line is strung on wooden poles 30 ft. in length, spaced 150 ft. The distribution-transmission line consists of No. 6 B. & S. copper wire placed on glass insulators. In order to keep this line, throughout its length, convenient to the canal work, the line as constructed is very crooked and required an unusual number of guys and double crossarms. A great number of ravines are crossed, with spans varying from 150 to 450 ft. No ground wire is used on this line. A telephone line is placed on the same poles. At points where the energy is used along the canals and tunnels, portable transformers mounted on skids or on wagons are used to step the voltage down to that required by the contractors. For the dragline-scraper work, the voltage is first stepped down to 2300 and is transmitted through a three-conductor armored cable about 1000 ft. long to the dragline, where it is again stepped down to 440 volts. At the tunnels, direct current at 250 volts is used for drills and is obtained from a 250-volt direct-current generator driven by a 440-volt induction motor.

FIG. 2. [illegible] ELECTRIC DRAGLINE EXCAVATOR; [illegible] TRANSFORMERS AND SWITCH WAGONS

Service at three substations; additional substations are to be provided when required. Substation No. 1, located at Mile 35, has a capacity of 200 kw. in two transformers of 100 kw. each; substation No. 2, located at Mile 50, has a capacity of 200 kw. in two transformers of 100 kw. each. Substation No. 3, located at the terminus of the company's transmission line, Mile 73, has a total ca-

The contract specifications for the main canals, Pishkun reservoir supply canal and Sun River slope canal, and for the structures, including tunnels, require that electrical energy shall be used by the contractors for the operation of excavating machinery and wherever else power is used in the construction work covered by the specifications. The United States is to maintain a trans-

mission line adjacent to the canal and furnish the contractor with electrical energy for the operation of the excavating machinery, all power and lighting and other purposes required under the contract.

The contract between the United States and the power company continues over a period of six years and is renewable at the option of the Government. The power company obligates itself to furnish, not to exceed a maximum of 2600 kw., continuous delivery, the United States guaranteeing to pay the company a fixed minimum sum for the total period. Electrical energy is delivered to the contractors at 16,500 volts (measured on the high-tension side of the transformers) at 1c. per kw.-hr., at the substation on the distribution line or at 1.1c., if measured at other points, and there is no service charge. The contractors supply the transformers for stepping down from 16,500 volts and for all lower voltages.

The work covered by the first contract for the construction of the Pishkun reservoir supply canal and Sun River slope canal and Tunnels Nos. 2 and 3, involving the excavation of about 2,400,000 cu.yd. of material and the construction of about 3260 lin.ft. of concrete-lined tunnel, was secured by the MacArthur Bros. Co., of New York and Chicago.

The construction of structures for these same two canals involves about 82,000 cu.yd. of excavation, 14,000 cu.yd. of concrete, the placing of about 664,000 lb. of reinforcing steel, the erection of about 10,000 lb. of structural steel, the placing in wooden structures of about 66,000 ft. b.m. of lumber and the laying of about 24,000 lin.ft. of drain pipe. This contract was awarded to the Hayden Bros. Co., of Portland, Ore. The contractors are now actively engaged in carrying out the construction of the work, utilizing electrical energy wherever power is required.

Excavating Machines—Two dragline scrapers were made for the contractors and have been in successful operation for several weeks. The first machine (Class 24 Bucyrus) has a 24-ft.-diameter swing circle, 100-ft. boom and a 3½-yd. extra heavy bucket (Page). The main motor is of 225 hp., and the swinging motor 115 hp. These motors are of a slip-ring induction type, intended for severe intermittent variable-speed reversing service. They are operated by automatic solenoid control, so designed as to make it impossible for the operator to injure the motors by improper handling of his levers, and to make the handling of the electric machines the same as the steam. The excavator is mounted on skids and wooden rollers. The current, which is brought to the machine in a three-wire armored cable at 2200 volts, is transformed in the base of the machine to 440 volts; the motors operate on the three-phase 60-cycle 440-volt current thus supplied.

The second machine (Class 20 Bucyrus) has a turntable of 20-ft. diameter, a boom 85 ft. long and a 2½-yd. extra heavy bucket (Bucyrus). The main motor is of 135 hp. and the swinging motor of 75 hp. The motors and control are of the same design as used on the other machine. This machine is also mounted on skids and rollers, and the current is similarly supplied.

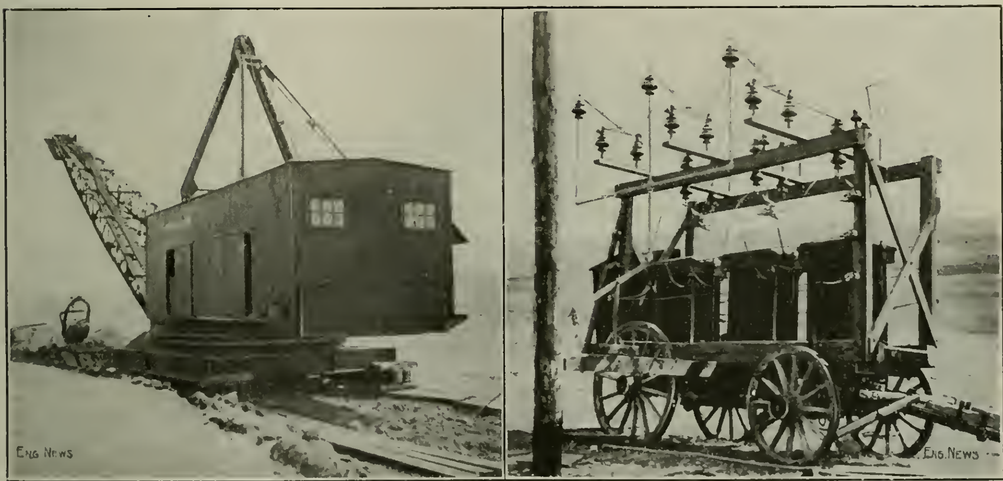

Fig. 6. Class 20 Electric Dragline Excavator and the Transformer and Switch Wagon

The cost of the energy used by the dragline scrapers has averaged about $0.85 per cu.yd. of material moved.

The Reclamation Service is constructing the diversion dam (which is concrete masonry and is to have a total height of 140 ft.) and Tunnel No. 1, with Government forces, using electrical energy wherever power is required.

A Year's Progress on the Lincoln Highway, from New York to San Francisco, gives reason to believe that the undertaking will be carried out successfully without federal aid. About 2500 miles of the total 3400 miles have been marked by the Lincoln Highway Association, and the association has supplied local communities with $40,000 worth of cement to be used in road improvement. In Ohio over three-fourths of the whole has been paved. In Indiana local communities have issued bonds to the amount of $350,000 for improvements not previously contemplated. Sections in Illinois are in the new state-aid road system. In the West much improvement work has been done, particularly in Nebraska, Colorado and Wyoming. The whole highway is in such shape that the transcontinental trip by motor car may easily be made in less than a month.

A Tunneling Machine for Clay or Stiff Sand Formations

A tunneling machine of the boring type, for use in clay or stiff sand and gravel formations, has been in use for some time on a section of the Mount Elliott Ave. sewer in Detroit, Mich., and is now about to be put in operation on the new water tunnel for the City of Cleveland under Lake Erie. The machine was designed by [illegible] of Port Huron, Michigan, a practical tunnel worker who is foreman for the Mount Elliott Ave. sewer work, and is controlled by Carpenter & Anderson, general contractors and engineers, [illegible] Widdicomb Bldg., Grand Rapids, Mich., and 508 [illegible] Trust Bldg., Detroit. This firm has the contract for Section 2 of the Mount Elliott Ave. sewer, most of which is being excavated with the tunneling machine. The City of Cleveland has leased two of the machines for work on its new waterworks intake, and is to pay a small [illegible] royalty to Car-

[illegible] cutting tool makes a spiral cut in the tunnel heading. The machine carriage is further provided with a traveling belt mounted beneath the shaft, leading back to another traveling belt which can be elevated so as to dump into a car.

The operation of the machine is as follows. A full section is first made, by ordinary mining methods, a sufficient distance to allow the entrance of the tunneling machine, which is either mounted on a track or upon some bearings sufficiently elevated to center the main shaft. The [illegible] knife is then centered in the tunnel heading and the machine started. The shaft is so geared that an advance for the full length of the knife, that is, about 15 in., is automatically made, the knife making a conical cut of that depth. The boring knife is then thrown out of gear and the [illegible] thrown into gear, and the cutting tool set to work on the [illegible] in the cut made by the knife. The cutting tool is 6 in. deep and 6 in. wide in the diameter of the tun-

[illegible]

[illegible]

[illegible]

In the Detroit work, the weight of the machine, [illegible]

that unless the machine is held it will pull forward toward the tunnel heading.

The section of the Mount Elliott Ave. sewer bored by the machine is about 5000 ft. long. The cut made by the machine is an 11-ft. 2-in. circle and the finished section inside the brick lining has a 9-ft. clear diameter. This tunnel was dug from three shafts; in the first one the heading for a short distance in one direction was driven by ordinary mining methods and in the other by the machine. The formation here was of a stiff blue clay, which stood up very easily and cut very readily. The following figures show the comparative costs of driving the tunnel by the machine and by ordinary mining methods, the conditions, except for the method of driving, being precisely similar.

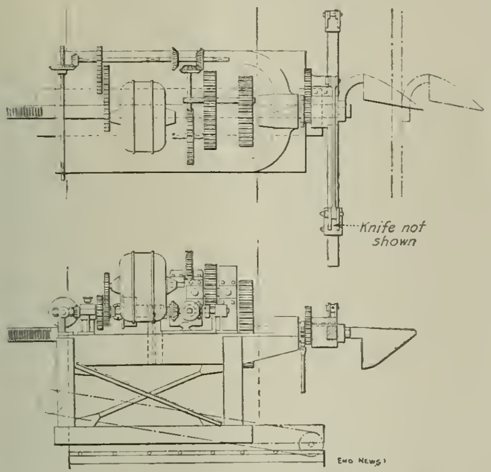

Fig. 2. General Details of the Bonnett Tunneling Machine

In the hand method, the labor charge was as follows: 6 miners at \$5.50 ea., 3 muckers at \$2.75 ea., 1 to 4 car pushers at \$2.75 ea. This force averaged 8 ft. per day of 8 hr.

With the machine there were two operators, one on the machine at \$4 per day and one on the knife at \$3 per day; two muckers in front at \$2.75 per day; two handy men at \$2.75 per day. This force averaged 12 ft. per day of 8 hr.

Behind both of these forces bricklayers were laying the brick lining. These men had to be paid \$10 per shift, no matter how long the shift was. With the ordinary mining method, the cut made during the shift previous to the bricklaying shift was often not long enough to keep the bricklayers busy, whereas with the machine the cut was always sufficient to keep them throughout their regular 8-hr. period. In addition, the miners made a much greater overrun than did the machine, which cut true to line and did not require any extra backing. With the hand method sometimes the extra brick backing was as much as 500 bricks per shift.

In some places in the tunnel some rather unsatisfactory sand was met with, and in these places the roof of the tunnel had to be timbered. It is stated, however, by the engineers on the work that the machine did very well in this formation. In a number of places quite large boulders were encountered, but these were picked out by the muckers and gotten out of the way without injuring the machine or impeding its progress.

In the Cleveland tunnel work the two machines are to be used in a shield, with a concrete-block lining machine directly behind them. For a while, at least, they will have to be under air, but it is hoped that the ground will be tight enough to allow open-air driving to proceed.

Figs. 3-4 show the comparative appearance of the machine and hand work in the Mt. Elliott Ave. sewer.

Economics of Sewage Filters*

By [illegible]†

[illegible] OF FILTERS.—The output of a filter of any type [illegible] at any suitable [illegible] unit, is largely a question of local conditions. It depends upon the nature of the sewage, the nature and fineness or coarseness of the filtering material, the method of application of the sewage to the filtering material, temperature, atmospheric conditions, and many other factors.

Not considering special conditions and just taking fair figures, we can safely state the following:

Intermittent sand filters, 5 ft. bed of sand, loading [illegible] population per acre; contact filters, 4-ft. depth of stone, loading [illegible] population per acre; sprinkling filters, 7 ft. depth of stone, loading [illegible] population per acre.

The ratio, then, for these three types of filters are in the ratio 1, [illegible] and 10 [illegible].

COST OF SEWAGE FILTERS.—Costs of construction are so much affected by local conditions, such as the amount of excavation necessary, the cost of various classes of materials, the distance from which various classes of materials must be obtained, details of local construction conditions, such as competition, class of work required, and classes, that comparative costs for different localities are only to be used with great discretion, and individual cost and even averages are only a guide to comparative costs in various places. Having this limitation in mind, we will examine in a rough way the cost of various types of sewage filters on the per capita basis.

The average cost of [illegible] Massachusetts intermittent sand filters is $[illegible] per acre, as reported in the Massachusetts State Board of Health Report of 1903. This gives a cost per person connected to the filters of $3.50.

The 1906 Baltimore Sewerage Commission estimates that the cost per acre of filters at $[illegible], these filters being suitable for a connected population of 1200 per acre. This corresponds to a per capita cost of $[illegible].

The cost of contact filters, varying, of course, with the degree of the fineness of the [illegible], may be taken, for filters equipped with suitable convenient appurtenances, at $[illegible] per acre for a 4-ft. deep bed. This corresponds with a loading of [illegible] population per acre to a per capita cost of $[illegible].

For sprinkling filters 7 ft. deep the cost will be about $[illegible] per acre. On the basis of a loading of 19,000 population per acre, the cost per capita will be $2.[illegible].

When considering the relatively low cost of the Massachusetts sand filters compared with the estimate made from the Baltimore sand filters, it is to be borne in mind that the conditions in Massachusetts for the construction of sand filters were generally favorable and the cost represented average conditions through the country. In most places the costs would approximate more nearly those estimated for Baltimore.

Taken on a broad basis, sprinkling filters are by far more economical to construct on the basis of first cost. Intermittent sand filters and contact filters do not stand far apart in this particular.

RELATIVE COST OF DIFFERENT DEPTHS.—There is but very small known about the relative advantages of filters of shallow or deep construction. The choice of depth is usually made for entirely different reasons from those of considering the most economical construction to obtain the desired amount of purification. Very few tests of a comparative kind have been made to give convincing information, and the interpretation of the tests has not been uniform. In some places the conclusion has been made to make filters, say 10 ft., at other places 6 ft., and accordingly is worth while to determine what if any difference there be in the cost of such construction at different depths, and which would appear to be the better. It is to be assumed in such comparisons that sufficient head would be available in any case for the greatest depth to be considered and that pumping would not be necessitated by building filters of the greater depth.

For intermittent sand filters questions of depth do not arise. The filters are generally made as shallow as is consistent with getting proper results and sand beds are not usually made more than 4 or 5 ft. deep as a maximum. Shallower beds, even, will give about the same output as the deeper beds, and beds are made deep only so that sand may be removed for cleaning without removing the sand for a considerable period.

With contact filters it is recognized that from the nature of the action of the contact filters, where the amount of air that is drawn in between fillings of sewage is practically equal to the volume of the sewage, and where surface clogging cannot be a serious factor and may even be no factor at all, each unit of volume of the stone forming the filter, say each cubic yard, will give the same output of sewage purification, no matter what may be the depth of the filter.

From this it follows that it is economical to build a sewage filter on the contact principle as deep as local conditions of construction will permit, and the limitation of depth which it is economical to use is therefore made by the factors of earth excavation or fill and the possible head available without pumping.

When it comes to sprinkling filters, the problem becomes a little more complicated. The English experience, as recited in the Report to the Royal Commission, seems to indicate that the output per unit of volume of sprinkling filters is the same, no matter what the depth. Our experience in work in this country does not wholly corroborate this information. Our best knowledge seems to indicate that the output per unit of volume of sprinkling filters is somewhat less for deep filters than for shallow filters. For such conditions, with a relatively decreasing efficiency of the stone of the filter beds for greater depths and at the same time a relatively decreasing cost per unit volume of the stone for deep beds, there must come some point where the greatest output per unit of cost will be obtained.

The Report of the Baltimore Sewerage Commission in 1911, gives some information obtained from tests made in Baltimore as to the relative efficiency of various depths of [illegible] stone of [illegible] in [illegible] filters, which is the one most commonly used. Figures obtained from that source show the following:

	[illegible] ft.	[illegible] ft.	10 ft.
Relative [illegible]	[illegible]	[illegible]	[illegible]
Per cent. reduction of [illegible] consumed	[illegible]	[illegible]	[illegible]

Giving equal weight to the relative stability and per cent. reduction of oxygen consumed, we get the following:

	[illegible] ft.	[illegible] ft.	10 ft.
Relative stability	1	1.[illegible]	1.[illegible]
Per cent. reduction of oxygen consumed	1	1.[illegible]	1.[illegible]
Average of the two	1	1.[illegible]	1.[illegible]
Relative depths	1	1.[illegible]	2.[illegible]
Relative value of [illegible] per [illegible]	1	.[illegible]	.[illegible]

*From a paper [illegible] before the [illegible] Society of [illegible] [illegible], [illegible].

†Consulting Engineer, [illegible] Broadway, New York City.

Assuming this depth varies at a uniform rate from one end of the curve to the other, we get the following for the relative value of stone per cubic yard:

Depth of bed	6 ft.	7 ft.	8 ft.	9 ft.	10 ft.	12 ft.
Relative value of stone per cu.yd.	1.0	0.97	0.94	0.92	0.82	0.63

To get comparative figures, then, between the 6-, 8- and 10-ft. beds, the cost figures for the 8-ft. beds must be divided by 0.94, and the cost for the 10-ft. beds by 0.82, putting them all on the basis of the 6-ft. beds.

For comparative cost a number of factors, such as excavation, etc., are naturally omitted, as they are not affected in all places the same way by the depth of the filter. Comparing, then, only those particular costs which are affected per unit of output by the depth of the filter, we get the following costs per effective cubic yard for depths of 6, 7 and 8 ft.:

	Depths, ft. 6	7	8
Floor	$0.40	$0.35	$0.32
Tile	.49	.44	.40
Walls	.17	.17	.18
Galleries and Collectors	.25	.22	.20
Distribution	.50	.50	.50
Stone	1.50	1.55	1.60
Total	$3.31	$3.23	$3.20

Outside factors will depend on quantity only and not on depth.

It appears, then, that there is some slight saving of cost, which, on the figures given in the table, amount to about 3%, in favor of the 8-ft. deep bed, as compared with the 6-ft. deep bed. On the other hand, it is to be recognized that a deep bed will give a good deal more trouble with pooling and freezing than a shallow bed, and the advantages in favor of a shallow bed due to this lesser amount of pooling will be considerably more than this 3% difference in cost. Taking everything into account, the writer believes that a sprinkling filter of bed of not less than 6 ft. and not more than 7 ft. will, in the greater number of cases, prove the most economical to use.

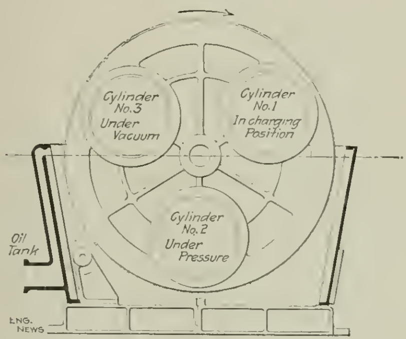
A New Type of Creosoting Plant

A creosoting plant of novel type now being tried in Scotland has as its special features an entirely new design of the treating plant, a very short period of impregnation, and a very high pressure for this impregnation. The retort consists of three horizontal cylinders 33 in. diameter and 28½ ft. long, mounted between two end plates or disks which have openings to receive the cylinders and are carried by a central longitudinal shaft. The entire machine is immersed in an oil tank which is kept filled to the level of the shaft. The general arrangement is shown in the accompanying cut. The end plates are driven intermittently by gearing in such a way that every four minutes the retort revolves through an angle of 120°. The movement occupies 18 sec., the retort being then at rest for 3 min. 12 sec.

In the first position, with two of the cylinders above the level of the tank, the cylinder at the right is in line with the feed trough (above the end of the tank) and a charge of 24 ties is pushed in by a ram. The frame then revolves (clockwise) 120°, immersing the cylinder in the tank. After 60 sec. (to allow the fluid to completely fill the cylinder), sealing pistons move out and close the ends of the cylinder in 12 sec. A pressure of 400 to 500 lb. in the cylinder is then raised by pumps in 12 sec. and maintained for 2 min. 6 sec., followed by a release in 12 sec., completing the 4-min. period.

The frame then revolves 120° bringing the cylinder out of the tank (and immersing the second cylinder). Other sealing pistons again close the ends while a vacuum is created to withdraw a proportion of the creosote. The frame then revolves through 120°, completing its revolution, when the charging ram pushes in a new charge of ties, thus pushing out the treated ties at the other end. The operations are the same with each of the three cylinders, so that at each 4-min. interval a charge of 24 treated ties is ejected.

The partial recovery of oil from the wood is one of the



Sectional Elevation of Revolving Triple Retort for Creosoting Ties

features of the system (which is termed the "save-oil" system), and a series of tests of this process and the full-cell process showed results as follows:

	Save-oil process	Full-cell process
Average increase in weight per tie.	21.22%	30.05%
Average creosote per cu.ft.	7.04 lb.	9.97 lb.
Average creosote per tie	2.18 gal.	3.09 gal.

The plant can be adapted, however, for the full-cell creosoting process or for the zinc-chloride process, the vacuum treatment being then omitted. The operation is continuous and rapid, and gives an output of 360 ties per hour. The plant is compact and occupies comparatively little space, but has considerably more machinery than a plant of the ordinary type. It works also on the principle of high pressure maintained for a short period, the actual pressure period being but a few minutes instead of several hours. However, the amount of oil forced into the wood is said to be greater than by the ordinary process. Ties, poles, bridge timbers and paving blocks can be treated in the same way.

The new process and plant are owned by the Saveoil Creosoting Co., Dickson, St., Glasgow, Scotland. Experiments were made first at the Royal Technical College, Glasgow, and as a result of these a complete plant has been erected at the creosoting works of the Glasgow & Southwestern Ry. Our information is taken from an article in *The Engineer*, of London.

The Pavements of Guayaquil, Ecuador, consist of large blocks of stone averaging 12x12 in. on top. They are laid directly on the soil. About 15 miles of a total of 45 miles of streets are so paved.

The Volumetric Measurement of Liquids on a Large Scale

By Geo. Jacob Davis, Jr.*

It is the purpose of this article to point out some of the causes of error in the volumetric measurement of liquids on large scale and the magnitudes of the errors, together with a method of gaging measuring basins to avoid errors, in so far as possible.

Gaging the Measuring Basin.—In many cases it is desirable to measure liquids in calibrated tanks or basins. A tank for this purpose is usually provided with a glass gage or other device for showing the depth of contained liquid, and on the gage scale is marked the weight or volume of liquid contained in the tank at various heights. In gaging the tank or basin a definite amount of the liquid is weighed into the tank and a mark is made on the gage scale, and the operation is repeated until the tank is full.

Before beginning the calibration the weighing scales should be tested under various loads by standardized weights. Scales are subject to a number of errors which may be summarized as: (1) erroneous graduation of the scale arm; (2) poise of wrong weight; (3) weights inaccurate; (4) shifting of knife edges in the link bearings. On account of the last mentioned errors the scales should be placed in their final position before calibrating and should thereafter be protected from jars or vibrations which might shift the positions of the knife edges. A variation of over 0.2% has been found in scales before and after moving them from one part of a room to another. (The accompanying data sheet shows a convenient form for tabulation of data.)

If the tank has practically vertical plane walls, the average cross-sectional area may be determined, from which, with the initial and final gage heights, the contents may be computed. Usually, however, there are projecting gates, etc., and irregularities in the side walls which make this method impracticable. In six gagings of a [illegible] tank by a number of senior students, the computed average horizontal cross-section ranged from 164.8 sq.ft. to 168.2 sq.ft., a variation of over 2%. With the following method, devised by the writer, the maximum variation from the mean capacity of the tank, as determined by half a dozen calibrations by different parties of students, is not more than 1/10 of 1%.

The volume of each tankful of water weighed into the basin was calculated by dividing the observed weight by the density of pure water at the observed temperature, careful observations having shown that the density of the lake water was the same as that of pure water, out to the fifth decimal place. The volume of water in the basin at various depths could not be conveniently plotted, against gage heights, to a sufficiently large scale to show the discrepancies in the various calibrations, so the following method was adopted. Since the smallest horizontal area of the basin was a little above 160 sq.ft., the volume of contained water above the zero of the tank gage is given by

$$V = 160\,G + X$$

in which G is the tank-gage reading and X may be called the excess. It was not possible to read lower than about 0.3 ft. on the gage scale, owing to its being placed too low, so the absolute quantity of water in the basin above the zero of the gage could not be determined by the above formula, but the excess volume, x, between any two gage heights, g_1 and g_2 is given by the formula

$$v = 160\,(g_2 - g_1) + x$$

in which v is the actual volume of the tank between gage heights g_1 and g_2. In gaging the basin the elementary excesses, for each tankful of about 1800 lb. of water were calculated, and these were summed as shown (accompanying data sheet) in the column headed cumulative excess, which shows the total excess between any observed gage height and the initial gage height of that particular gaging.

In order to compare the results of different gagings of the basin, it was necessary to determine what the excess would have been had all the initial gage readings been the same. This was done by dividing the data of each gaging into two groups of observations and determining the average gage reading and the average value

[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

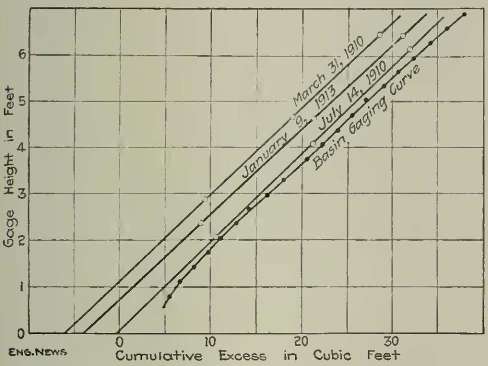
of the elementary excesses for each group and also for the entire gaging. These values when plotted on cross-section paper will lie on a straight line if the calculation is correctly done. The average lines for three gagings have been plotted in the accompanying figure. The intercepts of these lines on the X axis were added to the values of the cumulative excess and the resulting values were plotted as abscissas against gage heights as ordinates. The corrected cumulative excess for the January, 1913, gaging only has been plotted to avoid confusion. An irregular line has been drawn through the points, which shows the variation in the horizontal cross-section of the tank due to projections and other irregularities in the walls. The results of any number of gagings may thus be put on a comparative basis. If the plotted values deviate much from a straight line this method will



Comparison of Basin Gagings at University of Alabama

not give satisfactory results unless the gagings cover practically the same range of elevations in the basin.

To compute the quantity of water V in the basin between gage heights G_1 and G_2 the following formula is used:

$$V = 160\ (G_2 - G_1) + (X_2 - X_1)$$

In this formula X_1 and X_2 are the corrected cumulative excess for gage heights G_1 and G_2, respectively, and are taken from a curve similar to that shown but plotted to a large scale. The constant 160 applies to the particular tank used in the above experiments only.

Temperature Errors—In case the liquid to be measured is at a different temperature from that used in gaging the tank an error will be introduced on account of the variation of the specific volume of the liquid at different temperatures. For example, suppose a measuring tank is graduated at 60° F. to show the weight of water, in 100-lb. units, contained in it when filled to certain elevations, and water at 100° F. is afterwards measured in it. The volume of 100 lb. of water at 60° is 1.6031 cu.ft. and the weight of 1.6031 cu.ft. of water at 100° is 99.383 lb. Therefore an error of 0.617% would be introduced into the measurements, assuming the volume of the tank to remain constant. If the tank is made of thin steel which would have practically the same temperature as the contained water, the tank, as well as the water would expand with the increase in temperature, but not at the same rate. Assuming a coefficient of linear expansion of steel of 0.0000065, the new volume at 100° of the portion of the tank formerly occupied by 100 lb. of 60° water would be 1.60425 cu.ft., which would contain 99.460 lb. of 100° water, giving an error of 0.54%. On account of the shape of the expansion curve of water the error will rapidly increase with the temperature. For example, if the tank is gaged at 75° and water at 180° is measured in it, an error of 2¾% will be introduced into the readings.

In the case of a large concrete measuring basin where the gage was located some distance away in an engine room the temperature of the gage and its contained water was at times quite different from that in the basin. In the winter when the water in the tank was at a temperature of 4° C., the gage temperature was found to be 20° C. When the gage indicated a depth of 8.000 ft. at 20°, it was balanced by a depth of 7.986 ft. of heavier water at 4°. The gage readings were, therefore, in error 0.175%. This error is small as compared with those permissible in commercial work, but such constant errors should not be allowed in experimental work. The data shown in the tabulation sheet were taken in the summer when the temperature of the water in the gage and in the basin were the same and hence in this case there was no correction to apply to the gage heights. In the diagram, however, it may be seen that the average line for the January gaging has a flatter slope than those taken in the summer, which is fully accounted for by the fact that the correction for gage temperature was not applied.

Absorption—There is a possibility of the masonry wall of measuring basins absorbing an appreciable amount of water if they are dry at the time of filling. The effect of such absorption was investigated by Fteley and Stearns* in their experiments on weirs. It was found that the dry brick of the walls absorbed 12% of their volume, while brick taken out of the water and left standing on end in a damp place when again immersed absorbed 1½%. If the cross-section of the measuring basin is small in comparison with the thickness of the walls the percentage of error due to neglecting the absorption may be relatively large.

Leakage—In the operation of sluice gates various amounts of leakage are likely to occur, due to chips preventing the gates shutting tightly. In the attempt to shut the gate sufficient force is sometimes applied to buckle he gates slightly, thereby causing an increase in the leakage. After shutting the gate tightly the hand wheel should be reversed so as to relieve the gate and stem of all strain. The gates should be so placed that it will be easy to inspect them during each experiment, to detect leakage.

Large leaks through the walls may be stopped by calking, or pointing up the cracks, and small leaks can be reduced by putting bran and other sediment in the water, or by the use of a waterproof paint. The rate of leakage should be determined by filling the tank to various heights and noting the drop in the water surface in, say, ten hours, making due allowance for evaporation.

Yielding of Walls—Rectangular basins of wood or metal are likely to become distorted due to the weight of the liquid. The practice of computing the capacity of such basins from contours of the side walls when empty would therefore be inaccurate. The method outlined above would give correct results.

Field and Office

Novel Stop for Gantry Cranes

The recent wrecking by a high wind of a large gantry crane used for handling coal in storage, directs attention to the extent to which such structures are menaced by violent storms. Included in the coal-handling equipment at the Astoria, L. I., plant of the Consolidated Gas Co., of New York, is the largest such gantry crane ever built. It is 600 ft. long, with a span of 250 ft. c. to c. of tracks. It weighs 320 tons and runs on a track about 1000 ft. long. A wind of sufficiently high and sustained velocity

FIG. 1. ARRANGEMENT OF STOP LOGS ALONG RAILS

to move a 320-ton gantry crane is not a frequent occurrence, but only one such gale is required to send several hundred thousand dollars to the scrap heap.

At the time this structure was built the engineers of the gas company recognized the seriousness of this matter and undertook to provide safety devices for preventing the gantry being driven off the tracks by the wind. The last 50 ft. of the rails at each end of the track were inclined upward 1 ft., and 8x8-in. wood stringers were bolted to each side of the rails of the last 25 ft., as shown in the sketch, Fig. 1. The top of the rail head is 2 in. below the upper face of the stringers, or stop logs as they are called.

FIG. 2. THE 600-FT., 320-TON, COAL-HANDLING GANTRY CRANE AT ASTORIA, L. I.

([illegible] See Fig. 1.)

A consideration leads us to the value of this device because as an extreme condition that the gantry was caught in the [illegible] gust of a gale and given a velocity of 15 ft. per sec.

Should a runaway occur, when the forward trucks of the gantry ran up on the inclined rails gravity would tend to bring the crane to a stop. The main resistance, however, is introduced when the double-flanged wheels mount the stop logs. The flanges would, of course, crush into the timbers, developing a high tractive resistance.

The Astoria gantry crane was built by the Brown Hoisting Machinery Co., Cleveland, Ohio, in 1908. The tracks, including the safety device, were designed and constructed by the Engineering Department of the Consolidated Gas Co.

Lining a Railway Tunnel with Concrete by Compressed Air

A recent application of the method of delivering concrete in place by means of compressed air is the lining of the Alkali Summit tunnel on the new line of the Chicago, Burlington & Quincy R.R., between Thermopolis and Orrin Junction, Wyo. The tunnel is 800 ft. long, in sandstone which required timbering throughout. It was completed in 1913, and is now being lined with concrete. The tunnel has vertical sides and arch roof.

The timbering is removed in advance, as it does not leave sufficient room for the new lining. It is pulled down by fastening to the feet of the posts a cable which is led through a snatch-block at the middle of the track and attached to a dinky locomotive. Any loose rock in the roof is removed. To protect the men erecting the forms, roofing planks are laid from the completed concrete to the next set of timbering. These planks would catch small pieces of rock, while larger rocks would be impeded and would give sufficient warning to enable the men to get out of the way. The length of timbering removed at one time varies from 5 to 20 ft., according to the apparent safety of the rock roof.

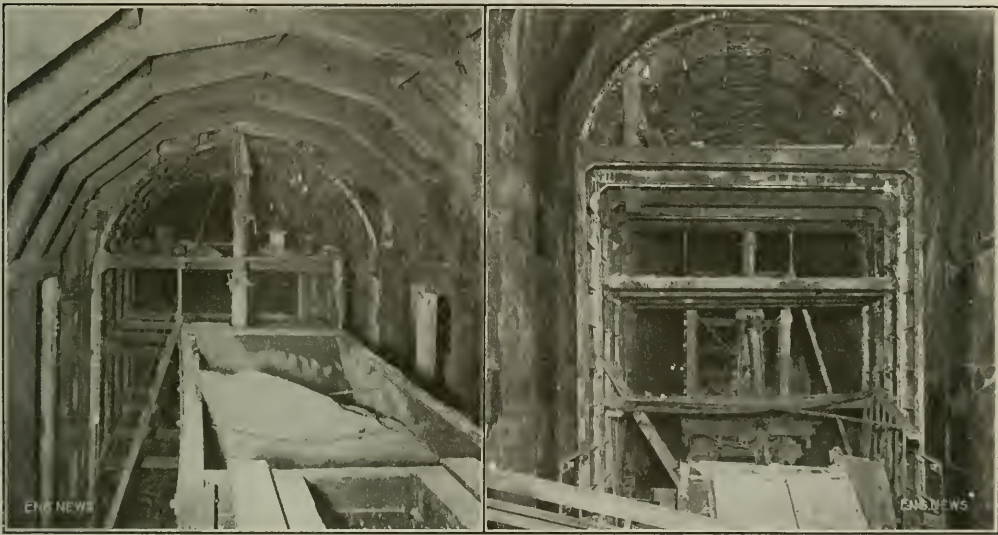
The forms are of steel, consisting of channel ribs (shaped to the tunnel section) placed 4 ft. apart and carrying a lagging of steel plates 4 ft. long and 8 in. high. This lagging is built up to the top of the arch, as forcing the concrete into place by compressed air permits the forms to be built complete before concreting begins. From one to five lengths of the forms are set up at a time, depending upon the character of the rock.

The mixing and placing outfit consists of a pneumatic concrete mixer and conveyor mounted upon a 40-ft. flat car, equipped with bins holding 26 cu.yd. of material. The cement is stored in bags under one of the bins, and discharged toward the center of the car through chutes into a measuring hopper, which is tilted automatically by a 6-in. air cylinder to discharge into the mixer. The 8-in. delivery pipe leads from the mixer under the car and vertically up at the end to the crown of the arch, where a 90° elbow enters through the bulkhead of the form and forms the delivery nozzle. The top section of the pipe, with the elbow or nozzle, is slung from the roof by tackle, and has a screw-joint connection with the vertical pipe at the end of the car. It can be swiveled horizontally so as to direct the stream of concrete to all parts of the form. Air is supplied from a compressor at the mouth of the tunnel by a 4-in. main, with hose connections to the receiver on the car.*

This portable concreting plant requires for proper working a compressor with a capacity of about 300 cu.ft. free air per minute, at 80 to 100 lb. pressure. In beginning the work, however, the only compressor available was one in poor condition and furnishing only about 80 cu.ft. per minute. It was driven by a gasoline engine.

The sand and gravel, dredged near Casper, is hauled in gondola cars and delivered along the track near the tunnel. Cement is stored in a small shed. The bins on the car are loaded by a portable derrick with a wooden skip which is filled by shoveling, as a clam-shell bucket was not available. The car was taken into the tunnel by means of the dinky engine and spotted at a point next to the forms, and its delivery pipe connected to the upper section was suspended in place. The air connection was then made and concreting immediately commenced.

For the first 20 ft. of the lining the work was as follows: Tearing down the timbers, 128 man-hours; erecting forms, 229½ man-hours; loading gravel and cement onto the car, 140 man-hours; mixing and placing concrete in the forms, 204 man-hours. The total yardage placed was 132 cu.yd. The number of man-hours required per yard of concrete was 0.97 for tearing down and clearing timbers, 1.74 for erecting forms, 1.5 for mixing and placing concrete and 1.06 for loading gravel and cement. The delays were 3½ hours on account of blowing off an 8-in. nipple, and 2 hours on account of a derailment of the derrick car.



PLACING CONCRETE LINING BY COMPRESSED AIR IN THE ALKALI SUMMIT TUNNEL; CHICAGO, BURLINGTON & QUINCY R.R.

(The view at the left shows the head of the concreting car, with its material bins and vertical concreting pipe. The top section of this pipe, with elbow entering the end bulkhead of the form, is suspended from the roof by tackle, and has a swivel joint with the pipe on the car. The timbering is removed as the concrete lining advances. The view at the right shows the concrete lining and the steel forms, the latter consisting of ribs and panel plates.)

The substitution of a clam-shell bucket is expected to cut the cost of loading the car to about 0.3 man-hour (or, say 10c. labor cost) per cu.yd. The substitution of a 300-ft. compressor will make it possible to mix and place one batch per minute. The number of batches made with one loading of the car varies between 112 and 118. The time required for placing this amount of concrete, including time of transporting and for connecting and disconnecting the delivery pipe, is about 210 to 240 min.

This portable outfit was designed by the Concrete Mixing & Placing Co., of Chicago, Ill., which also furnished the pneumatic mixer and conveyor apparatus.

*This concreting car was described and illustrated in "Engineering News," March 26, 1914. At that time, however, the delivery pipe was inclined, while the vertical pipe has been found much more satisfactory.

Fish in Chicago Water Mains—During the past year 153 fish traps were installed where complaints were continually received of meters filling up with fish. These traps were so constructed that consumers could clean them without calling on the Water Department

Rod for both Stadia and Direct Leveling

BY [illegible]*

Fig. 1 shows a pattern for a combined stadia and level rod which has proved by long experience to be of great practical value. It is substantially the design of Harold Van De Zee[illegible], consulting engineer of Philadelphia, Penn. [illegible]

[illegible]

[illegible] 0.02 allows a more [illegible] marking than into 0.01, while there is no difficulty in estimating to 0.005; that after an hour's practice, one can almost instantly and automatically take an accurate reading; that it can be read at considerably greater distances than the usual [illegible] patterns; and that it may be adapted to a rod of permissible weight.

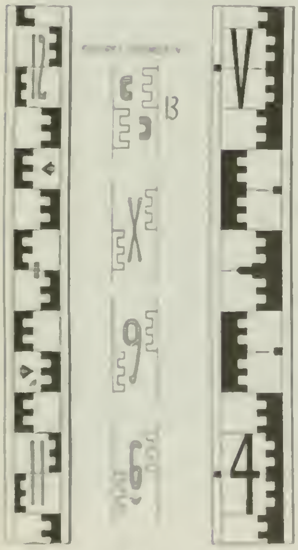


FIG. 1 FIG. 2 FIG. 3

[illegible] LEVEL ROD

[illegible]

[illegible]

[illegible]

[illegible]

*[illegible]

[illegible] alternate tenths, so that the paint is not rubbed [illegible].

Fig. 3 illustrates another pattern, also a design of Mr. Van De Zee's, which allows a longer range, though not so easily adaptable to a rod of as light weight as is the first.

※

Steel Tank for Coal Storage

The proprietor of a [illegible] coal yard at North East, Penn., stores his stock, except the large lump varieties of coal, in a circular steel bin, fashioned somewhat after the manner of a circular grain bin. The dimensions of the bin are, height and diameter, each about 40 ft. It rests on a brick foundation about [illegible] ft. high.

The coal which is to be unloaded into the bin is allowed to run from hopper-bottom cars into a pit under the [illegible]. A [illegible] conveyor, inclosed in a [illegible]

STEEL TANK FOR COAL STORAGE, NORTH EAST, PENN.

[illegible]

[illegible]

suddenly remember that they forgot to order coal. No insurance is carried on the bin shown in the accompanying view. The builder is the VonWald Engineering Co., of Buffalo, N. Y.

A High-Speed Valveless Displacement Pump

An unique design of valveless pump, giving large capacities for small sizes and weights is shown in the accompanying figures. The type is adaptable for wide ranges of service and a standardized line is available. It is reported that satisfactory service has been secured (with single-stage units) for hot and cold water, gasoline and volatiles, heavy fuel oils, molasses, soaps, sludges, tar and asphalt; vacuum pumps and compressors have been built in one-, two- and three-stage units. The principle is familiar but has not before been commercialized for miscellaneous small services or in such multistage single-impeller units.

The relative sizes and capacities may thus be shown: For general water-supply, boiler feed, etc., a small unit, 17x12¾x12¾ in. with 1½-in. suction and discharge runs from 50 to 800 r.p.m. and discharges 0.035 gal. per revolution; the maximum designed pressure is 200 lb. per sq. in. and the maximum capacity 25 gal. per min. The largest unit for this service is 26x20x22 in., runs at from 50 to 700 r.p.m., and has a maximum capacity of 300 gal. per min.

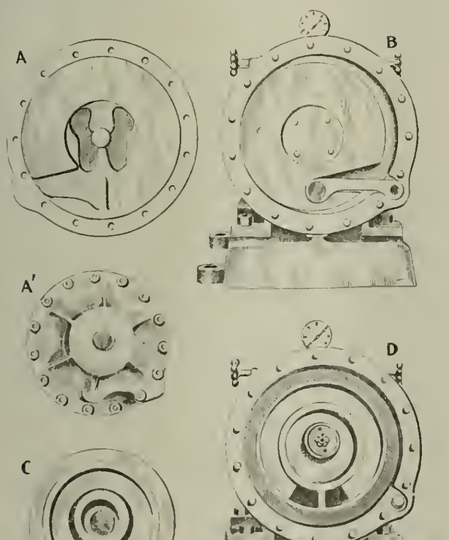

FIG. 1. THE MAY-NELSON PUMP TAKEN APART
(A, A', cover removed; B, impeller and back link in place; C, D, impeller removed.)

The same pump may be used for vacuum service working at 24 in. wet or dry, and giving an air displacement of 0.0017 cu.ft. per revolution or 10 cu.ft. per min. at maximum capacity. A special design (three-stage) of high-vacuum pump supplements the general line noted, holding a vacuum of 0.05 mm. pressure; the same pump may be used to furnish both suction and blast if desired. Another special pump, 4x4¾ in. and weighing 4 lb., has a blast displacement of 0.7 cu.in. per revolution and gives a vacuum of 29¾ in. at 800 r.p.m.

The design, shown in the accompanying figures, comprises a flat cup-shaped casing finished with two or more concentric annular ridges cross-connected by a stop partition with inlet and discharge ports on either side. Into the casing grooves thus formed fit rings cast on an impeller plate properly cut to straddle the casing-groove bridges. This impeller is mounted eccentric with the casing and rocks but does not revolve, being restrained by a back link to the casing. The shaft carries the impeller on an eccentric end pin working in either plain or roller bearings.

The net result is that the rings on the impeller plate roll and slide on the adjacent rings of the casing, as shown in Fig. 2. In *A* the pump is discharging through the right-hand port and drawing through the left: the exterior space is filled. In *B* (90° later) the inner space is completing both discharge and fill while the outer space is beginning both. In *C* (another 90°) the interior space is filled and the exterior one is ready to discharge. In *D* (270°) the inner space is discharging well and beginning suction: the outer space is filling well and completing discharge.

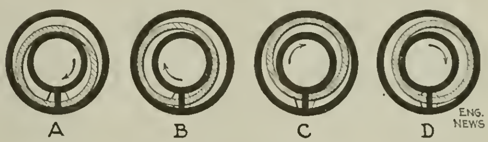

FIG. 2. DIAGRAM SHOWING OPERATION OF MAY-NELSON DISPLACEMENT PUMP

In those designs employing multiples of the simplest arrangement shown, the ports may be connected for multiple or series effect, or they may be used independently as for vacuum and blast simultaneously.

In pumping it is necessary to balance the impeller plate to prevent leakage and friction; as the back of the plate has more effective surface than the grooves, about one-third the operating pressure is admitted to the rear chamber, *A* and *B*, Fig. 1. This is done by adjusting opening of valves in balancing lines run from rear chamber to suction and discharge lines.

High volumetric and mechanical efficiency is claimed though figures are not published. The most of the pumps now in use are in laboratory service but definite operating data seem not to have been secured.

This pump is designed and built by the May-Nelson Manufacturing Co., Washington, D. C.

Traction Engines Are Causing Serious Damage to Maryland Roads, according to a recent newspaper report. The State Roads Commission cannot get local authorities to enforce the law regarding the use of traction engines with cleated wheels; because the farming communities are just now threshing their grain. An injunction to prevent the use of traction engines on state roads without covering the wheel cleats has been refused in Frederick County. The Roads Commission now proposes to equip a traction engine with filler blocks for the wheels, and exhibit it at the county fairs as an object lesson of how damage to the roads may be prevented.

Traveling Cranes for Bridge Wrecking and Erection

In the reconstruction of the Southwark Bridge over the Thames, at London, overhead traveling cranes were used for the removal of the old cast-iron arch ribs and the erection of the new steel arch ribs.

The old bridge (built in 1819) had a center span of 240 ft. and two side spans of 210 ft., each composed of six ribs, and each rib composed of 13 segments or panels weighing 6 to 8 tons each. The ribs were 8 ft. deep at the springing and 6 ft. at the haunches, and were connected by cross frames and diagonal bracing. In the original erection of the ribs, the crown segments were placed first and then the adjacent segments on each side, the segments at the springing being placed last. The bridge was 42 ft. 6 in. wide, with a 28-ft. roadway, and the approach grades were severe. The new bridge will have five arch spans, 240 ft. 6 in. for the center, 131 ft. 9 in. for the intermediate, and 126 ft. 9 in. for the shore spans. It will be 55 ft. wide, with a 35-ft. roadway.

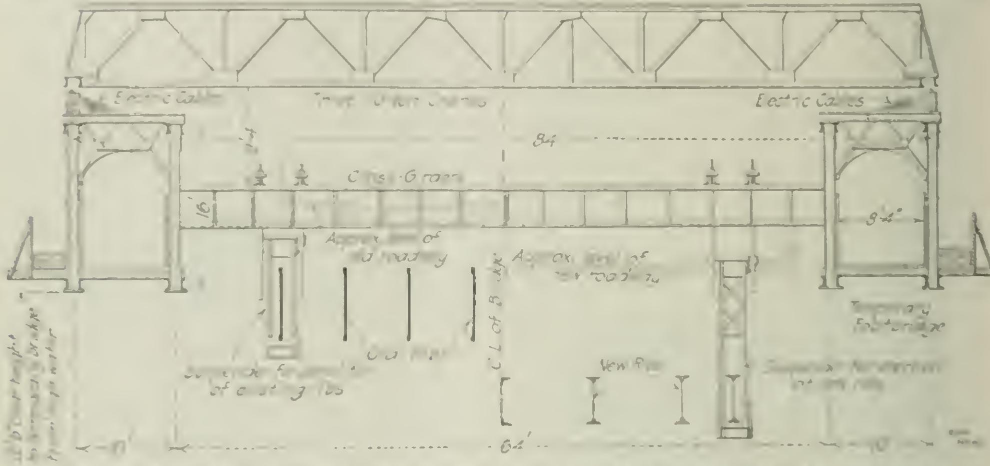

Fig. 1. Temporary Footbridges Carrying Traveling Cranes for Wrecking and Reerecting the Southwark Bridge over the Thames at London

Fig. 2. Method of Supporting the Old Arch Ribs Before Cutting Segments for Their Removal

Along each side of the bridge was erected a [illegible] footbridge, consisting of Warren trusses [illegible] in two parts. These were built on the old bridge and [illegible] out laterally upon the temporary [illegible]. A deck on the footbridge carried the roadway [illegible] and [illegible] the electric cables and water and gas mains. Over the top chord of each outer truss was built a runway beam of two 12x12-in. timbers surmounted by a 70-lb. rail. The two rails were 84 ft. c. to c., and on these ran the grooved wheels of three 10-ton traveling cranes, the girders of which were parallel-chord trusses 7 ft. 9 in. deep.

Posts in the inner truss of each footbridge supported transverse girders, to which were attached hangers holding the arch ribs during the removal of the segments. These girders were 19 ft. 6 in. apart, and connected by diagonal bracing. Across them were laid pairs of 10-in. channels, with washer plates on top for the nuts of the threaded stems of the hangers for the ribs.

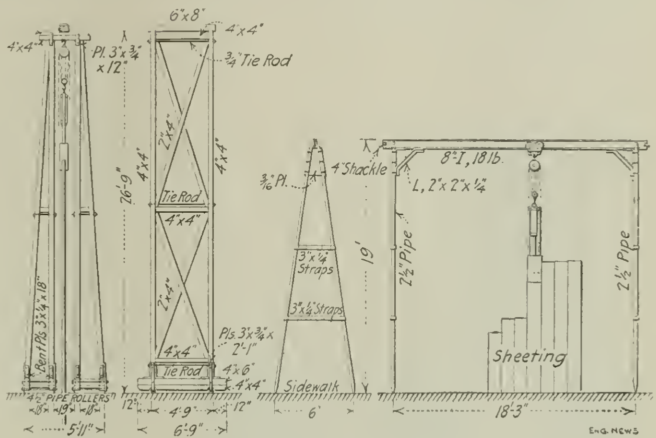
Fig. 1 is a cross-section showing the temporary footbridges, the erecting cranes and the position of the old and new arch ribs. Fig. 2 shows the method of supporting the ribs by hangers and struts. The dotted line on the crown segment (Fig. 2) shows the row of holes drilled to split this segment in two. The other segments were then removed by breaking out the joints. The consulting engineers are Mott & Hay, and Wm. Arrol & Co. have the contract for removing the old and building the new bridge. Our information is condensed from an article in The Engineer, of London, from which also our illustrations are reproduced.

A New Exterior Finish for Surveying Instruments [illegible]

Gantry Frames for Sheetpile Drives

On a section of the new Seventh Ave. subway in New York City the U. S. Realty & Improvement Co. is using a simple gantry frame to support the hammer for driving the sheetpiling along the side of the main trench. The gantry originally used was made up of 4x4-in. timber, as shown in the left-hand sketch herewith. It was a short frame or tower adapted to run on wheels to move it along the trench, the sheetpile hammer being suspended through a chain block from a fixed hook in the top of the top of the frame. After this had been in use a short time a different type of frame, of steel construction, was built. This is shown by the right-hand sketch. Here the hammer is suspended from a trolley running on a longitudinal I-beam which forms the cap of two triangular bents; the frame is not mounted on wheels, but remains in place while the driver is moved along the 16- or 17-ft. length of beam. When this length has been covered the whole frame is picked up and shifted ahead.

The sketch shows the construction of both frames quite clearly and the manner of using them will be apparent. R. K. Smith, superintendent for the contractor on this job, supplied sketches of these rigs.



Gantry Frames for Supporting Sheetpile Hammer

Steel Bridgework in a Severe Fire

A graphic reminder of how destructive is the action of intense fire on structural steelwork is furnished by some views of wreckage of the Central Viaduct and the Nickel Plate railway viaduct at Cleveland. These two viaducts were wrecked on May 25, 1914, by a fire in a lumber yard beneath. A description of the fire and the damage done to the viaducts was published in Engineering News, June 4, 1914, p. 1269, in an article by C. E. Drayer.

Fig. 1 shows a crumpled leg of tower 29-30 of the Central Viaduct. This was pulled out of the ground by the wrecking gang after the iron which had fallen on top of it had been cleared away. Its appearance tends to support the theory that an overheated tower leg initiated the collapse of the viaduct.

Fig. 2 is a view on the deck of the Nickel Plate Viaduct at tower 5. Here the heat was at its greatest intensity. The extreme distortion of girders and bracing shows strikingly.

NOTES

A New Pile Formula which takes into account the relation between the weight of the pile and of the pile hammer, has recently been adopted by R. A. Cummings, Pittsburgh, Penn., in some concrete-pile work in Pitsburgh. The formula is purely empirical and is a development of the "Engineering News" formula, substituting the ratio between weight of pile and weight of hammer for unity in the denominator of that formula. The Cummings formula thus stands:

$$P = \frac{2\,Wh}{s\left(1 + \frac{w}{W}\right)}$$

where

P = Safe load in lb.;
W = Weight of hammer in lb.;
h = Drop of hammer in ft.;
s = Final penetration in in.;
w = Weight of pile in lb.

Evil of Exempting Municipal Utilities from Commission Regulation

We have referred in these columns at various times to the need of placing municipally owned utilities on the same basis as privately owned plants under the supervision of public-utility commissions. One of the latest illustrations of economic loss from duplication of plants, is seen underlying the recent decision of the New York Commission for the Second District, granting the village of Bath authority to construct a municipal electric-light plant. The application to the commission was opposed by the local company, but the report of the commission shows that the authority of the commission was needed only when the village plant should do other than purely public business. The work of constructing the plant had been largely completed and all the commission could do would be to prevent the town from supplying private customers. But the service of the local company was unsatisfactory and could be made only worse without the village's business. The commission was faced with the unfortunate alternative of either having a private company for the private consumers and a public utility for the public load, with inferior service to both, or allowing the municipality to take on the private customers and compel it to give them good service. Had the commission full jurisdiction over the municipal plant from the start, it would have prevented the duplication of work and compelled the private company to give adequate service. The commission recommended that the town purchase the plant of the private company, but the temper of the people is not such as to make that outcome probable.

A Superficially Fireproof Pier

The Philadelphia & Reading Ry. pier fire at Philadelphia, described on another page in this issue, is the fifth destructive pier fire of the year. Already during 1914 the ports of Seattle and Portland on the Pacific, and Glasgow and Portsmouth in Great Britain have suffered considerable loss from the burning up of the structure and contents of wharves. The inflammable contents of the usual warehouse pier, the wide open spaces and the difficulties in fire-fighting, all seem to join together to make particularly destructive any fire which gets a fair start. The four previous fires were in structures which laid no especial claim to being fireproof, so they made particularly good texts from which to preach the necessity for a fireproof construction in all pier and harbor work. The lesson from the Philadelphia fire is somewhat different.

To the untrained eye the Philadelphia pier appeared to be fireproof. It was of steel structure and it had a concrete facade showing from the street. In reality in the condition in which it was last week it was anything but fireproof. The surrounding of the steel columns by concrete had not reached above the floor, and the steel and concrete shell was made practically useless as fireproofing by the presence of a wooden interior balcony and an inflammable, or at least burnable, roof. Finally, there did not appear to have been any attempt to install a sprinkler system of protection.

The fire emphasized the fact that a fireproof building is not a building in which some of the units or members are fire-resisting. It is rather a well designed whole, consisting of individual fire-resisting members so placed as to make extremely difficult the starting of a fire, so built as to succumb but slowly to the attacks of the fire once started, and so protected as to put out the beginning at least of any fire which may evade the first line of protection in arrangement and construction.

The Philadelphia pier was not complete, so any criticism of its construction must be withheld. It should be widely recognized, however, that the building was not a fireproof building in any sense of the word and that its destruction by the fire is no reflection on fireproof buildings or on the quality of concrete and properly protected steel in fireproof structures.

Elevator Gate Accidents in New York City

In remarking, in our issue of Oct. 15, upon the grave dangers to life and limb that lurk at unguarded elevator entrances, we called attention to the multitude of very obvious examples in New York City. This has been strikingly confirmed by figures secured by the Department of Buildings for Rudolph P. Miller, Engineer in Charge of Building-Code Revision for the Board of Aldermen. In the five years 1907-1911, for which records were available, there were 207 fatal accidents—119 on passenger elevators and 88 on freight lifts. Of these, 80% were at shaftings and were preventable. These preventable accidents are well distributed—three in private houses, 19 in apartments, 12 in hotels and clubs, 30 in office buildings, 8 in stores and 23 in factories or lofts. Looked at from another angle, 36 were in buildings six stories high or less; 39 were in buildings of seven to twelve stories, and 20 were where the height was over twenty stories. These are accidents in which fatalities occurred and are not the actual number of deaths, which is somewhat larger. If the same ratios of death to injury prevail here as throughout the country, there were probably nearly two times as many persons injured as were killed.

This situation we should note, however, is one that is being heeded by the present city administration. If the efforts now underway are successfully completed, New York should become a great model of safety in this regard instead of the notorious example of danger.

In the revision of the building code, under the direction of Mr. Miller, it is aimed to incorporate provisions requiring the interlocking of elevator cars and shaft doors so that no shaft gate or door can be opened until the elevator has come to stop at the landing and so that the

car cannot be moved when the door is open. There are some 10,000 elevators in Manhattan alone, with about 100,000 openings. It is planned to spread the required installation of safety interlocks from Jan. 1, 1915, to Apr. 1, 1917, high-lift and high-speed elevators being attended to first.

As proposed up to the present, the use of safety gates inside the cars is not to be made a part of the statute, but is to be covered by rules and regulations of the superintendents of buildings. The most rigid requirements are directed against elevators used for the carrying of persons other than those necessary for safe operation; this includes the majority of so-called freight elevators in the city.

The code provisions, however, as proposed, will go even further. Before the elevators can be installed, erected or altered they must be inspected and licensed. It is also proposed to have them inspected at least once in each three months though, to prevent duplicated effort and to lessen the burden of cost to the city, the certificates of inspection by casualty insurance companies are to be accepted in lieu city inspection. The operator must be competent, experienced and licensed. All accidents are to be promptly reported to the superintendent of buildings, with penalties for failure.

Government Operations at the Panama Canal

Engineers who visited the Panama Canal during its construction were particularly impressed by the fact that the United States, through its engineers, was not only carrying on the actual work of digging the canal by the direct employment of labor without the intervention of any contractor, and was carrying on the civil government of the Canal Zone, but was also carrying on practically all the commercial work required for the supply of the Zone's population.

The commissary stores where the canal employees bought their food, clothing and other supplies were conducted by the army quartermasters and effected an enormous saving to the employees over what would have been necessary had the private enterprise of the Republic of Panama been the sole reliance for supplying the workmen's needs.

Now that the canal has been completed and put into operation, however, it has been found to be necessary that the United States shall continue this work for the benefit of the vessels making use of the canal, as well as for the permanent population of the Zone. Thus, at Panama, the United States is not only operating its canal for the use of the world's shipping, but is keeping store, keeping hotel, running laundries, ice plants, coal depots, oil depots, machine shops and various other commercial enterprises. The government buys coal from the fields of Virginia and West Virginia, transports it to the Isthmus, and sells it at Cristobal at from $5.[illegible] to $5.90 per ton, according to the manner in which it is delivered to the ships, whether from a lighter or alongside the wharf. At Balboa, on the Pacific side of the Isthmus, the price is $1 per ton higher, which is stated to be on account of the cost of transportation of the coal across the Isthmus. This would be at the rate of 2c. per ton per mile for the 50-mile haul—a very liberal figure for transportation cost. Probably this high differential is fixed so that ships passing through the canal will take their supply at Cristobal instead of Balboa, but it brings the coal to rather a high figure for vessels sailing north or south on the Pacific and putting into Balboa for coal without passing through the canal.

Vessels desiring fuel oil can get it at Balboa at present from the Union Oil Co. at $1.30 per barrel, but the government itself will handle the business as soon as its oil-handling plant is completed in January next.

The commissary department of the Panama Canal is now supplying regularly most of the food and wearing apparel used by a population of 50,000 people. These commissary stores are available for the use of ships passing through the canal. The prices charged are generally lower than retail prices in the United States. A large stock of fresh meat, vegetables, fruits, canned groceries, etc., is always kept on hand; and by making advance arrangements, ships can obtain supplies of any article obtainable in the markets of the world. The government laundries are equipped to handle the entire laundry work of a ship in one day's time, so that by forwarding the laundry work by rail from one terminal of the canal to the opposite terminal as soon as the ship arrives in port, the laundry will be ready by the time the ship is ready to clear from the opposite end. The canal repair shops are equipped to do any sort of ship-repair work, and the permanent dry dock, now under construction at Balboa, is large enough to take any vessel that can pass through the canal. Prices of repair work are made on the basis of actual cost plus a percentage to cover overhead expenses.

This remarkable development at Panama, by which the government has undertaken the carrying on of industries and commerce on a large scale which are commonly carried on by private enterprise, has been found to be necessary at Panama to the business-like operation of the canal.

The United States has invested nearly $400,000,000 in a great transportation enterprise. In order to earn as much income as possible on this huge investment, it is necessary that the canal should be made as attractive as possible to the world's shipping. The ability to procure supplies, fuel and repairs for shipping at a reasonable price and to be sure of good service will be as important a factor in encouraging traffic to pass through the canal in preference to other possible routes as will be the safety of transit through the canal and the maintenance of toll rates at moderate figures.

It would, of course, have been possible for the government to have left wholly to private enterprise the care of vessels of fuel, food, water, ice, laundry service and other essentials; but in this limited field it would have been doubtless but a short time before one concern would have secured a monopoly in these respective fields, and it would then have been necessary for the government to undertake the difficult work of regulating prices. It would have involved serious difficulties in dealing with merchants of various nationalities, and the regulation of the character of service rendered in the repair shops, for example, would have been as necessary as the regulation of prices.

This remarkable entrance of the government into the field of commerce and industry at Panama, therefore, has been undertaken as a matter of logical necessity. It is particularly noteworthy that it has been undertaken with

out a hint of public criticism in the United States. The remarkable efficiency attained by Colonel Goethals and his associates in carrying on the canal work has in fact disarmed all criticism. We believe it is an aspect of the engineering work at Panama which deserves even more notice than it has received, and one in which the profession as a whole may take just pride.

Licensing Engineers in Pennsylvania

As reported in our last week's issue, the storm center of agitation concerning state legislation to restrict the practice of engineering appears to have removed from New York to Pennsylvania. A state commission of engineers was appointed by the Governor of Pennsylvania a year ago to consider the question whether state legislation regulating the practice of engineering was advisable in the public interest and this Commission is holding hearings in various cities. It may be of interest at this time briefly to review the agitation of this question in New York and elsewhere, and to indicate the present status of the movement.

In the Western States, legislation to restrict engineering practice has been under discussion for several years in the state engineering societies. A large proportion of the members of these state societies are chiefly interested in land-surveying work; and many of them have been impressed with the poor quality of the work done by many of the men who engage in land surveying and the laying out of drainage and irrigation ditches.

Many who have given careful study to this subject and who oppose any project to subject the entire engineering profession to a license law have freely recognized that there is something to be said for the proposal to subject engineers engaged in some specific branch of work, such as land surveying, to examination and registration. Those who employ surveyors to run farm boundaries, lay out drainage and irrigation ditches, etc., are not well qualified to determine whether a man is or is not competent to perform his work. There is, therefore, some reason for the state stepping in and requiring that those engaging in such tasks should have some minimum degree of qualification for their work. It is, moreover, practicable to determine the qualifications of men to engage in such work as surveying, which requires only a comparatively elementary knowledge of engineering and no very long period of practical experience.

The strongest impetus toward state legislation on this subject, however, came from an organization of engineering employees in New York known as the Technical League. The members of this organization were impressed with the idea that their positions might be bettered and their chances for promotion increased by restricting the practice of engineering to those having a certain minimum degree of education and experience. This organization employed counsel and had bills drafted and introduced in the New York Legislature. These bills, however, related to civil-engineering work solely. As the news went abroad of the introduction of these bills in the legislature, there was a general movement among the engineers of New York to protest against their enactment. Year after year delegations of engineers, including some of the most eminent men in the profession, went to Albany and appeared before the committee in charge of these bills to point out the injury that would result from their enactment. In every case these delegations were successful in having the bills killed by the committee. Not one was ever reported to the legislature.

There were, however, a certain number of engineers who felt that some legislation to regulate the practice of engineering, framed on proper lines, might be desirable There was a larger number who, while they believed that any such legislation would be injurious, felt nevertheless that the pressure to enact such laws would prove in the end too strong to be resisted and that it was better therefore to undertake to frame a bill which would do as little injury as possible.

The first move in this direction was made by the American Society of Civil Engineers. At the annual meeting of this Society, in January, 1911, the members present by almost a unanimous vote, declared that any legislation restricting the practice of engineering was inadvisable. The meeting also, however, adopted the report of a committee of the society's Board of Direction containing a draft of a proposed model engineer's license law which required the licensing not merely of civil engineers but of every man who should undertake to practice professionally any branch of engineering whatsoever, outside of military engineering.

No progress was made, however, in New York or elsewhere toward the enactment of such a law, and in the New York legislature of 1911, 1912 and 1913 bills introduced for this purpose were killed in Committee.

There was organized, in 1913, a joint committee, made up of representatives from each of five of the national engineering societies, for the purpose of investigating the question of state legislation with reference to the practice of enginering, and determining whether an unobjectionable act could be drafted.

Radical differences of opinion developed in the committee as the work proceeded; and notwithstanding more or less mutual concessions, no final agreement on a completed report was ever reached. The principal work in connection with the committee was done by its chairman, the late Alfred Noble. After Mr. Noble's death, the whole matter was dropped.

Meanwhile, however, the changed situation in New York put quite a different face upon the movement to draft a model bill. It had been urged that the joint committee above referred to should complete its work in 1913 so that its bill might be ready for the legislature of 1914, to prevent the enactment of some bill of more injurious character. It developed, however, that the legislature of 1914 took no interest in the project to legislate on engineering practice. No bill on the subject was introduced in the legislature, and apparently the organization which had been so industrious in preparing and pushing bills in previous years had disappeared or had ceased to be active.

While the bill drafted by the joint committee above referred to was supposed to be in theory a model bill applicable to the conditions in any state, it was actually drafted with the conditions existing in New York as the controlling motive.

A copy of this bill was, however, placed in the hands of the Pennsylvania commission above referred to; and this commission, in order to draw discussion from the engineers of the state and have something tangible on which to base discussion, took this bill, redrafted it on

somewhat different form, had it further revised by the bill-drafting experts employed by the State of Pennsylvania, and circulated it among the engineers of that state to obtain their opinions.

The result has been an expression of sentiment from leaders of the profession throughout Pennsylvania, which is, we understand, overwhelmingly against the proposed bill and for the most part against any legislation whatever restricting the practice of engineering. We printed in our last issue a statement by a committee of Philadelphia members of the American Society of Civil Engineers, headed by Prof. Edgar Marburg, giving in detail the reasons why such legislation is opposed.

Space does not permit us to print the numerous other strong letters and statements made by prominent engineers and by committees representing engineering societies in Pennsylvania. These statements, however, will doubtless be printed in full in the report of the Pennsylvania Commission, when that is made up.

The work of this Commission, therefore, will be exceedingly useful. It will doubtless again and again be necessary, in various states, for representative engineers to oppose legislation which seeks to hamper the profession with impracticable restrictions. Again and again in the past the question has arisen, where could a systematic presentation of the arguments against such legislation be found? It will be of great benefit to the profession to have the proceedings of the Pennsylvania State Commission and the testimony before it printed and made available for the use of engineers in other states.

As to the general question of the advantage or disadvantage of legislation restricting the practice of engineering, this has been so fully discussed editorially in past volumes of this journal that it seems unnecessary to take further space at this time. However, it may be said that any attempt to draft a blanket law which will cover the entire work of the engineering profession will result in an unworkable scheme which would break down of its own weight, if it were placed on the statute book. If the practice of engineering is to be regulated by law it must be done by specifying some distinct branch of engineering work, which can be defined in the law, and for which the competency of an engineer can be determined.

In most departments of engineering work, however, it is wholly impracticable to safeguard the public by conducting state examinations of the engineers engaged in it. It is, for example, highly desirable that the public should be guarded from such disasters as boiler explosions. It would be impossible, however, to examine every engineer in the state who might design or construct a steam boiler, and determine his competency for the work, nor could such an examination reach the engineers designing and building boilers elsewhere for sale within the state. The only way the state can secure safe boilers within its borders is to pass such a law as that now being drafted by a committee of the American Society of Mechanical Engineers, specifying how boilers must be designed and built, operated and inspected.

Letters to the Editor

A Vagrant Steam Shovel

Sir—On a recent morning, while walking down Division St. near Ashland Ave., Chicago, I saw a steam shovel trying to cross Division St. The man operating the steam shovel ran the shovel right into a live trolley wire, which burnt off and fell sizzling and spitting to the street. Without losing any time, a helper grabbed a long pole, something like a clothesline pole, and held up the other trolley wire so that the steam shovel could go under it.

Lifting a Trolley Wire Out of Reach of Steam Shovel Boom in a Chicago Street

The whole thing was rather a nervy operation. In the first place the steam shovel ran into the trolley wire without any care at all, just as though no trolley wire was there. In the second place the way that fellow held up the trolley wire with the clothespole and let the steam shovel go under with not more than 2 in. clearance, was rather daring. If the steam shovel had caught the wire it would have burned off and dropped off right near him, and had it touched him it would have put him out of business. I got my camera out of my suitcase and snapped some views, one of which is shown herewith. When the steam shovel was out from under the second or northerly trolley wire it went up the street.

The one thing that impressed me more than anything else was the rank disregard these steam-shovel operators have for the trolley wires. There ought to be a severe penalty for such careless work.

Chicago, Ill., Oct. 15, 1914.

Snow Removal by Artificial Heat

Sir—The method of removing snow by artificial heat suggested in the issue of the Engineering News of Oct. 1, 1914, by Samuel Whinery, is timely and novel, but it

seems to me the same results could be accomplished more readily by the use of direct heat and at much less cost per cubic yard.

Having given a little thought to this subject, I suggest the use of a kind of inverted muffle, mounted on wheels very similar to the apparatus which is used for local heating in making repairs to asphalt pavements. On the muffle could be mounted a tank for fuel oil, and an oil-driven pump could also be mounted on the truck for putting pressure on the tank.

With oil as fuel and directly applied heat, it is probable that 80% of the heat would be available, hence using Mr. Whinery's figures, 1600 B.t.u. would be sufficient to melt 1 cu.ft. of snow, or 13,550,000 B.t.u. would melt 317 cu.yd. At 19,000 B.t.u. per lb., there would be required 713 lb. of fuel, or about 96 gal., which, say, at 5c. per gal., would cost $4.80.

Now, as such a machine would probably be too large for a man to handle efficiently, suppose we consider one of twice that capacity drawn by a single horse; and further, suppose that such an apparatus would cost the same as the boiler, pump, etc., mentioned by Mr. Whinery, viz., $1300; then the cost per cu.yd. would figure out about as follows:

Fixed charges per day	$29.58
Fuel, 192 gal. at 5c. (delivered)	9.60
Driver and horse	6.00
Stoker or engineer	3.00
Laborer or trimmer	2.50
Miscellaneous	2.00
	$52.68

If 634 cu.ft. of snow were melted, the cost per cu.yd. would be	8.30c.
To cover contingencies, add 10%	.83c.
	9.13c.

Or, if we consider the heat efficiency at ⅝ as Mr. Whinery did, the cost would be 8.42 c. per cu.yd.

Of course, the idea might easily be expanded to a number of large machines drawn by a traction engine, or a number of large units each operated by oil or gas engines.

NOTES AND QUERIES

In the article entitled "Pipe Laying Methods on the Narrows Siphon of the Catskill Aqueduct," "Engineering News," Oct. 22, 1914, p. 812, mention was not made of the fact that Long & Miller, 172 Fulton St., New York City, are Consulting Engineers for the contractor, the Merritt-Chapman Derrick & Wrecking Co.

Building Levees with the Hydraulic Dredge

By Jean M. Allen*

In view of the large amount of levee work now contemplated and under construction, and the low cost claimed for the hydraulic fill system, a description of plant and methods used in building levees with hydraulic dredges may be of interest.†

*Consulting engineer, 1139 First National Bank Building, Chicago.

†A previous article on work of this character, by D. C. Yarnell, was published in "Engineering News," June 11, 1914. —Editor.

Discharge Pipe with Bottom Openings

Sand or gravel dredged by the hydraulic process is not carried entirely in suspension by the water in the discharge pipe, but the heavier material settles and flows along the bottom at a velocity much lower than the impelling water. This is specially true if the pipe line is long or the velocity of the discharge water is low. This action can be utilized to build embankments of as steep a slope as 1 on 1, directly from the discharge pipe.

This is accomplished by what are called "shutter pipes," which are lengths of ordinary slip-joint discharge pipe, generally made of No. 10 to 14 sheet steel and in lengths of from 16 to 18 ft., with openings in the bottom, as shown in Fig. 1. These openings are controlled by steel plates or shutters and may be opened or closed at will. A stretch of these pipes is laid on a trestle and the discharge pipe from the dredge is connected to them. When the shutters are opened the sand flows at about the consistency of thick mortar, building up into a steep embankment.

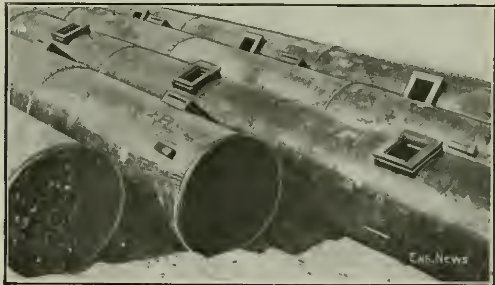

Fig. 1. 20-In. Shore Pipes for Hydraulic Dredge, with Bottom Discharge Openings for Building Levees

The discharge pipe is continued beyond the shutter pipe in order to carry away the surplus water and avoid washing down the levee which has been built. Fig. 2 shows this work and Fig. 3 shows a shutter for a 14-in. pipe. The shutters should be spaced 3 to 4 ft. apart, and should be attached to the pipe with chain or wire, otherwise many will be dropped into the fill and lost.

Dredging Plant for Levees

Many sizes and types of dredges have been used, with discharge pipes 12 to 20 in. diameter, and the cost of the complete plant is from $15,000 to $100,000. Both steam and electrically driven dredges are being used. Some have revolving cutters or water jets to disintegrate the material, but many have neither apparatus. This depends on the compactness of the material to be excavated. In general, any attempt to economize in first cost at the expense of construction or equipment of the dredge will be paid for dearly in subsequent breakdowns and loss of time.

California Dredges—Two powerful and efficient dredges for this class of work on the Sacramento River, are identical except that the "Natoma" is driven by steam and the "West Sacramento" by electricity. Both are built entirely of steel, having hulls 104x35x9 ft. The structural-steel ladder carrying the suction pipe is 50 ft. long, and is equipped with a rotary cutter.

Fig. 2. Dredge Discharge Pipes with Bottom Openings, and Fill Made in This Way for a Levee

The dredging pumps have 20-in. suction and discharge openings and are of nickel-chrome steel. The "Natoma" has a 74-in. runner, driven at 190 r.p.m. by a triple-expansion engine of about 600 hp. Steam at 160 lb. pressure is furnished by two water-tube boilers having a total heating surface of 1500 sq.ft. A double-cylinder 10x12-in. engine drives the cutter, and the winding machinery which handles the spuds and ladder and swings the dredge is operated by a double-cylinder [illegible]-in. engine. A surface condenser receives the exhaust steam from all engines.

The 20-in. pump of the "West Sacramento" has a 50-in. runner and is driven by a 750-hp. motor whose speed may be varied between 300 and 350 r.p.m. The winding machinery has a 75-hp. motor, and the cutter a 150-hp. motor. Three-phase, 60-cycle, alternating current, at 13,000 volts, is brought aboard by a submarine cable and stepped down to 2300 volts.

The cost of the "Natoma" was $[illegible], including [illegible] feet of [illegible] pipe, and the cost of the "West Sacramento" was $[illegible]. The former has deposited several million yards at an average cost of [illegible]c. per cu.yd. After the work was thoroughly organized the average monthly output was about [illegible] cu.yd. per month, and [illegible] for one month [illegible] cu.yd. The dredge was operated 24 hr. a day and 6 days a week, with [illegible] men per shift on the dredge and about 10 men per shift to handle the pipe line.

Mississippi and Missouri River Dredges.—On these rivers, [illegible] and [illegible]-in. dredges are used. The [illegible] to the reluctance of the contractor to build an expensive plant for the small yardage in the contracts offered. Larger machines will hardly be built until projects of greater magnitude are brought forward or unless a great amount of filling is to be done in connection with the levee work.

For a 12-in. dredge, a hull about 80x24x4½ ft. is ample, as the character of the material does not require rotary cutters or heavy suction ladders. The pump is generally belt driven. The ordinary sand and gravel pump of cast-iron construction is not satisfactory, as the abrasive character of the river sand wears cast-iron pump parts with great rapidity; and with pumps having renewable liners there is loss of time in keeping the liners in place and renewing them. The best pump for this kind of dredging is of special design and massive construction, with the shell and runner made of manganese or other special steel. While its first cost is greater, it effects a great saving of operating time, thus increasing the output.

A steam-driven dredge with 12-in. pump should have an engine of 150 to 250 hp. The power for any particular installation is a matter for calculation, taking into consideration the height of discharge, length of line, number of elbows, etc.; also the character of the material to be pumped, which determines the requisite velocity of the water in the discharge pipe. The transmission may be either a leather or a rubber belt or a rope drive, the latter having been found very satisfactory for this duty.

The boilers should be of the externally fired type with large mud drums, both the cylindrical and the Mississippi River types being in general use. The locomotive boiler is not particularly adapted to this work on account of the general turbidity of the feed water. Even boilers of the river type with large mud drums, and frequently blown down, must be washed out every few days. Few of

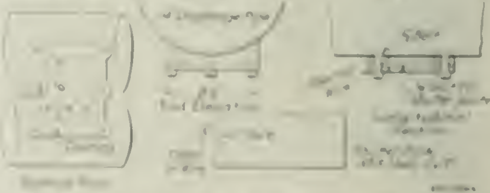

Fig. 3. Bottom Discharge Gates for Suction Pipes of Hydraulic Dredges

these dredges have been equipped with surface condensers, but their use would result in a large saving of time in boiler washing and repairs.

These dredges, working in swift rivers, are held in position by anchors and cables rather than spuds, and [illegible] [illegible] little [illegible] [illegible] to maintain an adequate

supply of sand to the suction pipe. The current keeps the bottom of the river constantly in motion and the material excavated is rapidly replaced by this movement. Instances are common where dredges have pumped for weeks without moving the suction pipe. Thus little winding machinery is required. A double-cylinder single-drum hoist of about 20 hp. is used to raise and lower the suction pipe while the dredge is maneuvered by taking the anchor cables to the winch heads.

The total cost of a 12-in. plant, complete with pipe line, is between $15,000 and $25,000, depending upon the class of machinery and the refinement of construction. Between 25,000 and 50,000 cu.yd. per month would be the probable output, depending upon the length of the pipe line, the layout of the work, river conditions and the skill of the operators.

The dredge with 15-in. pump is built along the same lines as the 12-in., though frequently the pump is directly connected rather than belt driven. In either case, the engine should be compound, to save fuel. Between 250 and 300 hp. is required for a plant of this size, depending upon the conditions mentioned. An efficient engine for medium power is a cross-compound of either the horizontal or marine type. The boilers should have about 2500 sq.ft. of heating surface. If surface condensers are installed, water-tube boilers may be used, otherwise the Mississippi River type is to be preferred. A donkey boiler should be provided for washing the main battery. A hoisting engine handles the suction pipe, but it is desirable to have a deck capstan with independent engines for handling the boat.

The suction pipe is articulated at the end of the dredge either by a swivel elbow or merely by a length of suction hose, and is raised and lowered by tackle suspended from an A-frame over the bow. Its lower end is provided with a suction nozzle, consisting of a cone-shaped head with cross-bars to prevent the entrance of large stones and pieces of wood that would clog the pump. The hull will be about 110x30x5 ft. The 15-in. dredge, complete with all equipment, will cost between $25,000 and $45,000 and its output will be from 60,000 to 125,000 cu.yd. per month. To attain the latter figure, the conditions must be very favorable and the dredge must be operated continuously (24 hr. a day) and with very few delays.

Levee Construction with Dredge

The maximum monthly output of which a dredge is capable is rarely attained in levee work, on account of the large percentage of time lost in shifting pipe, and it is of great importance that experienced men be employed, to reduce this loss to a minimum. As the shutter pipes have to be shifted ahead as each section of the levee is completed, it is advisable to so plan the work that operations can be conducted on two sections simultaneously. The main discharge pipe is provided with a Y-branch and gate valves so that the filling can progress on each section alternately, thus reducing the idle time of the dredge. If this is not possible, sometimes the levee is brought up to the full height but not to full width at the first operation, and then widened with the branch line while extending the main line.

Some contractors use a discharge pipe of larger size than the pump and suction; for instance, an 18-in. discharge pipe for a 15-in. pump, with 15-in. suction pipe. The purpose is to save power by reducing the velocity of water in the line and thus the friction head pumped against. But it is the velocity rather than the quantity of the water that is instrumental in keeping in suspension and transporting such heavy material as coarse sand and gravel. Enlarging the discharge pipe reduces the velocity and causes the sand to settle until the cross-section is reduced and the velocity thus increased to a point where it will again carry the material.

It is better practice to use a discharge pipe of the same size as the pump as far as it connects with the shutter pipe. There it may be enlarged, as it is desired that the sand should settle so that it may be discharged through the shutters. In a high-powered 20-in. dredge on the New York Barge Canal, difficulty was experienced in pumping gravel and small boulders through a long 20-in. discharge line, but upon replacing this with a 16-in. line the material was discharged with ease and the output greatly increased.

Shields or slope-boards, consisting of plates of No. 16 steel about 10 ft. long and 18 in. wide, are frequently used to facilitate the formation of the desired slope. A number of these are inserted, end to end, in the partly formed slope. They prevent the sand from flowing downward until it fills to the top of the plates, when they are pulled out and moved further up the slope.

The hydraulic construction of levees requires considerable skill. The suction-pipe operator must keep a steady and uniform flow of sand in the discharge pipe, and the pipe men must use judgment in opening and closing the shutters to build the embankment to the proper slope; closing some of them if the percentage of sand in the pipe decreases and opening enough of them to discharge water if the slopes need to be flattened out. The handling of the slope boards also requires practice. With a good reliable plant, properly designed to meet local conditions, some remarkable results have been obtained, not only in the low cost per yard but in the character and appearance of the fill.

The operating costs given in the accompanying table are typical for a 15-in. dredge on the Mississippi River,

MONTHLY OPERATING COST—15-IN. HYDRAULIC DREDGE

1 foreman	$150
1 engineman	125
1 engineman	100
2 suction operators, at $100	200
2 oilers, at $60	120
2 firemen, at $70	140
2 coal passers, at $60	120
3 deck hands, at $60	180
1 levee foreman (day)	90
1 levee foreman (night)	70
10 levee laborers, at $60	600
26 Total labor cost per month	$1895
Coal (18 tons per day)	1200
Supplies (rope, oil, packing)	150
Repairs and renewals	200
Office and overhead expenses	200
Insurance (fire and liability)	100
Interest and depreciation (2% on $35,000)	700
Total operating cost per month	$4445

working two 12-hr. shifts. The wages given do not include subsistence. Assuming an output of 75,000 yd. per month the cost is about 6c. per yd.

Division Engineers of the New York State Highway Department have been directed in submitting estimates for construction to include hereafter an approximation of the number of working days required to complete each contract. This, it is expected will enable the Highway Department to specify time limits on contracts more accurately, as the local engineers who work up the field notes are unquestionably in a better position to weigh carefully the elements which enter into the building of a piece of road than the office force are.

Failure of a Basement Retaining Wall During Construction

By Henry Blood*

On Oct. 7, a portion of the Morrison St. retaining wall of the new Meier & Frank department store, in Portland, Ore., collapsed, causing the street to cave in for a length of 62 ft. and flooding the excavation with water.

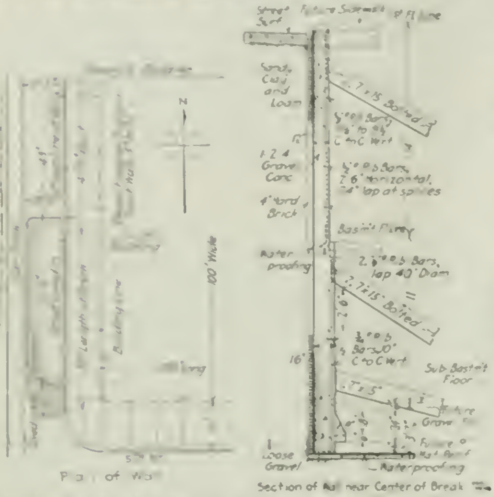

Fig. 1. Plan and Section of Retaining Wall Which Failed at Portland, Ore.

The building is under construction. It will be 100x200 ft. in plan, of steel-frame construction, with reinforced-concrete floor slabs, and will have a basement and sub-basement, both to be used for mercantile purposes. The basement space is 115x224 ft. outside dimensions. The height of the sub-basement is 11 ft., that of the basement is 14 ft. The sub-basement floor is laid directly on the soil, which consists of good gravel. It is to be composed of a 4-in. plain slab laid on the soil, and carefully leveled on top for the waterproofing, a 9-in. reinforced mat on the waterproofing, 2 ft. of gravel fill, and finally 6 in. of concrete with wood sleepers and a wood floor. Only the 4-in. slab on the earth had been laid at the time of the collapse.

The wall was designed as a vertical slab with vertical reinforcing, to be held against the lateral pressure of the street fill by the sub-basement, basement floors, and sidewalk. It varies from 16 in. in thickness below the basement floor to 12 in. at the top, the reinforcing varying as shown in the section through the wall in Fig. 1. The concrete is a 1 : 2 : 4 mix. It was about six weeks old at the bottom and four weeks at the top, at the time of accident. On the outside of the walls there is a layer of waterproofing membrane and 4 in. of hard brick. This may be seen in the view taken from the street (Fig. 4).

The wall is 27 ft. high at the east building line, on Morrison St., 33 ft. at the west end and about 28 ft. at the center of the break. It was braced with three lines of shores, one above the other, spaced about 12 ft. apart horizontally. The upper two rows consist of two 7x15-in. seasoned Douglas-fir sticks, bolted together and well braced laterally. They show clearly in the views in Figs. 2 and 3. The upper end is set into the concrete about an inch, and the lower end firmly held. The center of the upper shores is from 3 to 4 ft. below the top of wall, the middle row hardly half way up the wall. The lower set of braces was made of single 7x15-in. timbers and simply placed to bear against the wall with thin pieces of plank between them and the wall, relying on friction to hold them in place. They are from 4 ft. 9 in. to 5 ft. above the bottom of wall still standing, and inclined at an angle of approximately 15° to the horizontal. It could not be ascertained whether there were any at the point where the break occurred, but the superintendent states that there were.

There is a 6-in. water main and a 20-in. glazed tile sewer

*Bureau of Buildings, City Hall, Portland, Ore.

Fig. 2. Near View from the Inside, Showing Bracing and the Bottom of Wall Which Failed

Fig. 3. View Taken Day after Failure, Showing Broken Wall at Bottom

on this side of the street. The sewer is about 11 ft. below the street opposite the break.

The inspector for the architects stated that the wall had moved in $1\frac{1}{2}$ to 2 in. at the point of failure about Sept. 18. The pavement began to settle slightly, and readings were taken by the Department of Public Works on the 25th and 28th, showing a maximum settlement of

Fig. 4. Looking Alongside Morrison St. after Collapse

(Brick outside facing of concrete wall on right; sewer trench cut on left.)

$1\frac{3}{4}$ in. Later it was reported that the sewer was leaking, and a crew was sent on Oct. 2 to uncover and repair it. A trench was made close to the outer rail of the car track, as the sewer lies in this position. It was found that a settlement of about 9 in. had occurred at the worst point. The trench had not been refilled and its vertical side may be seen in Fig. 4.

Water coming over the wall, according to the superintendent's statement, and cracks opening in its lower portion, gave the workmen sufficient warning to escape. An irregular piece of wall about 55 ft. long and 17 ft. high at the highest point was torn loose and forced inward, the movement beginning at the bottom of the wall (Fig. 3); it lay on a heap of earth and timber with the bottom edge about 20 ft. from the wall. The reinforcing rods pulled out where they were lapped at the basement-floor line, and large cracks were formed in the surrounding wall. The street caved in from the wall to nearer car track for a length of 62 ft., beginning 43 ft. from the west end of building, leaving a deep hole. The pavement dropped in for 51 ft. 6 in. (Fig. 4). Before the water main could be shut off it had let 2 ft. of water into the excavation. Car service in front of the site had to be discontinued, and cannot be resumed for some time yet.

At the time of accident no floor framing or any steelwork was in place; the sub-basement floor, gravel fill, and 9-in. mat had not been placed; and the wall simply stood on the waterproofiing, with nothing on the lot side to resist pressure from the street fill except the struts. It can be seen by reference to the wall section that there was no steel to resist stresses due to cantilever action. The wall was not designed for such action; but was entirely safe as a slab for a heavy earth pressure, even at the age it had reached. The concrete was good and steel accurately placed. It will also be noted that there were no horizontal timbers along the wall.

A large portion of the wall will have to be rebuilt. It is quite probable that the entire Morrison St. end will be replaced. The new wall will be made somewhat heavier. It will not be put in until the mat is all in place, and of sufficient age to be used for support. The bottom will then be held with horizontal shores. The bracing will probably be set closer together, and the lower ends will have a firmer seat in the mat than was the case when the accident occurred.

The accompanying photographs were made by the Department of Public Works. In connection with the drawing they illustrate the conditions quite clearly.

The Savings of Electric Traction over steam on the Butte, Anaconda & Pacific Ry. (described in "Engineering News," Aug. 15, 1912, Mar. 19, Apr. 2, and June 2, 1914), were reported at a meeting of the American Institute of Electrical Engineers in Spokane, Sept. 9, 1914, by J. B. Cox. The number of trains had decreased 25% but 35% more tonnage was hauled per train. Repairs had dropped 26% and engine-house expenses 38%. For energy alone \$150,727 was saved. The reduction in trainmen's wages was \$31,146. The total cost of conversion to electric traction was \$1,201,000, making the total savings some 20% on the cost.

A Storm on Lake Michigan, Oct. 24, marooned 11 workmen on the intake crib of the new water-works intake for the city of Milwaukee. They were rescued by a member of the United States Life Saving crew, who swam out to them from a motorboat with a life line. On Apr. 20, 1893, 21 men lost their lives on a water-works crib under construction on the Milwaukee waterfront. Information regarding the recent storm came to us after the note by Mr. Warren printed on p. 897

How Fire Wrecks Unprotected Structural Steel

We briefly described on p. 862 of our last week's issue the burning of a new pier shed of the Philadelphia & Reading Ry. on the Delaware River at Philadelphia on the evening of Oct. 15. The accompanying upper view shows a photograph of the interior of the wrecked pier, looking toward the street, and the lower view shows the reinforced-concrete front from the street side. The lesson has been many times impressed on the engineering profession that steel structural members, unless protected by fireproofing material, are much more vulnerable to the attack of flames than are heavy wooden posts and beams. The wreck of this pier shed is simply another illustration of the same fact.

Below the floor level the pier was a substantial concrete structure with a concrete floor, and the fire left it practically uninjured. The entire steel superstructure, however, was in a very few minutes converted into a mass of tangled scrap exceedingly difficult and expensive to cut up and remove. The work is being accomplished with the aid of oxy-acetylene torches.

The fact that a solid wooden post resists fire far better than bare steel is again well illustrated at one point of this pier where a short wooden post about 10 in. square, used as some temporary support, was in place at the time of the fire. The outside of this post was charred only to the depth of half to three-quarters of an inch, and the balance of the post cross-section was sound and uninjured. As most of our readers are aware, it was this substantial resistance to fire of solid wooden posts and beams which brought the New England factory slow-burning method of construction into being.

While the steel pier shed had been completed and a small amount of freight had been stored on the pier at

Interior and Exterior Views of Burned Philadelphia & Reading R.R. Pier, Philadelphia

the time the fire occurred, the reinforced-concrete front of the pier, facing on Delaware Ave., still lacked a few days' work of completion. At one end, some of the forms were still in place, while the concrete protection of the steelwork at the central arch portal had not yet been poured. This reinforced concrete withstood the exposure in admirable fashion, as may be judged from the accompanying photograph. It is noteworthy also that the row of small windows above the projecting canopy roof framework on the left-hand side, seen in the background in Fig. 2, had been filled with wired glass. This glass had been heated so intensely as to render it opaque, but every pane remained intact throughout the fire.

Difficulties Being Met in Constructing the New Intake Tunnel at Milwaukee

By Lee G. Warren*

In the prosecution of the construction of the Linwood Avenue Intake Tunnel, under Lake Michigan, at Milwaukee, Wis., which was described in Engineering News, June 18, 1914, p. 1364, two recent and very serious collapses of the unlined roof have occurred. This tunnel, which is being built to give an increased water-supply for the city, has a circular cross-section, 12 ft. inside diameter, 15 ft. outside diameter. The lining is reinforced concrete having 1 : 2 : 4 proportion, the reinforcing being ¾-in. round steel bars. The tunnel when completed will have a length of 4000 ft.

Since June 1 of this year, or at Sta. 18+00, the contractor had encountered firm shale, having little difficulty in holding the roof, while advancing the heading on a daily average of 10 ft. But on Sept. 27, the unlined roof collapsed at Sta. 27+95 to 28+04, carrying down four 12x12-in. roof timbers, set at 4-ft. intervals. The hole resulting was 15x9 ft. at the bottom, 7x8 ft. at the top, and 15 ft. high, above the roof timbers. The material coming from the hole consisted of gravel, boulders, saturated clay and disintegrated shale, the quantity of water being very small. None of the workmen was injured, as a preliminary warning was given by the cracking and scaling off from the roof, and the settling of the timbers. The fall was caused, no doubt, by the saturated condition of this pocket and by the consequent overloading of the timbers. The nearest borings, 1100 ft. distant, showed shale at the depth at which the collapse occurred, 38 ft. below the lake bottom. The depth of the lake at this point is 30 ft. The roof timbers were replaced and the hole at the point of collapse was tightly packed with cribbing, after a 36-hr. battle to install them. An examination of the strata of the hole showed 14 ft. and 6 in. of mixed and soft shale, lying in thin layers, above the roof line. The roof of the hole consisted of hardpan, which held its position. Between the hardpan and the shale, there was a water course about 6 in. in depth and extending the width of the tunnel. Water, in a small volume was flowing from both sides parallel to the tunnel axis into the hole from this water course.

On Oct. 12, another roof collapse occurred at Sta. 29+09, bringing down a mixture of gravel, sand, clay, boulders and broken shale. With the fall came a 3-in. stream of water which continued for 2 hr. The same kind of preliminary warnings as given prior to the roof collapse on Sept. 27, were given for this collapse. This hole measured 6 ft. long and 12 ft. wide at the bottom, 3 ft. long and 10 ft. wide at the top and 18 ft. high above the normal timber line. The lower 14 ft. of the hole consisted of mixed and soft shale. Above this shale, there was 1 ft. of hardpan, the hardpan having collapsed after it had become water-soaked and softened. As soon as the collapse occurred, the tunnel was placed under air pressure, which was gradually increased to 26 lb. per sq. in. A pressure of 10 lb. per sq.in. was secured within 2 hr. and 10 min., two compressors operating, the air locks being located at Sta. 0+85. Thirty hours after the pressure was applied the compressors were stopped, the pressure then being 26 lb. per sq.in. Eleven hours after the compressors were stopped, the pressure gage showed 17½ lb. per sq.in., indicating that the tunnel was reasonably air-tight. No one was injured by this fall.

The hole caused by this roof collapse was firmly cribbed after a 30-hr. struggle. The tunnel was entirely released from air pressure 42 hr. after the collapse. Mining and concreting operations were then resumed, light charges being used in blasting.

Orders were issued to the contractor to install a safety bulkhead within 200 ft. of the heading. Plans and preparations have been completed for installing a safety bulkhead composed of 10x10-in. tongue-and-grooved timbers, reinforced with one 20-lb. 6-in. I-beam and two 35-lb. 10-in. I-beams. It will have a 4x6-ft. material door composed of ¾-in. steel and will also have a 3x3-ft. man door composed of ¾-in. steel. The former door will hang on rollers and close by sliding. The latter door will be hinged. The bulkhead will have its outside perimeter resting in a 6-in. groove in the concrete lining. The present air lock will be used in conjunction with the bulkhead.

Joseph Hanreddy & Co., of Chicago, Ill., is constructing the tunnel. Geo. F. Staal is City Engineer, under whose charge the work is being done. The writer is Resident Engineer for the city, supervising construction.

*Resident Engineer, Linwood Ave. Tunnel, Milwaukee, Wis.

Automobile Exports in the year ending June 30, 1914, are reported by the U. S. Department of Commerce to have been distributed as follows:

A New Process of Metal Coating

A remarkable new process of coating metal, which was brought out by a Swiss inventor, Schoop, some two years ago, has now been reduced to commercial form, and promises to have industrial applications of great importance. The novel character of this new process may be realized, when it is stated that it is possible by it to apply a metal coating not merely to another metal surface, but to articles of wood, plaster, cement, paper, leather, glass, porcelain and even cloth. What is still more important is that a great variety of metals and alloys can be thus applied. The coating may be extremely thin or as thick as desired; the process is applicable either for delicate decorative work or for the rough work of coating iron and steel articles or sheets with some non-corrosive covering, such as lead, zinc, tin or copper.

According to the present outlook, it should be possible to treat many articles of steel and iron now protected by paint, which requires frequent renewal, with a coating of lead or zinc or brass applied by the Schoop process at a cost which will be less than the ultimate cost of repeated applications of paint.

There are only two metal-coating processes now in extensive commercial use—electroplating and dipping.* The electroplating process is chiefly used for coating metal articles with gold, silver or nickel. Iron sheets and pipes are coated with zinc by dipping (the so-called galvanizing process), and also with tin. A very serious drawback of the electroplating process is that the film of metal which is deposited is chemically pure, and therefore comparatively soft, so that it rapidly wears away. Were it possible to apply a coating of gold or silver or nickel alloy instead of the pure metal, the plating would wear several times as long. Further than this, the electroplating process is an expensive one to operate, and is, therefore, confined to articles of considerable value.

The Schoop process of metal coating, now to be described, operates in a manner entirely different from anything ever tried in the art. Briefly described, a thin wire composed of the metal of which a coating is to be applied is melted in the flame of an oxy-hydrogen blowpipe, and at the instant of melting is subjected to a powerful blast of compressed air. The article to be coated is held in this air blast a few inches away from the oxyhydrogen flame; the minute particles of metal carried by the blast build up a coating that adheres as firmly as a coat of tin or zinc to a plate of steel dipped in a molten bath. It is, of course, necessary that the surface to be coated shall be perfectly clean. Even the slightest film of grease prevents adherence. In this, of course, this process is similar to other metal-coating processes in which it is common practice to pickle the metal to be coated before it is treated.

The amazing and well nigh incredible thing about the Schoop process is that the particles of metal discharged in the air blast should adhere and form a dense, smooth coating, instead of flying off as dust. While the wire is melted in the oxy-hydrogen jet, the molten metal is instantly congealed by the blast of compressed air, and the particles of metal, as they strike the object to be coated, are at so low a temperature that they can be received on the hand for a moment without injury. In fact, the metal coating can be applied to such inflammable materials as cloth, paper, wood and even celluloid, or the phosphorus-coated end of a match. It is evident, therefore, that the particles of metal on the surface to be coated are in the solid and not in the molten state. They are, however, moving with an enormous velocity, some 3000 ft. per sec.

The invention, as now developed, is radically changed from its original form. At first, the metal to be used for coating was melted and held in a reservoir. A fine jet of this molten metal was atomized by air pressure and directed against the surface to be coated. In that form the apparatus was clumsy, and the process was only adapted to spraying lead and tin. In a later apparatus, fine metallic dust was simultaneously acted upon by heat and air pressure. Some success was attained with this form of apparatus, but the high cost of manufactured metallic dust and its tendency to oxidize rapidly, restricted the use of this form of apparatus chiefly to zinc.

The present form of apparatus is termed a spraying pistol. While it has been used in Europe for some time, it was introduced into this country only six months ago. It is a portable hand tool, weighing only 7½ lb. The pistol is connected by small tubes with reservoirs supply

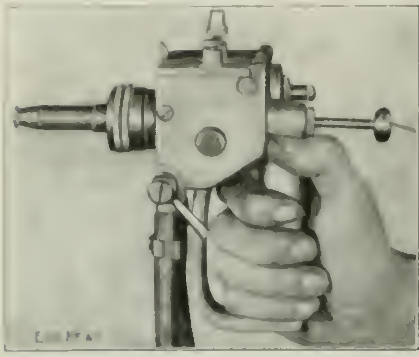

Fig. 1 The Schoop Metal Spraying Pistol

Fig. 2 Coating an Iron Casting with Copper with the Schoop Pistol

*The [illegible] process for coating [illegible] with [illegible] [illegible] [illegible] [illegible] [illegible]

ing oxygen, hydrogen and compressed air. The compressed-air blast nozzle is concentric with the oxy-hydrogen burner. The issuing compressed air drives a tiny turbine which propels friction wheels that feed the wire into the flame.

In a paper on the Schoop process*, by R. K. Morcom, before the Institute of Metals†, the process is thus described:

The essential parts of the machine, or "pistol," as it is called, are a combined melting and spraying jet and a feed mechanism. The metal, in the form of rod or wire, is fed to the melting-flame. The flame can be formed by coal-gas, water-gas, acetylene, hydrogen, etc., burning in air or oxygen according to the metal used. The gases are supplied at such pressures as to prevent blowing out and to insure a highly deoxidizing flame. The spraying-jet can be of carbon dioxide, nitrogen, air, steam, etc.; it is fed at such a pressure as to produce a sufficiently high velocity for successful coating.

To obtain the best adhesion, the surface on to which the metal is sprayed must be thoroughly clean and of an open nature to give a key for the deposit. Sand-blasting with sharp sand has been found best. Shot gives too polished a surface. Such surfaces as fabrics, wood, unglazed earthenware, and asbestos require only freedom from grease, as their surfaces give a natural key.

As at present constructed, the standard pistol uses about 0.55 to 0.6 cu.ft. per minute for every 1 lb. per sq.in. air pressure, so that with an air supply at 80 lb. per sq.in., which is a very suitable figure for ordinary spraying, the air consumption will be from 45 to 50 cu.ft. per minute. The mass of this will be from 830 to 920 grams, and the mass of metal sprayed by this air will be from about 8 grams in the case of iron to about 200 grams in the case of lead.

The action of deposition is probably a complex one. The minute particles of solid metal are driven with such force against the object that, in some cases, they fuse, but, owing to their small relative size, are promptly chilled by the object to which they adhere. If any of the particles are molten or gaseous, they will adhere. In addition, the suddenly chilled particles are possibly, or even probably, in the state of unstable equilibrium found in "Prince Rupert's Drops," and act like so many minute bombs, bursting on impact into almost molecular dimensions, and penetrating the smallest cracks and fissures of the object.

The process requires some care in manipulation, as, by varying the conditions, it is possible to spray porous or non-

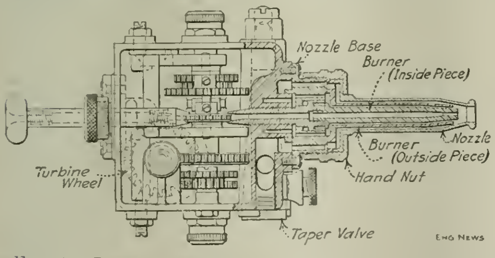

Fig. 3. Longitudinal Section through Spraying Pistol

porous coatings, and, with some metals anything from a pure metal to a pure oxide. With care, however, nonporous, oxide-free, adherent coatings can be produced of almost any metal on almost any solid.

In addition to metals it is possible to spray fusible nonmetals, or, by stranded wires, alloys of metals or mixture of metals with nonmetals.

The possibilities of the Schoop metal-coating process are so many that time has only permitted a few of them to be commercially investigated. So far, three principal lines have been followed: First, to preserve from corrosion, moisture or chemical action, various objects of wood, paper, stone, cement, iron and steel; second, to use the process for decorative purposes; third, to use the process for copying. As already noted, a thin film of grease on a surface prevents the adherence of the coating. It is possible in this way to make, very quickly and cheaply, perfect replicas of a coin, medal or other object in relief. Of great interest to engineers is the use of the process for covering iron and steel with some non-corrodible metal. We are informed that it is possible to carry out this work at very moderate cost. Those controlling the process say, "The cost of operating the Schoop process in the United States has been carefully ascertained, through experience with the appliance during the last six months. The seven metals most commonly used for protecting or decorating surfaces are lead, zinc, aluminum, brass, German silver, bronze and copper. When the oxygen and hydrogen used are purchased in small quantities in usual containers, the cost of spraying lead, including the cost of wire, compressed air and labor, is between 1 and 2c. per sq.ft., and one pound of lead can be sprayed in less than a minute. The other metal coatings vary with the initial price of raw material and its relative hardness. When the process is used on a large scale and the oxygen and hydrogen are either generated on the premises or purchased at wholesale, a considerable saving from the above figures can be effected."

The use of the Schoop process in the United States is controlled by the Metal Coating Co. of America, with offices in the People's Gas Bldg., Chicago. The president of the company is John Calder, formerly associate manager of the Cadillac Motor Car Co., of Detroit.

*"Engineering," Sept. 25.

†See British patent to Schoop, 1910, No. 5712, 1911, No. 21,066; and to Morf, 1912, No. 2801.

NEWS NOTES

Floods Resulting From a Rainfall of 5 In. In 3 Hr. caused the death by drowning of about 20 persons in San Antonio, Tex., Oct. 23. The property loss is estimated at $150,000.

A 24-In. Water Main Burst in Jackson, Miss., Oct. 13. The main had been installed but about two weeks as a part of the new water-works. The failure is laid to a defect in the pipe

The Derailment of a Passenger Train on the Missouri, Kansas & Texas Ry., Oct. 19, near Bartlett, Tex., caused the death of the engineman and fireman, and injuries to 15 passengers.

A Fall of Rock and Earth at the quarry of the R. F. Baker Rock Crushing Co., at Bluefield, W. Va., Oct. 19, killed six workmen. The fall came without warning and the men were so deeply buried that blasting had to be resorted to in recovering the bodies.

The Serious Accident at Tiptonford, Mo., Aug. 5, 1914, in which a gasoline motor car on the Missouri & North Arkansas Ry. ran head on into a passenger train on the Kansas City Southern R.R., resulting in the death of 45 persons was caused by a poor signal system and an apparent misunderstanding of orders, according to the recently issued report of the Interstate Commerce Commission.

A Fast Express Train Was Derailed on the Pennsylvania R.R., 38 miles west of Glen Union, Penn., Oct. 18. The train is known as No. 52, or the Buffalo-Philadelphia express. The derailment was caused by the breaking of an axle on the tender, while the train was running at a speed of 45 mi. per hr. The entire train of three coaches, three Pullman cars, a dining car and a baggage car left the rails, and the engine, tender and baggage car rolled down a 6-ft. embankment. The train was composed of all steel cars and no one of the 100 or more passengers was seriously injured.

Extensive Highway Construction in California—The California State Highway Commission announces that 202 miles of road have been completed and accepted, and that 615.7 miles have been partially completed since bonds in the amount

[illegible] for this [illegible] in [illegible] for [illegible] have been [illegible] and [illegible] miles have been placed under contract.

Four Commercial Attachés have been appointed by the United States Department of Commerce to travel through [illegible] countries and report upon commercial opportunities for American business firms in those countries. The [illegible] are as follows: Messrs. [illegible] for [illegible] Hall, for [illegible] Verne L. Havens, for [illegible] Chile [illegible] for Rio de Janeiro, Brazil. Mr. Havens's appointment is noted in our personal columns on another page of this issue.

The Watervliet Water Supply Project has been approved by the New York Conservation Commission, provided the supply is filtered in accordance with an advocated [illegible] [illegible] with [illegible]. This project was noted in Engineering News, Feb. 26, 1914, p. [illegible] and Mar. 19, 1914, p. [illegible] [illegible] attaches to its approval on account of its interference with the [illegible] project fostered by the commission [illegible] of Watervliet and neighboring communities (see "Engineering News," July 16, 1914, p. 158.)

Increase in Fares on the San Francisco-Alameda County [illegible] lines of the Southern Pacific Co. have recently been denied by the California Railroad Commission, on the grounds that such increase would result in the confiscation of large property values created by the earlier rates voluntarily fixed by the company. The commission is of the opinion that a return on cost of electrification and other improvements should be eventually secured though not necessarily at present since the improvements were voluntarily undertaken.

A Receiver Has Been Appointed for the Brazil Railway Co. and its subsidiary, the Madeira-Mamoré Railway Co., which are both incorporated under the laws of the State of Maine. The Receiver is W. Cameron Forbes, former Governor-General of the Philippine Islands. It is reported that most of the stock and bonds are owned abroad. This adds another chapter to the interesting history of the Madeira-Mamoré Ry., for details of which the reader is referred to "Engineering News," Oct. 17, 1907, Oct. 24, 1907, Oct. 31, 1907, Mar. 26, 1908, Nov. 12, 1908, Sept. 26, 1912.

The Diversion of Schoharie Creek into Esopus Creek to give sufficient water to fill the Catskill Aqueduct, New York City, has been authorized by the New York State Conservation Commission. We are indebted to Alfred D. Flinn, Deputy Chief Engineer of the Board of Water Supply of the City of New York, for the following concise description of the project:

The city proposes to divert from the upper part of Schoharie Creek, above a dam at or near Prattsville, Greene County, N. Y., sufficient water to fill the Catskill Aqueduct. Only about half the capacity of the Catskill Aqueduct can be obtained from the Esopus Creek, the development of which is now nearly completed. A large reservoir will be created by a dam near Prattsville from which the water will be diverted into the Esopus watershed and Ashokan reservoir by means of a tunnel about ten miles long through one of the ranges of the Catskill Mts. Approximately 310 sq. mi. of watershed of the Schoharie Creek will be utilized.

A Systematic Survey of the City of Chicago has been begun. This work is being done by the Division of Surveys which was organized early last year with T. C. Phillips, Engineer of Surveys, in charge. The initial appropriation for the year 1913 was $22,000. This specifically provided for a survey of all public streets and alleys entering into or crossing the right of way of the Chicago & Western Indiana R.R., with the object of disclosing to what extent the railway had encroached on public ground. The survey of this railway [illegible] right-of-way between Polk and [illegible] St. showed encroachments to the extent of [illegible] sq.ft. of public property, [illegible] in value [illegible]. This, however, is only a small part of the encroachments disclosed by surveys of the [illegible] Division in the course of the year. The value of [illegible] [illegible] [illegible]. The [illegible] of the [illegible] Division of Surveys should be the making of a comprehensive survey of the entire city [illegible] [illegible] in cities of New York, Philadelphia, Baltimore and Cincinnati.—From the 1913 Annual Report of the Department of Public Works of Chicago, Ill.

Fatalities in the Metal Mining Industry [illegible] A. H. Fay, Mining Engineer, U. S. Bureau of Mines, as follows:

	Men employed	Men killed	Fatalities per 1000
1911	[illegible]	[illegible]	[illegible]
1912	[illegible]	[illegible]	[illegible]
1913	[illegible]	[illegible]	[illegible]

The important mining states showing a continuous reduction of fatality rates during 1911, 1912 and 1913 are Idaho, Michigan, Montana, Nevada, New Jersey, South Dakota and Utah—representing in 1913, [illegible] of the mining [illegible]. Alaska, Alabama, Colorado, New York, Oklahoma, Tennessee, Wisconsin and Wyoming showed a decreased rate only in 1913 over 1912. These reductions are attributed to the introduction of safety appliances, better supervision and a more strict enforcement of rules and regulations of the mining companies and a closer observance of state laws. Practically all of the larger companies, and many of the smaller ones, have inaugurated the "safety-first" movement with good results. [illegible] have been [illegible] of short duration and have been kept out of the "serious" or "fatal" classes.

The "Third" Lock at St. Mary's Falls Canal, Sault Ste. Marie, Mich., was opened for traffic without any special formalities on Oct. 21. This lock, which is 360 ft. longer than the Panama locks, forms an important addition to the present lockage facilities between Lakes Superior and Huron.

The first appropriation for the work was made in [illegible], and a coffer-dam surrounding the site was completed in [illegible] when a contract was let for the excavation which required two years to complete. The masonry was built in 1912 and 1913, and the machinery and gates were completed this year. The lock chamber is [illegible] ft. wide by [illegible] ft. in length between the inner gates. There are two pairs of operating gates at each end of the lock to guard against accidents, making the total length of the masonry [illegible] ft. The sidewalls are [illegible] ft. high above the floor, those at the ends, forming the gate abutments, are 36 ft. thick, and the sidewalls in the chamber are 26 ft. thick at the base and 12 ft. at the top. The four pairs of operating gates are of steel and the two [illegible] of guard gates (for unwatering the lock when necessary) are of Western fir. The machinery is operated electrically.

On the first lockage, upbound, the U. S. steamer "[illegible]," the inspection steamer of Col. Mason M. Patrick, the Engineer Officer of the Detroit District, entered the lock first, and was followed by the U. S. steamer "Alfred Noble," the U. S. revenue cutter "Mackinac," the tugs "L. C. Sabin," "S. C. Schenck," "Illinois," and "James Edward." These were followed by the freight steamer "Alva C. Dinkey," which has a length of 600 ft. and beam of [illegible] ft. In the first down lockage were two loaded steamers, the "James A. Farrell" and the "Richard Trimble," both 600 ft. long by [illegible] ft. beam, and loaded with iron ore. The combined cargoes was [illegible] tons, probably the largest lockage ever made in point of tonnage.

The traffic through all the locks at Sault Ste. Marie last year was 79,718,344 net tons of freight, with an average value of $11 per ton, or total valuation of about $866,000,000. The lock work was described in "Engineering News," March [illegible], and April 23, 1914.

The New Union Station at Kansas City, Mo., is to be opened to traffic on Oct. 31. It is located in a different part of the city from the old station and is on a terminal or belt line affording connections with all the railways entering the city. There are 16 station tracks (with room for [illegible]) and two thoroughfare tracks; the station tracks are in pairs, [illegible] and [illegible] ft. c. to c., of sufficient length for two trains of 6 to 11 cars each. While all are through tracks, the station is to be operated on the double-end system, certain roads entering and leaving at one end and the others at the opposite end. Mail and express will be handled at both ends, but mainly at the west end. Baggage will be handled by elevators serving the platforms and a transverse subway. There are 11 railways in all, with about [illegible] trains per 24 hr.

The station building has its main floor at the street level, with track floor beneath and two floors above for offices. It is a low structure, no attempt having been made to utilize the site for a general office building. Its special feature is that the waiting room ([illegible] ft.) extends as a one-story structure across the tracks. On each side of this room is a corridor, with stairways to the platforms. Outgoing passengers reach the stairways by doorways (with ticket inspectors) at the sides of the waiting room. Incoming passengers pass out along the corridors, without entering the waiting room.

The tracks are covered by a steel-frame train-shed about [illegible] ft., the roof being carried by trusses of 41 ft. span on columns spaced [illegible] ft. apart along the platforms. Over each pair of tracks is an opening [illegible] ft. wide for light and ventilation. The clear height from rail to bottom of truss is about 16 ft.

About [illegible] west of the station is the engine terminal with roundhouse, coaling station, ashpit, etc. Here also is the coach yard, having stub tracks in groups of five, with capacity for [illegible] cars on the cleaning tracks and 16 on the repair tracks. This yard is paved and equipped to supply

water, compressed air, steam, gas and electric current for charging batteries.

The station with its tracks and accessories is said to represent an expenditure of about $25,000,000; the total cost, including the new approaches, etc., is put at nearly $40,000,000. The entire terminal is owned and operated by the Kansas City Terminal Co., representing the several roads. John V. Hanna is Chief Engineer, and A. C. Everham, Assistant Chief Engineer; Jarvis Hunt, Architect. The entire terminal system was described and illustrated very fully in our issue of Aug. 7, 1913; the tunnel carrying O. K. Creek across the station site, July 31, 1913; and the trainshed, Oct. 8, 1914.

PERSONALS

Mr. L. M. Dooley, former Inspector of Transportation of the Texas & Pacific Ry., has been promoted to be Superintendent of the Rio Grande division, with headquarters at Big Spring, Tex.

Mr. A. S. Lowrie, for many years Chief Engineer of the Montgomery Light & Water Co., Montgomery, Ala., has been appointed Superintendent of the municipal water and electric plant at Dothan, Ala.

Mr. Robert R. Crowell, who was dismissed as head of the Topographical Bureau of the Borough of Queens, New York City, in 1912, has been reinstated by a decision of the Court of Appeals of New York State.

Mr. David T. Day, M. Am. Inst. M. E., Petroleum Expert of the United States Geological Survey, has resigned to engage in private practice. He is succeeded by Mr. John D. Northrop, Geologist, of the U. S. Geological Survey.

Mr. William A. Mitchell has resigned as Director and Treasurer of A. L. Guidone & Co., Inc., General Contractors, to engage in general contracting under his own name, at 2409 Walton Ave., the Bronx, New York City.

Mr. Joseph Billingham, former General Inspector of the American Locomotive Co., Schenectady, N. Y., has been appointed Superintendent of Motive Power of the Grand Trunk Pacific Ry., with headquarters at Transcona, Man.

Mr. Victor T. Noonan, recently Secretary of the general safety committee of the Rochester (N. Y.) Railway & Light Co., has been appointed Director of Industrial and Public Safety of the State of Ohio, a newly created office.

Lieut.-Col. Chester Harding, M. Am. Soc. C. E., Corps of Engineers, U. S. A., recently Engineer Commissioner of the District of Columbia, has been transferred to the Panama Canal, where he becomes Engineer of Maintenance, succeeding Col. H. F. Hodges.

Mr. B. F. Thomas, M. Am. Soc. C. E., U. S. Assistant Engineer, recently in charge of Kentucky River improvements with headquarters at Frankfort, Ky., has been transferred to his old office at Cincinnati, Ohio, as Principal Assistant Engineer of the Cincinnati District, No. 2, Corps of Engineers, U. S. A.

Messrs. E. Darrow, formerly Manager of the Merchants' Heat & Light Co., and R. M. Cass, formerly Electrical Engineer of the Indianapolis Light & Heat Co., have formed the Indianapolis Engineering Co., with offices in Indianapolis, for engineering, appraisal and operating work in connection with public utilities.

Messrs. Frank A. Randall, Assoc. M. Soc. C. E., formerly Chief Engineer of Morey Newgard & Co., Chicago, Ill., and William H. Warner, formerly with D. H. Burnham & Co., have formed a partnership under the firm name of Randall & Warner, Civil and Structural Engineers, with offices at 511 Rector Bldg., Chicago.

Capt. George E. Burd, U. S. N., Engineer Officer, U. S. Navy Yard, New York City, has been appointed Industrial Manager of the Yard under a new system of organization. The Commandant of the Yard will hereafter devote his whole time to military administration, while the work construction and repair will be under Capt. Burd.

Mr. Wm. D. Kerr has resigned as Director of the Bureau of Public Service Economics and has become a member of the firm of Kerr & Kerr, Attorneys, of Chicago. Mr. Kerr has also been appointed to a lectureship in the School of Commerce of Northwestern University dealing with the subject of Transportation Economics and Law.

Messrs. W. H. Ellison and V. B. Stanbery, both of whom were recently employed by the California State Engineering Department and in the structural engineering department of the Panama-Pacific exposition, have formed a partnership under the firm name of Ellison & Stanbery, Structural Engineers, with offices at 251 Kearny St., San Francisco, Calif.

Mr. Lucien S. Johnson, M. Am. Soc. C. E., U. S. Assistant Engineer, in charge of the Big Sandy River improvement, with headquarters at Louisa, Ky., has been appointed Assistant Engineer in charge of the Kentucky River improvement, with headquarters at Frankfort, Ky., succeeding Mr. B. F. Thomas, transferred, as noted elsewhere in these columns.

Mr. C. E. Coolidge, recently Mechanical Engineer of the Denver & Rio Grande R.R., of Salt Lake City, Utah, has been appointed Associate Professor of mechanical engineering at the University of Idaho, Moscow, Idaho. Prof. Coolidge temporarily succeeds Prof. G. L. Larson, who has been granted leave of absence for a year, to take up research work at the University of Wisconsin.

Mr. Charles G. Elliott, M. Am. Soc. C. E., for many years Chief of the Drainage Investigations, United States Department of Agriculture, recently Consulting Engineer, Washington, D. C., has been appointed Chief Engineer of the Peace Creek drainage district, Bartow, Fla. Mr. Elliott has been Consulting Engineer of the project since early in the year. This is one of the largest drainage projects in Florida, comprising about 46,000 acres.

Mr. Henry H. Westinghouse, M. Am. Soc. M. E., formerly Vice-President, has been elected President of the Westinghouse Air Brake Co., of Pittsburgh, Penn., to succeed his brother, the late George Westinghouse. Mr. Henry Westinghouse has been associated with the company for over 40 years, having been General Agent, General Manager and Vice-President. He was one of the founders of Westinghouse, Church, Kerr & Co., and for several years was identified with its management.

Mr. Arthur F. Barnes, M. Am. Soc. M. E., formerly at the head of the Engineering School of Middlebury College, Vermont, has been appointed Dean of Engineering at the New Mexico College of Agriculture and Mechanical Arts, which has recently been reorganized. The school embraces the departments of mechanical, electrical, civil and irrigation engineering. A new engineering building was completed in 1913 and the shops almost entirely reëquipped with modern machinery and tools. Courses of study are being revised and a new and complete course in irrigation engineering will be made a specialty of the school.

Maj. Charles W. Kutz, M. Am. Soc. C. E., Corps of Engineers, U. S. A., recently in charge of works for the defense of Washington, D. C., and of river and harbor improvement work in the Washington district, has been appointed Engineer Commissioner of the District of Columbia, to succeed Lieut.-Col. Chester Harding, transferred, as noted elsewhere in these columns. Maj. Kutz graduated from the United States Military Academy at West Point in 1893. He has been a member of the board of consulting engineers of the United States Reclamation Service, and from 1911 to 1913 he was Chief Engineer of Philippine division of the Corps of Engineers.

Mr. Thomas J. Kennedy, former President of the Superior Construction Co., Ltd., at Sudbury, Ont., has been elected President of the Algoma Central & Hudson Bay Ry. and the Algoma Eastern Ry., with headquarters at Sault Ste. Marie, Ont. Mr. Kennedy began his railway experience with the engineer corps of the Canadian Pacific Ry. in 1874. Later he was Engineer for a contracting firm for the construction of the same railway. In 1885 he entered the operating department of the Canadian Pacific Ry. as Roadmaster and was soon promoted to be Division Superintendent. Later he was General Superintendent and Traffic Manager of the Algoma Central & Hudson Bay Ry., of which he is now elected President.

Mr. George S. Rice, M. Am. Soc. C. E., Consulting Engineer, of New York City, and former Chief Engineer of the old Rapid Transit Commission, which built the first New York City subways, has been appointed Division Engineer of the Public Service Commission to succeed Mr. Frederick C. Noble, M. Am. Soc. C. E., whose resignation was noted in our personal columns of Sept. 17. Mr. Rice was born in Boston, Mass., Feb. 28, 1849, and graduated from Harvard University in 1870. For two years he was Assistant Engineer of the Lowell (Mass.), water-works and of the Boston water-works. For the five years, 1872-'77, he was Division Engineer for the additional water-supply of Boston, and for a year was Assistant Engineer in direct charge of the main drainage works of the city. He then succumbed to the mining fever which followed the great silver discoveries in Colorado, and along with many other young engineers went West, where for several years he was a Mining Engineer in Arizona and Colorado. He returned East in 1887 to become Principal Assistant Engineer of the main drainage works of Boston. The same year he was appointed Deputy Chief Engineer of the New Croton Aqueduct, New York City. In 1891 he returned to Boston as Chief Engineer of the Boston Rapid Transit Com-

OBITUARY

[illegible] Manager of Sales of the [illegible] Manufacturing Co. [illegible], died Oct. 20, at his home [illegible]

[illegible] of the firm of Steel & [illegible], [illegible] Jersey City, N. J., died at the Roosevelt Hospital, New York City, Oct. [illegible]. He was born at Morristown, N. J., in [illegible].

[illegible] for many years a Superintendent of Construction for [illegible] and the George A. Fuller Co., [illegible], died at his home in Boston, Mass., Oct. [illegible]. He was born in Maine in 1864.

[illegible] General Manager of the North[illegible], died Oct. 3, at his home in St. Paul, Minn., aged [illegible] years. His railway experience was begun in [illegible] as a messenger boy with the Chicago, Burlington & Quincy R.R. He was at one time General Superintendent of the Chicago Great Western R.R. at St. Paul, Minn. He joined the operating staff of the Northern [illegible] Ry. in 1897 as General Superintendent of the Central [illegible].

Daniel A. T[illegible], President of the D. A. T[illegible] Co., Charlotte, N. C., Engineers and Contractors, died Oct. 1[illegible]. He was born in South Carolina in [illegible]. He was educated at South Carolina College and the Rensselaer Polytechnic Institute, where he graduated in [illegible]. Leaving college he entered the [illegible] steel works of John A. Griswold & Co., Troy, N. Y., and [illegible] was with the Bethlehem Iron Works, Bethlehem, Penn., under the late John Fritz. [illegible] he went into the [illegible] manufacturing business at [illegible]. [illegible] he established a business in Charlotte, N. C., as a Contracting Engineer, and as such [illegible] constructed [illegible] manufacturing plants. He was the author of several books on the cotton industry.

[illegible]

and to have laid out and supervised the construction of the [illegible] around the base of the shaft. He supervised the construction of many other [illegible], the most notable of which was the [illegible] Library of Congress. Under the direction of Gen. Casey, Mr. Green organized the office and construction work so [illegible] that the building was [illegible] completed well within the appropriation. Mr. Green also had charge of construction of the Washington Public Library building and was consulted on the construction of [illegible]. He not only was Superintendent of Construction but suggested [illegible] changes in designs and plans which were of great importance. Moreover he was an inventor of library fittings and devices, including the book stacks and carrying system of the Library of Congress as well as special racks for maps and newspapers. He was a member of many scientific and [illegible] societies and was a prominent and useful member of the American Unitarian Association. He is survived by four children, one of whom is Bernard Lincoln Green, M. Am. Soc. C. E., Vice-President of the [illegible] Engineering Co., Cleveland, Ohio. The following tribute was paid to the long, honest and honorable service of Mr. Green on Mar. [illegible], on the completion of his 50 years of service for the government:

On this day you will have completed fifty years of service to the United States. To few, indeed, has such a term been vouchsafed, and, while the individual qualities which have characterized your own relation with the government are happily not unique in its history, few men, indeed, can show a record which combines qualities so [illegible] complete of inventive skill, technical knowledge, executive energy, simplicity in method, [illegible], persistent and unselfish devotion, [illegible] integrity and a modesty more than [illegible].

The permanent memorials of these qualities are in stone and [illegible]. They are in structures of beauty, of dignity and of efficiency, with which your name will forever be associated. But the friends and [illegible] of the public service whose names are signed below, [illegible] in which scores of others would have been glad to [illegible], desire to offer you their acknowledgments, their congratulations and their warmest wishes, [illegible] of the day which [illegible] help to [illegible] such leisure hours as you may allow yourself hereafter.

VOLUME 72 NOVEMBER 5, 1914 NUMBER 19

Ashokan Reservoir Roads, Built by the New York City Board of Water Supply

To replace many miles of country highways wiped out by the Ashokan Reservoir of the Catskill Water Supply of the City of New York, the city agreed to substitute about 30 miles of new highways "equal in every respect to those constructed by the State of New York in the County of Ulster." The agreement was in recognition of the inconvenience caused by having but one means of crossing the reservoir in its whole length of 12 miles.

It was further agreed that the city would undertake to maintain these roads forever. The Board of Water Supply engineers decided to pave these roads with vitrified brick, and bids were obtained from ten bidders rang-

Constructing a Bituminous Macadam Pavement; Ashokan Reservoir Roads

[illegible] from $1,701,1[illegible] to $1,6[illegible]. The aver[illegible] are shown in Table I.

TABLE I. AVERAGE BID FOR BRICK PAVEMENT

Item	Description	Unit	Quantity	Average
1	[illegible]	[illegible]	[illegible],000	$0.319
2	[illegible]	Cu.yd.	[illegible]	[illegible]
3	[illegible]	Cu.yd.	1,000	[illegible]
4	[illegible]	Cu.yd.	[illegible]	[illegible]
5	[illegible]	Cu.yd.	[illegible]	[illegible]
6	[illegible]	Cu.yd.	[illegible]	[illegible]
7	[illegible]	Cu.yd.	[illegible]	7.60
8	[illegible]	Bbl.	[illegible],000	1.90
9	[illegible]	Sq.yd.	[illegible],000	2.22
10	[illegible]	Cu.yd.	[illegible]	2.9[illegible]
11	[illegible]	Lin.ft.	[illegible]	0.402
12	[illegible]	Sq.ft.	1,500	0.347
13	Timber and lumber	M ft. B.M.	[illegible]	[illegible]
14	[illegible]	Post	40	10.72
15	[illegible]	Pound	10,000	0.0[illegible]
16	[illegible]	Lin.ft.	70,000	0.1[illegible]
17	[illegible]	Lin.ft.	100,000	0.028

The Board of Estimate and Apportionment was unwilling to make such a large original outlay and the decision of the type of paving was referred to a committee comprising the Chief Engineer of the Board of Estimate and Apportionment, the Chief Engineer of the Department of Finance and the Consulting Engineers of the five boroughs of the city. This committee recommended "pavement of a bituminous character," and the Board of Water Supply engineers proceeded to write specifications and obtain bids for a very high class of bituminous macadam, or perhaps more properly asphaltic-concrete pavement.

The contract for about 30 miles of this pavement and about [illegible] miles of waterbound macadam road was let in one job to the State Highway Construction Co., of New York City, the lowest bidder, for $659,080, probably one of the largest contracts for road construction ever let. Bids ranged from this figure to $716,115. Table II shows a tabulation of the successful bid and of the average bid.

TABLE II. BIDS FOR BITUMINOUS PAVEMENT

Item	Description	Unit	Quantity	Successful bid	Average
1	[illegible]	[illegible]	180,000	$0.35	$0.4[illegible]
2	[illegible]	Cu.yd.	45,000	0.54	0.5[illegible]
3	[illegible]	Cu.yd.	1,000	1.97	2.1[illegible]
4	[illegible]	Cu.yd.	[illegible]	2.10	1.94
5	[illegible]	Cu.yd.	[illegible]	[illegible]	[illegible]

9	[illegible]	Bbl.	1,[illegible]	[illegible]	[illegible]
10	[illegible]	Cu.yd.	[illegible]	[illegible]	[illegible]
11	[illegible]	Lin.ft.	[illegible]	[illegible]	[illegible]
12	[illegible]	Sq.ft.	1,500	[illegible]	[illegible]
13	Timber and lumber	M ft. B.M.	[illegible]	[illegible]	[illegible]
14	[illegible]	[illegible]	[illegible]	12.[illegible]	13.[illegible]
15	[illegible]	Pound	[illegible]	[illegible]	[illegible]
16	[illegible]	Lin.ft.	[illegible]	[illegible]	[illegible]
17	[illegible]	Lin.ft.	[illegible]	[illegible]	[illegible]
18	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
19	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

The contract was awarded July [illegible], 191[illegible], and work has progressed steadily during seasonable weather to date.

The [illegible] part of the road surface is a well constructed water-bound macadam, with rolled foundation [illegible] 6 in. deep. The bottom course is [illegible] in. of stone [illegible] in. in size, placed in two [illegible] layers, rolled and filled with screenings. Before the bituminous top was placed, the bottom course was [illegible] so that the large stones were exposed and spaces between the stones from $\frac{1}{8}$ in. to $\frac{1}{4}$ in. deep created. This was done to give the bituminous coat a proper bond and to prevent its creeping.

The bituminous coating itself is a 2-in. course of $\frac{1}{2}$-in. to 1½-in. stone mixed with 5 to 7% asphaltic cement. A description of the construction plant and an abstract of the specifications may be found in ENGINEERING NEWS, of Aug. 6, 1914, p. 300.

A Graphic Method of Determining Runoff in Storm Sewers

By O. HUFFLAND*

Among the problems of municipal engineering, none perhaps is today more obscured in the fog of theories than that of sewer design. The subject is a difficult one, and the data at hand on which to base conclusions are meager, so that it is hard to disprove theories that are obviously faulty by direct tangible demonstration of their weakness. But its study has now extended over more than 50 years, and has reached a stage where, in the hands of capable men, it has developed into a true science, so that the continuation of old errors is no longer excusable. That such errors are continued can be attributed to but two reasons: one, ignorance of this progress, and the other lack of courage to admit old errors. Both are unfortunate for the client of the engineer laboring under these shortcomings.

In the scientific periodicals and the publications of our engineering societies, many papers and the resultant discussions have been printed during the last 10 years in which all mention of this progress is omitted; and the old, concededly weak formulas, with assumed factors, startling reciprocals and fractional exponents, have become the shuttlecock between writers of a little book learning and a conspicuous lack of experience. "Capillary action for small depths," "the inertia of the water" on the surface, "wetted film" are illustrative expressions, instead of a plain statement that the delay in runoff is due to unevenness of surface, and a primary absorption and evaporation at the beginning of a storm. Add to the preceding a "cubic parabola" and you have the mystery complete.

These methods have been discarded in other countries, where for at least a half dozen years much simpler and more correct methods have been exclusively used by the best engineers without, so far as I know, getting into print here.

The new method discards many of the fetishes of the old school, and compels the engineer who uses it to have some practical knowledge of the subject, instead of reading his "computations" from a ready-made diagram prepared under some other man's theory, which very rarely fits the conditions which the new work is intended for.

A brief history of the new way may help to give it standing. As early as 1887 an Italian engineer in studies for the sewers of Milan pointed out the inadequacies of the old methods. In 1891, Prof. Frühling, one of the most eminent authorities on sewerage, pointed out the absurdities of the exponential formula for determining the correct quantity of water flowing through sewers

*Asst. Engr. Consulting Engineer's office, Borough Manhattan, Municipal Building, New York City.

as the result of a given rainstorm. Between that date and the present time the following have added their approval of the opinions above expressed, and have provided a new graphic method exquisitely simple and elastic enough to adjust itself to any combination of conditions for which sewer sizes must be found: Knauff, 1891, 1896, 1911; Forbat-Fisher, 1901; Hecker, 1910; Schulze, 1902; Frühling, 1904; Heyd, 1905; Kayser, 1905; Vicari, 1907, 1908, 1911; Bange, 1908, 1912; Nehring, 1908; Weyrauch, 1912; Kalbfuss, 1912; in fact, practically all the European writers of this period with one exception, and that is F. Grimm, in the Gesundheits Ingenieur, 1914, who makes a plea for the old methods by saying that five smaller cities have used them in the past and have not yet had trouble, but does not deny that the new methods are better.

One of the underlying distinctions of the new method is an acceptance of the postulate "that a definite intensity of rainfall during a definite period must result in a definite maximum of runoff, but that this maximum does not necessarily occur when the runoff from the whole drainage area reaches a given point in a collecting sewer." A "definite intensity" means, of course, a rate of precipitation which is substantially uniform during the "period," and not an accumulation of rainfall at various intensities during an assumed period. Uniform intensities of 1 in. per hr. and over rarely have a duration exceeding 20 minutes in the neighborhood of New York.

In a sewer system for an area in which the period of maximum intensity of rainfall is less than the time required for the maximum runoff to reach the outlet, the use of a constant formula "is wrong, gives senseless results and is not justifiable, simply because certain systems built upon such computations have not yet failed." (Prof. Weyrauch.)

To say that the eight or ten best known formulas are based on error may seem presumptuous; but the application of a constant to "area" instead of "time" seems to justify such a statement. Mr. Kuichling's is the only departure from such a theory, and for this and the insistence on the use of the actual uniform intensities of rainfall, instead of misleading accumulated quantities over long periods, he deserves the credit not only for correct analysis, but for his courage in dissenting from an old and universally accepted error.

The authors mentioned above describe a number of methods, but the one that has found most favor is a modified form of that given by Vicari and printed in the 1909 and 1912 editions of "Hütte," Vol. III, the well known German engineering handbook, from which I will make a free translation of the essential portions, retaining the metrical units, which can easily be transformed into terms current here.

Vicari's Method of Computing Runoff

If q_r equals the quantity of water in liters per second falling on a hectare, and E equals the number of hectares in the area under consideration, then the total runoff in liters per second, Q_r, is not $q_r E$, but $Q_r = \varphi q_r E$. In this, φ is the percentage of rainfall that is not evaporated or absorbed, and usually is called the coefficient of imperviousness.

The following values may be taken for φ for different surfaces:

Roof surfaces	0.8 to 0.9
Waterproof pavement	0.7 to 0.9
Common pavement	0.4 to 0.7
Macadam pavement	0.4 to 0.6
Park walks	0.2 to 0.4
Unpaved surface	0.1 to 0.2
Parks and gardens	0.0 to 0.1

As a drainage area generally consists of an aggregation of smaller areas of different degrees of imperviousness, the coefficient for the total district would be

$$\varphi = \varphi_1 p_1 + \varphi_2 p_2 + \varphi_3 p_3 + \ldots$$

in which p_1, p_2, p_3, etc., are fractions of the area having a different surface, and therefore a different coefficient φ_1, φ_2, φ_3, *etc.*

Water Reaching Sewer—At the beginning of a rain storm, only that area nearest a given point in a sewer furnishes water to it. As the storm continues, the areas farther away gradually contribute until, if the storm lasts long enough, water from the entire district will reach the given point. From this it appears that the duration as well as the rate of rainfall affects the discharge of a sewer. If it stops raining before water from the remotest part of the district drained reaches the part of the sewer under consideration, then only a fraction of the total runoff in liters per second, $Q_r = \varphi q_r E$, will be carried by the sewer at this point. This fraction was designated by a uniform retardization coefficient by Bürkli-Zeigler, Mank, Brix, Büsing and others; but this method has justly been discarded by Frühling because it failed to regard the size and shape of the area drained, as well as the velocity of flow in the sewers computed.

Method of Computing Runoff—The delayed runoff from the outer areas causes a reduction in the discharge at any point in a sewer, which may be determined by making a flow diagram for that point.

This diagram is developed by plotting the duration of rainfall as asbscissas and the resulting amount of runoff as ordinates of a right-angle system of coördinates.

Flow Diagram—Such a diagram is shown in Fig. 1 and may be obtained as follows: Assuming the distance from the remotest portion of a sewer district to a point in the sewer to be l and the velocity of runoff in the sewer to be v (this assumes that the sewer drains the remote part), then the time, t_l, that it will take water falling at the edge of the district to reach this point will be

$$t_l = \frac{l}{v}$$

At the end of this time, the entire drainage area E_l hectares is supplying the total discharge $Q_l = \varphi q_r E$, liters per sec., providing the storm continues.

In the diagram shown, the point B is located by taking t_l as the abscissa and Q_l as the ordinate. To obtain Q_l, it is necessary to find the rainfall in liters per sec. per hectare, q_r, for the storm for which the system is to be designed. This value of q_r multiplied by the number of hectares E_l and this result multiplied by the coefficient of imperviousness for the area considered gives Q_l.

Under the admissable assumption that the runoff to the sewers is uniform from each contributing strip and that t_r indicates the duration of the storm considered, the runoff Q_t at any time t is represented by the ordinate to the lines A,B,D,C.

It is evident from the diagram that when t (any time

of which the runoff is desired) is less than t_e, the time required for water falling at the edge of the district to reach the sewer junction, that the amount of water flowing in the sewer is only a portion of the quantity which will be flowing at the end of the time t_e. This ratio may be expressed as follows:

$$Q_t = \frac{t}{t_e} Q$$

in which Q_t equals the runoff in liters per sec. at the time t.

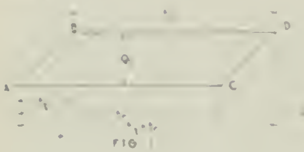

FIG 1

FIG 2

FIG 3

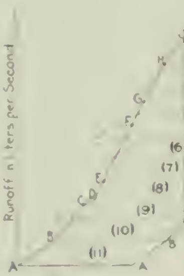

FIG 4

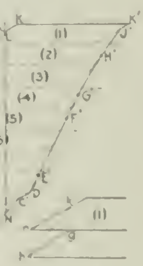

FIG 5

If t is greater than t_e and less than t_r, then $Q_t = Q$. If t is greater than t_r but less than $t_r + t_e$, then

$$Q_t = \frac{t_e + t_r - t}{t_e} Q$$

and, if t is greater than $t_e + t_r$, then $Q_t = 0$.

It takes the same time, t_e, for water falling at the remote portion of the district, at the beginning of the storm, to reach the junctions in question as it does for water falling at the end of the storm to reach this point; therefore, since the duration of the storm, t_r, is a constant and t_e influences the discharge at the beginning and end of the storm by the same amount, AB and CD are parallel.

SUMMARY OF PROCEDURE—In order to make the foregoing nomenclature and results more clear for practical use, they may be summarized as follows:

q = Quantity of water in liters per sec. falling on one hectare.
F = Number of hectares in area considered.
ψ = Coefficient of imperviousness.
Q_t = Quantity of water in liters per sec. running off from F hectares.
l = Length of stretch of area considered.
v = Velocity of flow in sewer.
$t_e = \frac{l}{v}$ = Time required for water falling on remote part of drainage area to reach sewer junction.
t_r = Duration of rainfall.

METHOD OF COMBINING FLOW DIAGRAMS—The preceding has shown how the flow diagram for a single area drained by a lateral is obtained. For a system of drainage areas, the flow diagrams for the individual areas are combined according to the following rules:

1. The flow diagrams for areas which discharge to the same sewer junction have the same initial abscissa.

2. The flow diagram for the area between two junctions has an origin of abscissa to the left of the diagram above it by a distance

$$t_e = \frac{l}{v}$$

where l is the length of the drainage area and v is velocity in the sewer draining that length.

3. In plotting the diagrams, begin with the area at the extreme edge of the district and continue downward step by step.

GENERAL CASE—The foregoing may be made more clear by considering a general case. The combined diagrams for the system of laterals shown in Fig. 2 are shown in Fig. 3 and obtained as follows.

In Fig. 3 (1) represents the flow diagram for the area drained by l_1, Fig. 2; t_1 is the time required for water falling at a to reach I; Q_1 is the total runoff in liters per second from the area drained by l_1, all of which does not reach I until the end of time t_1. Q_1 will be the amount of discharge for which the lateral l_1 must be designed. (2) represents the flow diagram for l_2, Fig. 2, and since l_1 and l_2 flow into the same junction I, they have the same initial abscissa. t_2 is the time required for water falling at b to reach I and

$$t_2 = \frac{l_2}{v_2}$$

Q_2 is the total runoff in liters per sec. from the area drained by l_2, and the quantity reaches I at the end of the time t_2. The total quantity of water per sec. reaching I at the end of any time t is the sum of the ordinates of the diagrams (1) and (2) at the end of that time, t being measured to the right from h.

For (3), the time t_3 is laid off to the left of the origin of (1) and (2) as the area drained by l_3 lies between junctions I and II. t_3 is the time required for water falling at I to reach II.

$$t_3 = \frac{l_3}{v_3}$$

and it will be at the end of this time that water from l_1 and l_2 reaches II. Q_3 is the total runoff from the area drained by l_3. To find the quantity of water in liters per sec. flowing in l_3 at II at any time t, with O as an origin and t as abscissa, sum up the ordinates at the end of time t of all the preceding diagrams. In this case, the maximum amount of discharge that l_3 would be designed for, would be $Q_1 + Q_2 + Q_3$. The diagram is continued in a similar manner for the remainder of the system.

The sum of the abscissas $t_1 + t_3 + t_5 + t_8 + t_{11}$ is the total time required for water falling at a to reach VI. These correspond to l_1, l_3, l_5, l_8 and l_{11}, Fig. 2, which form the main sewer. The laterals l_2, l_4, l_6, l_7, l_9 and l_{10}

discharging into it do not affect this time, but do add to the quantity, as shown by the ordinates in the diagram.

The sum of these ordinates indicates the total quantity in liters per second that flows through the sewers at any required time. For instance, the amount of water passing through the collecting point VI in the time t_n (see Fig. 3) consists of the sum of the ordinates at the end of this time for all the preceding diagrams ($Q_{11} + Q_{10} + Q_9 + Q_8 +$ a portion of Q_7, Q_6 and Q_5, while (1), (2), (3) and (4) furnish no water at this time. For the time t_m laterals l_8 to l_1 furnish water to VI, the quantities from l_{11}, l_{10} and l_9 having already passed VI.

Maximum Discharge—The maximum quantity of water flowing through VI is indicated by the longest ordinate in the combined diagram, Fig. 3, the location of this ordinate also showing the time at which this occurs; or, in other words, the maximum quantity of water that is discharged at VI (and which l_{11} should be designed to carry) would be at the end of the time where the sum of the ordinates of the diagrams (11) to (1) is a maximum.

Method of Revising Combined Diagram—In order to simplify the finding of the required ordinates, a method of adjusting the combined diagram has been devised, shown in Fig. 4. It consists in turning down the projecting ends of the single diagrams on the left and turning up those on the right into a compact figure from which the ordinates may be easily scaled. This is accomplished as follows: The area (1), Fig. 5, protrudes to the left of (2) by an amount nkg. Draw the line hk in such a manner that its vertical distance from hg at any point is equal to the distance of nk above ng at the same vertical; hk is therefore a part of the corrected diagram. By locating points as above, the line $ABCD$, etc., is found, and by a similar method $A'B'C'D'$, etc., may be obtained. Since t_r is constant $A'B'C'D'$, etc., will be parallel to $ABCD$, etc. It would therefore be only necessary to plot and correct one of the ends of the diagram; and by moving the line so found horizontally for the distance t_r, representing the time of the storm under consideration, the diagram may be completed.

Any ordinate of the continuous diagram, Fig. 4, will equal the sum of the ordinates of the individual diagrams, Fig. 3, at the same vertical. The longest ordinate within the diagram, Fig. 4, is at LN, which will be the quantity of water in liters per second for which the outlet l_{11} at VI must be designed. Lateral l_9 would also carry the same amount.

The quantities of storm water for which the system would be designed are therefore as follows:

Lateral	Quantity of water in liters per sec.
l_1	Q_1
l_2	Q_2
l_3	$Q_1 + Q_2 + Q_3$
l_4	Q_4
l_5	$Q_1 + Q_2 + Q_3 + Q_4 + Q_5$
l_6	Q_6
l_7	Q_7
l_8	$Q_6 + Q_7 + Q_8$
l_9	LN
l_{10}	Q_{10}
l_{11}	LN

Caution and Final Comment

In order to avoid misunderstanding, the present author would point out that the method above described permits the use of any formula for fixing the percentage of water that reaches the sewers, as well as any formula for determining the velocity of flow in them. It is sufficiently elastic to fit any condition, and will permit the engineer to make use of information furnished by a study of the area to be drained.

But its most striking advantage is the clear demonstration that the application of a constant to the "area" is wrong in principle. By most of the old methods the total area drained by all the sewers, l_1 to l_{11}, would have been used as a base of computation, resulting theoretically in a sewer gradually increasing in the size to the outlet. The new method conclusively shows that such a theory is faulty, and that l_{11} carries no more water at any time than l_9, notwithstanding the increased area drained by l_{10} and l_{11}, the flow from the latter having passed out before the maximum from the whole area reaches the outlet.

The Illuminating Power of Kerosene Oil is reported on by William Kunerth, Assistant Professor of Physics and Illuminating Engineering, Iowa State College of Agriculture, in a bulletin of the Iowa Engineering Experiment Station. The tests were to determine the quality of kerosene oil used in the state and relations between the illuminating power and physical properties, so that the usefulness of an oil could be judged without the long, tedious tests of burning. Some 61 samples in all were tried.

The oils were burned in a small metal lamp with a No. 2 flat-wick burner and glass chimney. The wicks were all of the same weight and ⅞ in. wide. About one-half pint of oil was used in each test to keep temperature effects similar. Before testing a sample, a new wick was burned in it for three hours to reproduce service conditions. A new wick was used for every sample of oil. The amount of oil burned was determined by balance and stop watch. Candlepower was measured on a 2-in. photometer. Several determinations were made with flame at different heights and the curve of candlepower and illuminating power plotted. Because of great influence of atmospheric conditions, it was necessary to test a sample of one oil selected as standard whenever unknown specimens were tested. The term "illuminating power" used below is used to cover the number of candlepower-hours per gallon of oil.

A greater flux of light was obtained from the cheaper oils, the average cost of 100 candlepower-hours running from 0.89c. for a 10c. oil to $1.97 for a 27c. oil. Higher-priced oils were from Eastern fields and had a lesser density. The heavier oils fogged the chimney more and the lighter oils less, the low illuminating power of the latter being somewhat compensated for by lessening the labor or expense of cleaning. Oils of lowest illuminating power charred the wicks most. No difference in the unpleasantness and quantity of odor given out by the different oils could be detected Contrary to the usual statements, the lighter oils are not as desirable as the heavier ones. The average density of oils whose illuminating power was less than 1100 cp.-hr. per gal. was 0.801 gram per c.c., while the average density of oils with an illuminating power above that figure was 0.818 gram. The oils of greater density also had a greater relative carbon content. All the oils had a flash point above 100° F. The oils having high illuminating power also had a high flash point, and vice versa, those below 1100 cp.-hr. showing 110° average, while those above had 116° average. The relation between illuminating power and burning point was similar, but not as well marked. A range of over 50% was found in viscosity of the samples and the relation of viscosity to illuminating power was not very definite, although in general it appeared that the oils of high illuminating power were comparatively the more viscous. An increase in surface tension was in general accompanied by an increase in illuminating power. Seven of the samples selected had been colored red and were light oils with low illuminating power. Therefore, one of the heavier oils was colored with alkanet root, whereupon its illuminating power was decreased 2%. A sample exposed to daylight and sunlight for six weeks showed a decrease of 15% in illuminating power.

The cost of kerosene illumination from the average of the samples tested was found to be 19c. per 1000 cp.-hr. This was found to be the same as the cost of electric illumination with tungsten lamps in Ames, the lamps having an efficiency of 1.25 watts per candlepower and current selling at 11.7c. per kw.-hr.

Development of Sand and Gravel Deposits

By W. H. Wilms*

SYNOPSIS—The preliminary steps in developing sand and gravel deposits are discussed in detail. The type of steam-shovel, the essential points in stripping overburden by hydraulicking, the layout, grades and construction features of railway tracks are described from the point of view of one having several years' experience in this work. Other articles will follow, describing and discussing methods of operating sand and gravel plants.

With the remarkable growth of the sand and gravel industry during the past five years has come an increased demand for a better grade of material. New standards of quality have been set up which the producer must be prepared to meet if he is to continue in business. For some plants now operating this means better preparation of material; for others it means the abandonment of the inferior deposits now being worked; for no amount of preparation will ever make a first-class product from poor and defective material.

The next five years will undoubtedly witness another large increase in the growth of this industry. New deposits will be opened up, new plants put into operation and many now engaged in other lines of industry will turn toward this. Mistakes, of course, will be made, for the industry is beset with all manner of snares and pitfalls for the inexperienced.

With the idea of giving an outline of the essential requirements in the development of sand and gravel deposits and the present methods of design and operation of screening and washing plants this and a subsequent paper have been prepared. To engineers interested in [illegible] the writer hopes they will prove of special interest and value.

[illegible] of Deposit

[illegible] cannot be laid upon the importance of a thorough examination and test of a deposit under consideration for development. Only too often a hasty and superficial examination is the rule and not the exception.

Test Wells—Due to extreme variations in the character of sand-gravel within comparatively short distances, a sufficient number of test wells should be sunk to make [illegible] the nature and character of the deposit. [illegible]

[illegible]

[illegible]

measured on all four sides of the well. The dip or angle of inclination of each stratum should also be noted. The elevation of the bottom of each stratum referred to a common datum should also be obtained with a view to connecting it, if possible, with similar strata in the other wells.

Analysis of Material—The size and gradation of the material in each stratum should be obtained by taking the entire amount excavated and screening it through a series of sieves. The character or composition of this material should also be obtained, i.e., the percentage of crystalline, granular, slaty and compact rocks and their hardness. The amount and character of the impurities should also be ascertained. The composition, average size and percentage by weight of all stone over 2 in. should also be obtained; this will afford a criterion as to the amount of crushing necessary.

Quantity—The elevation of the bottom of the deposit in each test well should be obtained and referred to a common datum. By connecting up these elevations a comparatively accurate profile can be made of the bottom of the entire deposit—very useful information if it is finally decided that the deposit is worth developing.

Development of Deposit

Considerations of capacity, depth of deposit, presence of water, etc., largely determine, of course, the method of excavation. Where conditions, however, will permit of the development and working with a steam-shovel, this method of excavation has many advantages worthy of consideration. It often happens that where dry deposits have been opened up and worked over with an orange-peel, clam-shell, or drag-line bucket, or any excavator of this class, the pit is left in very bad condition when increased capacity demands a change to steam-shovel operation.

Often steep grades out of the pit and other conditions make the change to steam-shovel operation under the above conditions an expensive proposition, if not absolutely prohibitive. The possibility of a possible future increase in capacity and a change to steam-shovel operation should be kept in mind in considering the type of machine for original development.

Steam-Shovel Development—In considering development with a steam-shovel, where a working face or bank has to be opened up, two methods of attack are possible. The working face may be obtained by the [illegible] method or by a through cut. By the former method the face is obtained by taking a series of [illegible] [illegible]

[illegible]

*[illegible]

side cutting is the necessity of using a shovel that can dig at least from 5 to 8 ft. below the loading track. This means either an A-frame or railroad shovel with an operating crew of three men, or an excessive and impracticable amount of blocking for a revolving shovel.

Unless the deposit presents a natural face or bank from which to begin operations it is generally advisable to make a through cut. In so doing the full working face is quickly attained, assuring a uniform run of material and a low initial stripping charge per cubic yard of material.

Of course there are some disadvantages attending the use of this method of attack such as cramped quarters, the "spotting" of but one car at a time to the shovel, with consequent reduction in the capacity of the machine; but the advantages generally far outweigh the disadvantages.

Type of Steam-Shovel—The type of shovel to use largely depends, of course, upon the capacity required. Where the requirements of capacity come within the limits of a revolving, one-man shovel, however, there is no question but what this is the type of shovel to use. There are many such shovels operating in gravel pits excavating from 300 to as high as 900 cu.yd. of material per 10-hr. day, with an operating crew of one man; and this man does his own firing.

In operating an A-frame or railroad shovel it is necessary, of course, to bring the shovel back to the beginning for each successive cut. Unless a track is kept built up behind the shovel a delay of several days is necessary to "cut out" the shovel, bring it back, shift the running track and "cut in" again. Often this delay must be suffered at the busiest time of the season. Delays to a busy plant are costly and anything that will reduce them is certainly worth consideration.

Stripping Deposits

The problem of the removal of the overburden or stripping should be studied in conjunction with development; for upon the solution of one largely depends the solution of the other. The subject is a large one and demands more space than can be allotted here for even a brief analysis.

Hydraulicking—I will, therefore, confine my remarks to a method of stripping that has been found to be the most effective and economical where the conditions are favorable for it. This is removal or stripping by water or hydraulicking. It has been my experience, that where conditions permit of this method, it is accomplished at a cost far below that of any other. I have removed many hundreds of cubic yards of stripping by hydraulicking for as low as 6c. per cu.yd.

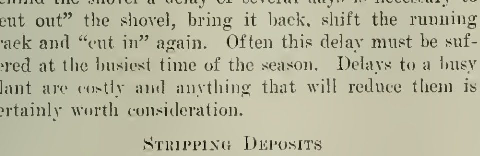

Fig. 1. Sketch of Layout for Hydraulic Stripping

The conditions necessary for hydraulicking are a plentiful supply of water, a disposition for the overburden, drainage for the waste water and ample grades for the flumes or sluices carrying the material. After a gravel bank is opened up, the overburden may be deposited directly on the floor or bottom of the pit provided there is means of drainage to carry off the waste water. Small levees are built up of gravel backed up with brush to retain the material and prevent overflowing. Sewer pipe or box drains are placed in the center of the pond thus formed, their tops flush with the pond level (Fig. 1).

Another method of retaining the material where disposition is made in the bottom of the pit is by means of sheerboards. This method, known as sheerboard construction, is largely used in the building of dams and fills by hydraulicking. Under many conditions it is cheaper and more effective than the construction of earth or gravel levees. In this method the material is retained by two or more small bulkheads or sheerboards made of two 1x12-in. boards, nailed to 2x4-in. stakes about 7 ft. long. The 2x4's are pointed at one end and driven into the ground on about 4-ft. centers. (See Fig. 2.)

After the material is carried up to the top of the first

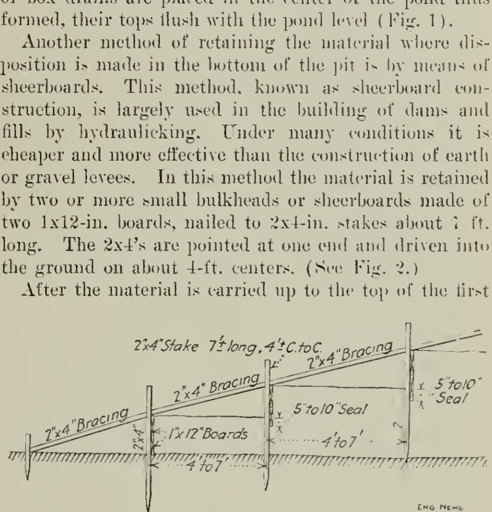

Fig. 2. Sheerboard Method of Retaining Material

row of sheerboards, a second row is built from 4 to 7 ft. back of the first. The bottom of this top sheerboard is placed from 5 to 10 in. below the top of the lower bulkhead to prevent the material from bulging and flowing out between the two bulkheads. The amount of seal necessary depends upon the nature of the material being handled. In ordinary loam 6 in. has proven effective while in fine clay or sandy loam 10 in. is often necessary. As many sheerboards are built in the above manner as is necessary to take care of the stripping over a given area. In this method the water is taken off through spillways which lead to the pipe drain or to some natural drainage course.

If no natural outlet for drainage exists it may be necessary to install a centrifugal pump to take care of this water. Where a small yardage only is required per day, it is often possible to let seepage and evaporation take care of this water, provided there is no natural outlet. However, drainage is always to be preferred and generally is a necessity. Where seepage and evaporation are depended upon to any extent, the bottom is soon silted and clogged up, resulting in the overflow of the levees and break-throughs. Where disposition is made in the bottom of the pit, the fall necessary for the flumes from the top of the gravel bank to the waste pond is generally ample.

The character of the overburden must be such as to be easily handled with water. Clay is generally a very difficult material to handle, requiring more water, greater pressure, and greater flume grades to handle than ordinary loam or dirt. The amount and size of rocks, if any, also affect the efficiency of this method.

Quantity of Water Required—No rules can be laid down for the quantity of water required per cubic yard

of material removed, pressure of water necessary and the grade of flume required, these factors depend entirely upon the nature and character of the material to be handled. There is sometimes found a fine, heavy, dead sand on top of the gravel deposit which requires nearly twice the amount of water, pressure and flume grades to carry it than the sand proper.

The quantity of water is generally more important than the pressure. Comparatively light grades can be used for the flumes if a sufficient quantity of water is present to effect complete suspension. As heavy grades as possible, however, should be used, for the greater the grade the less the dirt has to be carried in suspension, with a consequent increase in the carrying capacity of the water.

An overburden composed of soft loam with no rocks or boulders and no dead sand to contend with has been removed with flume grades of 8%, and a delivery of 1500 gal. of water per cu.yd. of material removed. A pressure of 75 lb. per sq.in. was used.

Due to the comparatively shallow working face and the consequent frequent changing of pipe connections, and flumes, hydraulicking, when applied to gravel stripping, does not show the same degree of efficiency and economy that can be obtained under the more favorable conditions of a high working face. Even under such adverse conditions, however, the economy that can be obtained by this method where the other conditions are favorable is very good.

Layout of Tracks

The track layout should permit of easy and flexible switching operations, otherwise costly and irritating delays and interference in switching are very likely to result. Wherever it is possible the main track serving the plant should have switching connections with the main track of the railway at both ends. Empty and loaded cars can then be switched without interfering with the operation of the plant. Where conditions make such an arrangement impracticable, a runaround track should be built so as to permit of switching operations while cars are being loaded at the bins (Fig. 3).

Switching Tracks—Switching tracks having excessive curvature and grades are a constant source of delay due to derailments and the inability of the locomotive to "pull" the cars [illegible] without [illegible] switching. Where conditions ... [illegible] the alignment and grades that must be used, there is often considerable latitude in the ... of which full advantage should be taken. A curve of 16° should be considered a maximum for switching tracks for road engines, while 18° or 20° is about the maximum for switching engines. Grades for the ... [illegible] should, of course, be kept as low as possible ... [illegible].

Rails—I have learned by costly experience that there is no economy in laying heavy tracks with light 56-lb. rails. The ... [illegible] that one ... [illegible] a gravel pit demands a

Fig. 3. Suggested Track Layout at Loading Bins

good track built of at least 70-lb. rails; an 80-lb. rail is better and is considered by the writer the only rail to use in tracks over which switching operations are performed. Dead-end empty storage tracks over which engines very seldom go is another matter, and here good 60-lb. relayer rails will generally answer the purpose.

Loading and Storage Tracks—Wherever conditions permit, the empty-car storage tracks above the plant and the load-storage tracks below should be on a continuous down grade, so as to permit "spotting" of the cars to the plant by gravity. Straight, empty, storage tracks should have a grade of at least 1%, and better 1½%. The short stretch of track in front of the plant at the loading chutes should have at least a 2% grade. The grade of the load-storage tracks should be at least 1%.

If curvature occurs on any of these tracks, due allowance should be made for it in establishing the grades. If the handling of cars by gravity is going to be a success and not a source of constant delay and trouble, the tracks must have sufficient grades and be so surfaced and aligned that the cars will start anywhere with one or two pinches of the car pinch-bar.

Where the capacity of a plant is 20 cars or more per day, it often pays to install a small electric-drum hoisting engine to expedite the "spotting" of the cars for loading at the bins (Fig. 4). With a [illegible] alongside

Fig. 4. Arrangement for "Spotting" Cars

the bins, a cut of two to four cars can be handled, the operator having complete control of the cut in either direction.

Locomotive and Cars—The transportation of the material from the pit to the plant is best accomplished by the use of hopper-bottom or standard bottom-dump railroad ballast cars hauled by a four-wheel switching locomotive of about 40 tons weight. The tendency here has been to use too light a locomotive. The maximum hauling capacity of a 40-ton, 0-4-0 locomotive on a 1½% grade with a track resistance (not including curvature) of 20 lb. to the ton—a figure none too liberal for the general run of gravel pit tracks—is about 420 tons.

For regular work a locomotive should be used at not more than about three-fourths of its maximum capacity. This is not only advisable from an economical point of view, but it will also lengthen the life of the locomotive and provide for emergencies and a possible future increase of output. When it is considered that even 4½% grades are often necessary in hauling out of the pit and up to the top of the track hopper, often over light and poorly surfaced tracks having excessive curvature, the necessity of using a locomotive of ample hauling capacity becomes apparent.

Preparation of the Material

Preparation of the material should begin in the bank or deposit. If the material has not a rough gradation from coarse to fine, the production of a uniformly graded material is going to be expensively difficult and nearly if not impossible. Most so-called gravel banks are really sand banks containing only a very small percentage of gravel. Moreover, the small amount of gravel contained in such banks is often extremely coarse, with a large

jumping from sand to 6-in. stone, no amount of crushing and reduction within reason is going to produce a material of uniform graduation. Too much care cannot be exercised in the examination of a deposit before operations are begun.

Graduation of Material—The producer's bank material and his market requirements often make uniform graduation extremely expensive. As an instance, the writer has in mind a producer whose deposit runs high in the ¾- to ¼-in. material. In order to produce a uniformly graded material of from 1½ in. to ¼ in., it is necessary for him to take out a large amount of this ¾- to ¼-in. material.

There is but a comparatively small demand in his market for this ¾- to ¼-in. material; as a result, this must often be sold at an actual loss; which, of course, increases the cost of production of the 1½-in. material. A well graded material, however, is generally worth the price, considering the saving that can be effected in the cement bill by the use of such material.

Fig. 5 shows an analysis of a concrete gravel produced by a plant operating in the Middle West. This gravel is 1½-in. material, uniformly graded, down to sand. This analysis shows what can be done in the matter of graduation when a plant is operating under favorable conditions. This analysis is an average of several hundred carloads, a test being made of samples taken from every three cars of material shipped on this particular contract. The dotted line (Fig. 5) shows the ideal graduation or

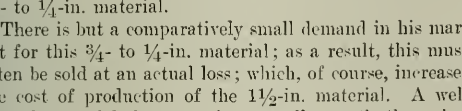

Fig. 5. Typical Gravel Analysis

mixture according to experiments by Fuller. To show the effect on the graduation of mixing sand with the material, 32% of a coarse, well graded sand was mixed with 68% of the gravel, with the results shown by the analysis curve in Fig. 5.

[A second article will describe screening and washing plants.—Ed.]

Patents on Bituminous Road Construction Since 1900*

Over 300 United States patents on road construction have been issued since the year 1900. J. H. Amies, of Easton, Penn., inventor of "Amiesite," a cold-laid asphaltic concrete, has taken out the largest number—34 patents, seven of which were taken previous to 1900. His patents apply to various processes and methods of construction, such as the use of fibrous material incorporated in asphaltic mastics; processes for eliminating heating plants by the use of benzine, naphtha and the like; processes for granulating asphalt for shipment and then heating on the work; processes for making adhesive, fragments of stone previously coated with asphalt mixtures, and numerous other combinations, mixtures and methods.

The other chief figure in patent-road construction has been the late F. J. Warren, of Boston, Mass., who took out or controlled 30 patents (1900-1911) for methods of work, etc. The best known, of course, are "Bitulithic" and "Warrenite." Mr. Warren came from a family which, for many years, had been engaged in the business of importing and handling asphalt. While connected with the street department of Newton, Mass., he first became interested in the application of asphalt to streets and roads. His first patent dates from Jan. 5, 1900. He is generally credited as being a pioneer in the construction of modern asphaltic-concrete road surfaces.

Mr. Warren's other patents relate to the use of different fluxes, using more mineral ingredients, use of asphalt for surface applications, preservative for wood paving blocks, preparing concrete aggregate for shipment, a multi-layer road construction, temporary liquifiers, a mastic to receive a loose layer of rocks, and several patents on apparatus and machinery. The "Bitulithic" pavement was originally patented in 1901, and subsequent patents were issued in 1902, 1905, 1908 and in 1909.

It would seem from a study of the list of titles that patents have been issued covering every phase of bituminous road construction from the refining of asphalt and tar to their use in any form on roads and streets, although probably by far the greater number of these patents have never been tested in the courts.

Numerous patents have also been taken out in England for the use of tar on roads, although tar was applied to macadamized roads in London as far back as 1820. Until recently the tar used came from gas works without refining. Now, there are several costly plants in England for refining tar for highway uses and the product is placed on the market under such trade names as "Tarmac," "Tarvia" (which is also made in this country by the Barrett Manufacturing Co.), and many others. Generally, patents are on materials rather than processes.

*From information supplied by J. B. Gray, 135 N. Ave. 62, Los Angeles, Calif.

An Early Patent for a Grouted Concrete Pavement—In January, 1829, a British patent was granted to one William Hobson, Gent., for an improved method of paving streets, described in the "Journal of the Franklin Institute" of that period as follows:

Instead of picking up the ground loose (as is the practice in the present mode of paving), ram the ground on which the paving is to be placed, well down, until it is as solid as possible, to a form corresponding with the form of the surface the paving is to take when finished. The stones shall be sorted so as to be nearly of an equal depth; mix up gravel or small fragments of stone with lime and water into a composition or kind of coarse mortar, and lay a bed (of sufficient thickness, to allow for the irregularity of form in the bottom of the stones) of this composition, on the ground which has been previously rammed, and in this composition place the paving stones, and grout them full with finely sifted gravel or coarse sand, mixed up into a liquid state with lime and water, in the same proportions as the composition the stones are laid in.

All the paving done in one day must on the same day be well rammed to an even surface, and when so done must again be grouted full, with fine gravel or coarse sand, mixed up with lime and water, as before. This must be done with each portion of paving on the same day on which the paving is executed; and this method of ramming and grouting must be followed up on each day as the paving proceeds, and when so done it would (if practicable) be desirable that the part paved should be left without carriages being permitted to go over it for three or four days, in order to let the composition of lime and gravel, or stone, set and harden, and it will then become firm and solid, and, if the lime is of a proper quality, impervious to water.

This method if applied to paving done with pebbles or unsquared stone, will be found advantageous in a proportionate degree to paving done with squared stones. I recommend that the lime to be used in this method of paving should be stone, or gray chalk lime, as lime of that description will set and harden in water, and if of a good quality the proportions of one measure of lime to four or five measures of gravel or small fragments of stone will be sufficient.

Two Striking Steel Bridges on the Lake Erie & Eastern R.R.

Two of the steel bridges on the new double-track Lake Erie & Eastern R.R., in Youngstown, Ohio, contain various strikingly original features. Both happen to be skew bridges, but to secure square-ended running track they are detailed with square ends. The constructive arrangement of these ends is different in the two cases. Further, one of the two bridges—the plate-girder bridge, Figs. 1 and 2—has a remarkably individual floor construction. There are other novelties in general design, details and equipment, the latter including fender girders to protect the trusses from effects of derailment, and blast plates over railway tracks below to protect the underside of the bridge from the abrasive action of locomotive exhaust.

Three-Span Plate-Girder Bridge with Continuous Expansion

About opposite the center of Youngstown, just south of the city water-works filter plant, the line crosses on a skew over the Baltimore & Ohio R.R. The latter has two main tracks and two sidings at present, but may later add two more main tracks. To fit this condition, the crossing is designed with a middle span over the four main tracks, and on either end a span over the siding. The abutments were built square, while the piers are necessarily skew, as shown in Fig. 1.

On account of the floor-construction, noted below, it was necessary to avoid expansion movements between the several spans. The three spans are coupled together by having sole-plates continuous under adjoining shoes,

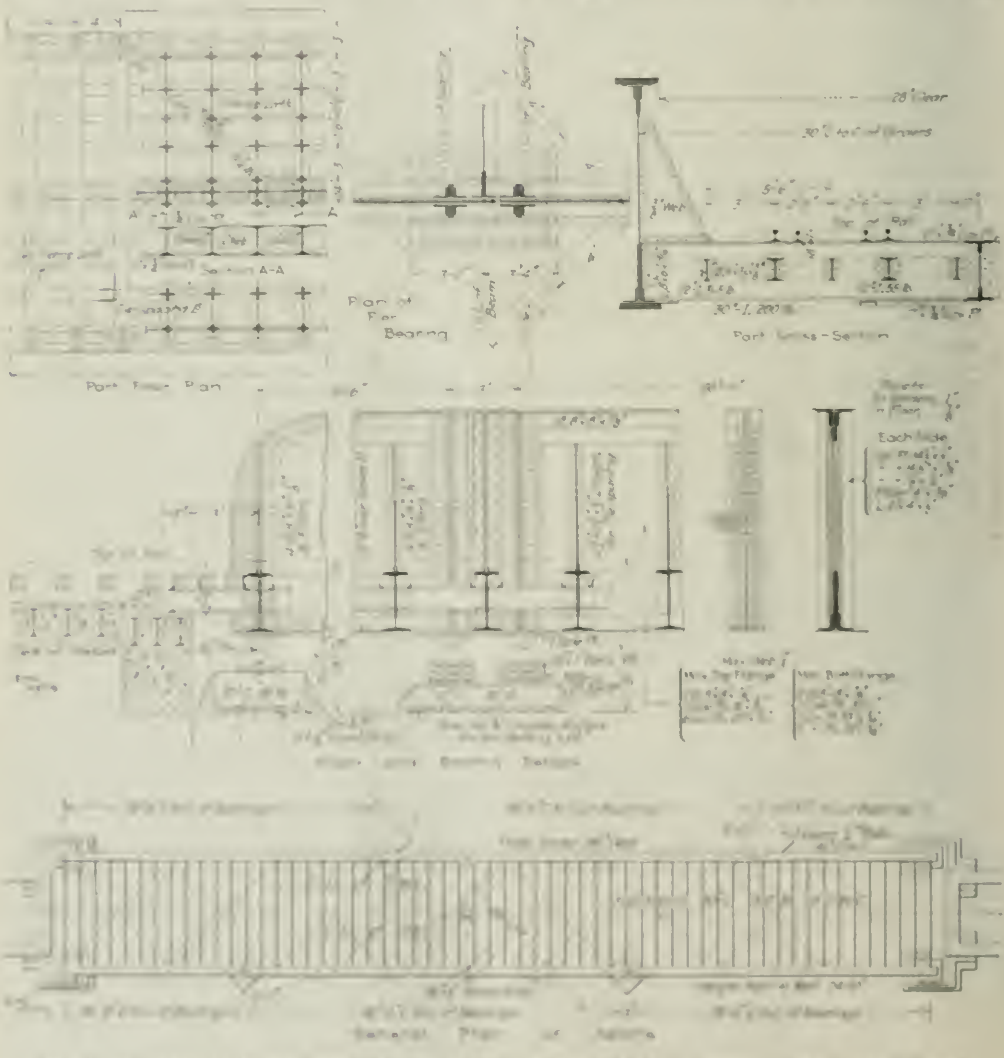

Fig. 1. Three-Span Plate-Girder Crossing over Six-Track B. & O. Railroad; Lake Erie & Eastern R.R., Youngstown, O.

and only the two bearings at one end are fixed, while the other six are expansion bearings. A detail in Fig. 1 shows the connection of adjoining spans at the shoes.

FLOOR CONSTRUCTION—The floor of this bridge consists of 30-in. I-beams at 4-ft. spacing, as floor-beams, and short I-beam stringers cut into the 4-ft. panels. There are four stringers per track, with a view to supporting the ties in such complete manner as to practically prevent the chance of breaking through the floor in a derailment.

The use of what is equivalent to bridging in the floor is a novelty in steel bridge work. Along the longitudinal center line of the bridge a strong longitudinal girder is formed by cutting in longitudinal diaphragms between the floor-beams and riveting a flange-plate on top and on the bottom the full length of the bridge. A thorough distribution of loading among the floor-beams is secured by this artifice. The flange-plates of the longitudinal girder are riveted to the diaphragms only, and not to the floor-beam flanges, as nothing would be gained by also attaching to the latter and their flanges would be weakened.

Another novelty is the provision of angle clips on the tops of the stringers to form abutting blocks to locate the ties. This not only holds the ties in position but prevents their being placed so close to the floor-beams as to form dirt pockets.

The laterals of the bridge are channels laid flat and placed underneath the stringers. They are supported at each end and at the crossing by attachments to their gussets, but in addition, to prevent rattling, are pinned to a stringer at an intermediate point by plate clips.

There is a break in grade on the bridge just over one of the piers. This, of course, suits only the girders on one side, while for the girders on the other side the break in grade comes within the length of a span. On this side, the attachment of certain floor-beams had, therefore, to be adjusted, both in the angle between web of floor-beam and the vertical line of the girder, and in the seating plate or gusset between bottom flange of floor-beam and bottom flange plate of main girder. These seating plates had to be planed to the proper taper (0.3%). All floor-beams are set with webs normal to the grade of track; that is, where track is level the webs are vertical, while where track is on 0.3% grade the webs are normal to this grade line.

The piers of the bridge are in alignment with the skew; this arrangement involves minimum interference between the masonry and the clearance of the tracks under the bridge. The grillages resting on the piers, however, are set parallel to the bridge axis and therefore run approximately on the diagonal of the pier. This is shown in the pier-top detail in Fig. 1.

The connection between the ends of the bridge and the abutments is made by short outside stringers which rest on a ledge of the backwall of the abutment; thus there is room under and back of the steel to get at it for painting, etc.* These stringers can carry a tie close up to the curb tie of the abutment. The drawing makes this arrangement clear.

FIG. 2. DOUBLE-TRACK CROSSING OF LAKE ERIE & EASTERN OVER B. & O. RY., YOUNGSTOWN, O.

(Three spans are joined so as to expand together, with fixed bearings at one end. The ends are square, the intermediate supports skew. The floor-beams are 30-in. I-beams, 4 ft. apart, stiffened at midlength by "bridging" formed by a steel longitudinal girder. There are four stringers per track.)

Over each of the six tracks of the B. & O. R.R., a steel blast-plate is attached to the under side of the bridge in order to protect the steel from the abrasive action of the locomotive exhaust. The same device is used on the truss spans of the Mahoning River No. 1 crossing, which crosses a number of railway tracks, as described just below. These plates are attached in a manner to allow renewals to be made when they are worn out.

FOUR-PANEL TRUSS SPANS AT YOUNGSTOWN PUMPING STATION

The first crossing of the Mahoning River is made by a series of plate-girder spans continuous with a plate-gir-

*This same object was kept in view throughout the design of the bridges of this railway. Thus, large cast-iron and steel pedestals are used on all of the bridge-seats, for the same purpose of giving ample working-room around the steelwork.

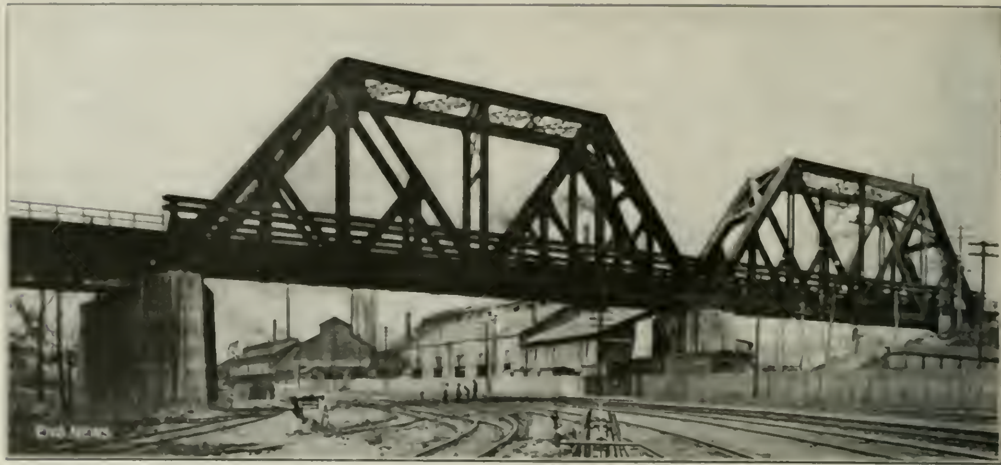

FIG. 3. VIEW OF THROUGH-TRUSS SPAN OVER RAILWAY TRACKS AT MAHONING RIVER CROSSING NO. 1, LAKE ERIE & EASTERN R.R.

der viaduct over the territory of the filter plant of the Youngstown water-works. Just north of the river a series of eight railway tracks is crossed alongside the city's pumping station. For this crossing two through-truss spans of 192 ft. are employed. They have a number of ingenious and original features.

The spans are skew, but their stringers are made to end square. At either end of the set of two spans, the main abutment is built square and carries the stringer ends. As in the case of the B. & O. crossing, this is done

FIG. 4. MAHONING RIVER CROSSING; ELEVATION AND PLAN OF TRUSS

[illegible]

merged into a single stringer-panel, the stringers, part in one span and part in the other, are not supported at the pier. This arrangement is shown by the plan and elevation in our drawing, Fig. 4.

The general outline of these trusses is quite unusual. A four-panel truss is used for the 192-ft. span, giving main panels 48 ft. long. These are subdivided, however, by a hanger-and-substrut system, so that the floor panels

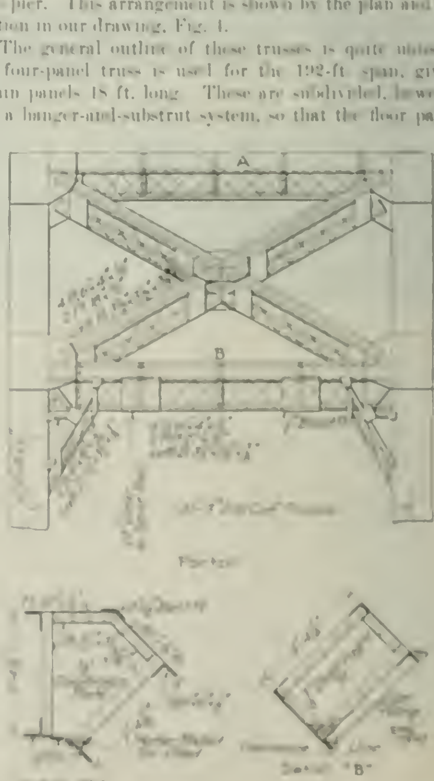

FIG. 5. MAHONING RIVER CROSSING; DETAIL OF PORTAL BRACING

are 24 ft. long. The photograph, Fig. 3, shows well the peculiar chunky appearance of the resulting structure.

Fender girders or "skid girders" are used on this

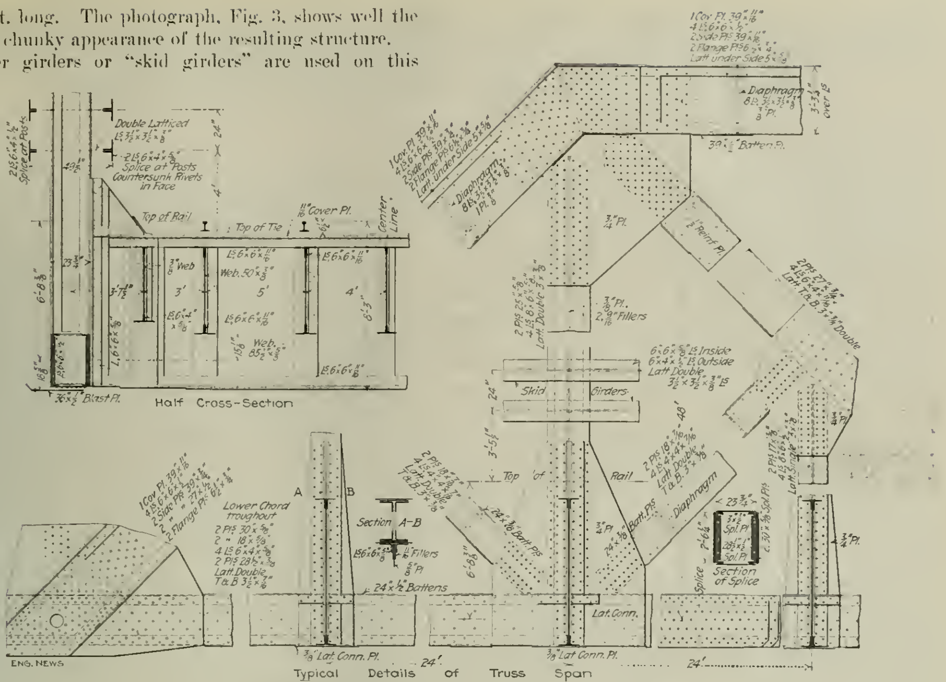

FIG. 6. MAHONING RIVER CROSSING; DETAIL OF TRUSS

bridge in precisely the same arrangement as used on the great Beaver bridge of the Pittsburgh & Lake Erie R.R., built some years ago. A double line is used, 2 ft. apart vertically, the lower one being 4 ft. above the base of rail. The flanges of each of the girders are made continuous from end to end by splices at all posts; the trackside face is made smooth by putting the splices inside and countersinking all rivet heads on the face.

The floor arrangement includes seven stringers: four rail stringers (one under each rail), a middle stringer, and two outer stringers. Thus both ends of the tie are supported. This arrangement, similar to common practice on the Pittsburgh & Lake Erie R.R., is adopted to reduce the chance of any destructive effect of derailment upon the floor, just as the skid girders are intended to protect the trusses.

A further item of protection against derailed equipment is the provision of spacer-blocks between ties. The standard width of space is 3 in. The blocks are attached to the side of the tie and extend from top to bottom of tie. Three blocks are used in each space.

The two spans being connected by their stringers, no relative expansion movements are permissible at the central pier, just as in the case of the B. & O. crossing. The solution is different, however. The fixed support is on the central pier, and the bearings at both abutments are expansion bearings. At the central pier the abutting ends of the trusses are carried jointly on a single riveted pedestal, as sketched in Fig. 4.

Some of the detailing is shown in Fig. 6. As will be seen there, the details are typical for heavy riveted bridge construction. Novelties are found in the use of narrow reinforcing bars on the front and rear edges of some of the chord battens, in the use of asphalt filler to eliminate any water pockets as, for instance, in the portal struts, and in the use of blast-plates over the tracks below. These plates are steel 36x½-in., riveted below the lower lateral system, with support at stringers and laterals.

The portal construction is exceptionally heavy. The lower strut is additionally supported by small brackets in the corners of the clearance diagram. All latticing here is of angles (Fig. 5).

These bridges were designed by Albert Lucius, Consulting Engineer, New York City, for the engineering department of the Pittsburgh & Lake Erie R.R., under J. A. Atwood, Chief Engineer, A. R. Raymer, Asst. Chief Engineer.

The First Concrete Pavement Constructed in Schenectady, N. Y., which has recently been completed, has some interesting features. It is a one-course pavement, 7 in. thick, of 1 : 2 : 4 concrete, made of crusher-run stone graded to 1 in. in size. Expansion joints are placed at an angle of 75° to the curb. William B. Landreth, City Engineer, writes to us, under date of Oct. 27, that "while theory could easily prove that there is no advantage in placing the joints at an angle to the curb, we have decided to give the diagonal joint n practical trial. It is not straining anyone's credulity, however, to believe that the weight of a vehicle may be carried across such a small depression on three wheels." The street is 24 ft. wide, and these expansion joints are placed every 20 ft. These expansion joints are ½ in. wide and are filled with several varieties of joint filler, the intention being to observe the action of these various fillers during the fall and winter, in hopes of finding the most suitable one for the given conditions. In constructing the pavement, the gutters have been made deep enough, and the crown of the pavement is of a shape, that when the pavement is worn to an extent to make repairs no longer economical, the city will be able at moderate cost to place on the old concrete a 2-in. asphaltic-concrete surface. This is the first real concrete pavement in the city, although a short experimental strip was built some years ago.

Kansas City Specifications for Creosoted Wood-Block Paving

By Clark R. Mandigo*

SYNOPSIS—The new specifications for wood-block paving of Kansas City aim to cover more completely and thoroughly than usual the treatment of blocks, this being recognized as a key to the successful pavement. The care of and method of laying the blocks on the street are also covered fully. A few extracts from the specifications are included, but the major part of the article is a discussion of the principal specification clauses and the reasons therefor. A method is described of utilizing wood-block on grades of 5 to 8% by use of special open joints.

In general, specifications for creosoted wood-block paving are indefinite in many of the essentials, as though the engineer preferred to place the responsibility on the block manufacturer and the contractor. This is especially true in the clauses covering the creosote oil and the methods of treatment, and accounts in a measure for the variation in quality of different pavements in the same city.

Kansas City's creosoted wood paving block specifications were open to these objections, although a number of pavements with only minor defects had been laid under them; and now that the ten-year maintenance guarantees on most of the asphalt pavements in the heart of the retail district of the city are expiring, it has been decided to repave immediately with wood blocks, instead of attempting to repair the worn-out sheet asphalt surface.

In redrafting specifications for wood block, an attempt has been made to insure first-class construction in every particular by rational and economical methods, to eliminate as far as possible the nuisance of bleeding, buckling and slipperiness.

Specifications

A few of the more important specification clauses are here given.[1] These and others are discussed in detail in the following columns:

Blocks

TREATMENT—The method of treatment must be thorough and up-to-date, including the necessary air-tight [illegible]

[illegible] any point less than 2[illegible] but more than 10[illegible] lb. per sq.in. and maintained at that figure long enough for the wood to absorb the specified amount of oil. The temperature of the oil after entering the cylinder shall at no time be less than 1[illegible]° F. or more than 2[illegible]° F. The blocks after treatment shall show a satisfactory penetration of oil throughout. All blocks which are in any way defective or which have been badly warped or checked in the process of treatment shall be rejected. Before removing the charge from the cylinder, the blocks shall be given a steam bath lasting at least one-half hour to clean off all the surface oil.

INSPECTION—The manufacturer shall furnish all apparatus necessary for tests and all labor which may be required in removing material for examination. [illegible] tanks and treating cylinders shall be provided with necessary gages, thermometers, draw-off cocks, etc., affording adequate means for determining the absolute weight of oil retained in the blocks. The contractor shall furnish a copy of the plant record showing a complete statement of each operation in the creosoting process.

Foundation

MORTAR CUSHION—Upon the concrete foundation, which has previously been cleaned, there shall be spread a layer of sand and portland cement mixed in the proportion of one part cement to four parts sand. The cement and sand shall be mixed dry until the mixture has a uniform color throughout and shall be spread on the foundation not less than [illegible] in. nor more than 1 in. in thickness, the depth being sufficient to bring the wood blocks to the finished grade of the street, as shown on the plans. The mortar cushion shall be carefully shaped to the true cross-section of the roadway by means of a properly made template covering at least one-half the width of the portion of the street to be paved. The template shall be drawn along guide rails or wood strips placed next the curb and in the center of the street, which have been carefully laid to grade. Where there are street-car tracks on the street, they may be used as a guide for one end of the template. After the blocks have been laid on the cushion prepared in the above described manner, and after they have been rolled, but before any filler shall be placed, the surface of the pavement shall be thoroughly wet so that the mortar cushion may receive enough moisture to cause the cement to set.

Wearing Surface

EXPANSION JOINTS—Before commencing the laying of the blocks, boards [illegible] shall be set on edge next the curb. Any projections or unevenness on the face of the curb shall be removed so that the board will fit snugly against the curb. After the blocks have been laid and rolled as hereinafter specified, these boards shall be removed and the space [illegible] shall be cleaned out and filled flush with the top of the blocks with asphaltic cement. All joints around manholes, sewers, catchbasins, valve boxes, etc., shall be filled with asphaltic cement at the same time.

LAYING BLOCKS—When delivered on the street, the blocks must be closely piled and covered to protect them from [illegible] exposure to the weather. [illegible]

*Assistant City Engineer, Kansas City, Mo.

[1]In general, the specifications are identical [illegible]

FILLING JOINTS—On the portions of the pavement where no transverse joints are specified, the joints shall be filled in the following manner: When the pavement is dry, and after it has been swept clean of all dirt, sticks and rubbish, the expansion joints and joints around manholes and catch-basins shall be filled with asphaltic cement, as hereinbefore specified.

SAND FILLER—The joints in the body of the pavement shall then be filled with clean Missouri River sand, heated to a temperature of at least 300° F. and swept back and forth across the pavement until all the joints are full. A slight excess of sand shall be left on the surface of the pavement after the joints of the pavement are filled, to be removed by the contractor without additional compensation, as soon as directed by the city engineer.

ASPHALT FILLER—The joints in the body of the pavement shall then be filled with an asphaltic cement, heated to a temperature of at least 350° F. and squeegeed into the joints with hot iron squeegees until they are full, and all surplus asphalt carefully brushed off the surface of the pavement. A coating of coarse sand or Joplin chats, heated to at least 300° F., shall be immediately whipped into the surface of the pavement, any surplus to be later removed if so required by the city engineer. Where a bituminous filler is used, the filling of the joints shall be done only in clear, dry weather, with a temperature of the air not less than 50° F.

TRANSVERSE JOINTS—Where shown on plans, which will usually be where the street grade exceeds 3½%, transverse joints shall be made by placing an ordinary building lath on edge between each row of blocks, laid at right angles to the curb, and laying the blocks closely against the lath. A slight joint shall be left between the ends of the blocks in each row. It is important that the rows of blocks shall be set as closely against the lath as possible and that the rows are straight. To this end, the rows of blocks must be driven up tight with a sledge and plank at least every fifth row of blocks. The pavement shall then be rolled as hereinbefore specified and all imperfect blocks replaced.

All of the materials entering into the pavement are first specified, followed by an account of the manner in which these materials are to be handled to form a completed pavement. This is a logical separation, but one which is not followed in any other city specification the writer has seen. It makes possible a more clearly worded specification and one in which actual operations of laying the pavement follow one another in close order. While this may not be considered important by some, it is certainly convenient and lessens the probability of the street inspector overlooking some detail which might be lost in the laboratory and plant tests as in the ordinary form of specifications.

OLD FOUNDATIONS—A great many of the streets to be repaved in Kansas City have a foundation in which a local natural cement was used. These foundations are weak at best; all lack uniformity and most of them can be removed with pick and shovel. By allowing the broken concrete from the old foundation to be used as aggregate in the new work, considerable is saved on the cost of foundation, even where additional thickness is required.

WOOD BLOCKS—In regard to the blocks themselves, it is believed that a partially seasoned timber will treat better and wear better than wood which has been thoroughly air seasoned. A seasoning of from four to six weeks is about right.

No 3-in. depth blocks have been used to date. All of the old pavements had 4-in. blocks, while pavements laid the past year, with one or two exceptions where 4-in. blocks were used, have been of 3½-in. blocks.

Only yellow-pine timber is allowed, as this has proved to be most durable, while other woods require different methods of treating, which have not yet been satisfactorily worked out.

TREATMENT OF BLOCKS—In the writer's opinion, the method used in treating blocks has a great deal more to do with subsequent trouble with swelling or bleeding than is generally believed. Anyone familiar with the operation of various creosoting plants knows that the methods in each differ considerably as does the product.

Most city engineers leave the process of treatment entirely with the manufacturer. This is not good practice, as the time in the cylinder is often a very important element. During the rush season, the plant superintendent who wants to make a good showing is liable to omit the initial steaming, force the pressure rapidly and as high as possible, and hurry the whole process. This will crowd the oil into the outside of the block and the pavement is almost certain to bleed badly, and a great deal of the oil is lost under traffic, after which the blocks absorb water and buckle.

With a timber about four weeks from the mill, a steaming of at least two hours should be required with the privilege of continuing it to four hours if thought necessary.

FIG. 1. PLANT TEST RECORD OF WOOD PAVING-BLOCK TREATMENT, KANSAS CITY, MO.

Following this with at least 24 in. of vacuum will remove most of the sap and resinous matter as well as air in the pores of the wood. If this vacuum is destroyed by the admission of the oil and not air, the wood is in favorable shape to get the best penetration.

If, however, the pressure on the oil is run up rapidly—close to 200 lb.—and a pure distillate oil is not used, the pores of the wood become clogged and the heavier portion of the oil remains near the outside of the block. The pressure should be put on gradually and should not be allowed to exceed 130 lb. for a 16-lb. treatment.

A final steam bath after the oil is drained off will clean the blocks and make them easy to handle on the street. A clean block will also take an asphalt filler better.

With such treatment and an oil as described in the

specifications,* almost perfect penetration is obtained. No nuisance is experienced from bleeding even with street temperatures well above 100° F. There will be some bubbles of oil appearing on the surface of the blocks during the first summer, but there will be none of the mixture of tar and sand, which tracks over the sidewalks and into stores.

PRESERVATIVE OIL—There has been considerable discussion recently over the use of a pure distillate oil, the claim being made that with such an oil, all chance of bleeding is eliminated. There is no doubt that such an oil penetrates the wood better, and being free from the heavy coal tar lessens the tendency to bleed; but if the methods described above are not followed at the creosoting plant, even this more expensive oil will bleed. While Kansas City has not tried a pure distillate oil, it has good success with the creosote-coal-tar-oil, the so called "doped oil," of specific gravity between 1.08 and 1.10. The 1.12 to 1.14 oil, specified until recently, caused too much bleeding.

It is admitted, however, that the weakest point in the present specifications is the one pertaining to the oil, and it is hoped that enough time can be devoted to a thorough study of oils this coming winter to much improve this section. It is difficult to write an oil specification which will be entirely open, giving each manufacturer an equal chance, and at the same time making it impossible for anyone to furnish an oil complying with the specifications, but not having all the good qualities desired. An oil entirely unsuitable for paving-block purposes, from the standpoint of preservative and staying qualities, could probably be furnished, which would comply with all the requirements of the present specifications.

PAVEMENT CONSTRUCTION

FOUNDATION—The streets in Kansas City carrying numbers of heavily loaded trucks and wagons are being repaved on an 8-in. portland-cement foundation. On account of the increasing speed, as well as weight of loads, absolute rigidity in the base is essential, and while a 6-in. foundation may be ample to support a quiescent load over a considerable area of soft or weaker subgrade, it does not have mass enough to absorb the vibration and shaking due to the rapid passage of a heavy load and may fail under impact. With the ever-increasing use of trucks it behooves municipal engineers to be on the safe side in laying pavement, the foundation of which should be good for from 30 to 50 years.

[illegible]—It will be noticed in the specifications that the mortar-sand cushion is mixed and laid dry, the water not being added until after the blocks are rolled. This enables the roller to bed the blocks better and get a smoother surface. A mortar-sand cushion should be used [illegible] under all wood blocks, whether along street-car tracks or not.

[illegible]—The blocks when delivered on the street should be closely piled and frequently sprinkled [illegible] in the Engineering News. It is not possible in most cities to lay the blocks directly after coming from the treating cylinder; [illegible] the hot sun and wind during shipment and

before laying will soon begin to check them and start the oil on all sides. Piling them close and sprinkling them will keep them cool and normal, more nearly the conditions they will meet after being laid.

EXPANSION JOINTS—All of the expansion joints necessary should be placed between the curb and the first row of blocks. Placing a longitudinal row of blocks between two expansion joints, as is sometimes done, is bad practice, as the single row of blocks will be almost certain to be raised up above the balance of the pavement as the expansion joints close up. Throwing a longitudinal joint any farther from the curb will be a detriment on account of wear.

If the blocks are hammered tight sidewise, in laying, they furnish each other lateral support in the direction of traffic and by friction between the rows materially reduce transverse expansion. A slight joint at the ends of the blocks allows for good penetration of the filler and transverse expansion.

There is no apparent advantage in laying the blocks at an angle to the curb, except possibly on a narrow roadway where vehicles track one another, while the right-angle method is cheaper. Straight rows are also important so that each row of blocks may act as a straight column under compression caused by expansion forces.

JOINT FILLER—On heavy-traffic streets, a sand filler has usually been specified. The sand should be coarse grained. Fine, round-grained sand has no place in any pavement. It should be applied hot and worked back and forth with wooden pushers until the joints are full. If the joints are close, a sand-filled pavement under heavy traffic will soon seal itself and iron out smooth and waterproof.

There is, however, a risk in using sand filler. Since small portions of the pavement may not get traffic, or weather or street conditions immediately following its completion may not be favorable. Municipal engineers, as a rule, believe that a bituminous filler is best for creosoted wood-block pavement, but they are troubled with the difficulty in getting it into the joints where it belongs without leaving a sticky carpet on the surface. By the use of a pure asphaltic cement, with a high melting point and low penetration, put on as described in the specifications, a great deal of the trouble usual with a bituminous filler can be avoided.

The asphaltic cement described* is very tough and rubbery at ordinary temperatures, and is not cut back materially by the creosote oil. It should be heated hot enough to run like water, and be immediately broomed back and forth across the surface of the pavement with hot iron squeegees. These squeegees are made of a slightly curved piece of ¼-in. steel plate about 18 in. long by 2 to 3 in. wide, fastened and braced to an asphalt rake handle.

At least four squeegees should be on hand and they should be kept hot in the fire pot of the asphalt kettle, two being in use while two are heating. If these are used with skill, even the smaller joints in the pavement can be filled with asphalt and only a very thin coating left on the surface of the pavement.

Immediately after filling the joints a slight coating of very hot coarse sand or dust should be wrapped into the surface. The sand should be hot enough to melt the

*[illegible]

*Penetration at 25° C. with a No. 2 needle, weighing with 100 grams, in 5 sec., not more than [illegible] nor less than [illegible] [illegible] melting point not less than [illegible] C.—Editor.

asphalt remaining on the surface, and not too much should be used so that there will be no surplus to be removed later. It is obvious that this method of applying filler will reduce to a minimum any chance of a sticky surface.

Wood Block on Steep Grades

In Kansas City, nearly all streets have some stretches of more than 3½% grade. If creosoted wood blocks were, therefore, to be used successfully, some method had to be devised for preventing slipperiness on grades. The city has adopted, with some changes, the method introduced by A. H. Stone, Assistant Engineer of the Kansas City Terminal Ry., in the paving of some of the railway's viaducts. The writer understands that this same method of laying blocks on grades was first used in Vancouver, B. C.*

Special Joint Filler—The method consists of laying a line of ordinary building lath on edge on the sand cushion between each row of blocks, and filling the balance of the joint with stone chats and asphalt after the blocks are rolled. Pavement of this kind has been used successfully on grades of 5 and 6% and there is no reason why it should not be used on grades as high as 8 to 10%.

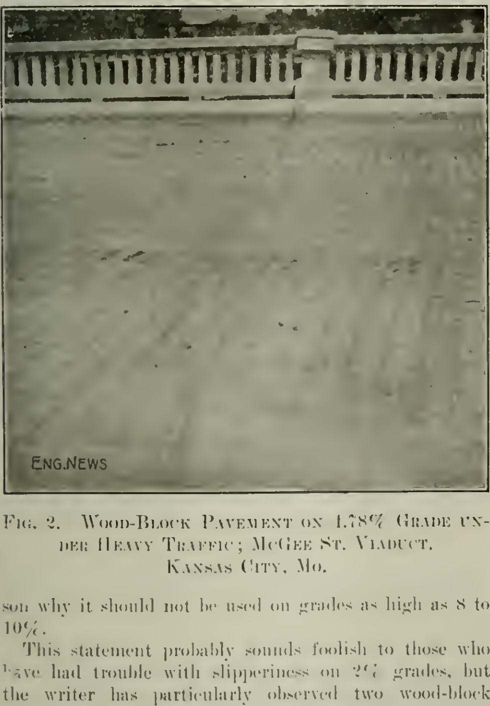

Fig. 2. Wood-Block Pavement on 1.78% Grade under Heavy Traffic; McGee St. Viaduct, Kansas City, Mo.

This statement probably sounds foolish to those who have had trouble with slipperiness on 2% grades, but the writer has particularly observed two wood-block pavements laid with lath joints on 4.78% and 5.17% grades, and subjected to considerable traffic and one short stretch of 11% grade, for more than a year, under all weather conditions; and he has never seen nor heard of a horse falling on any of them.

There is no uncertainty in a team on one of these streets, even with a heavy load; there is no quivering of the horses' legs due to an insecure foothold, but a straight, deliberate, hard-pulling walk possible only when a team is sure footed.

A wood-block pavement laid with lath joints, in the writer's opinion, offers a much better foothold than sheet asphalt or even tar-filled vitrified brick.

Filling Joints—In constructing the open-joint pavement, the rows of blocks must be frequently sledged close to the lath and straight rows obtained. The broken stone which is placed in the joints should be of practically one size and of the largest size that can be swept into the joint. Stone grit should be screened over a ⅜-in. screen before heating, as any fine material in the stone prevents the asphalt penetrating to the bottom of the joint.

The asphalt filler should be heated and applied in exactly the same manner as described for the close-joint pavement in order that there shall be no surplus left on the surface of the pavement.

It is expected the open-joint pavement will not wear quite as long as one with close joints, although at the end of two years there is no evidence to support this. The joints are packed solid and remain nearly flush with the surface of the blocks. The blocks are very firmly bedded and the joint is so small that it is not picked out nor are the edges of the blocks broomed down more than in the ordinary pavement.

There is no fixed rule for the grade at which to change from close to open transverse joints, as this will depend entirely on local conditions as to the general grade on the street to be paved, the class of traffic, the kinds of grades and pavements the local teamsters are accustomed to, and general weather conditions.

Conclusions—Kansas City offered a particularly unfavorable field for creosoted wood-block pavement on account of the topography, practically all streets having some stretches of grades of 4% or greater, while many exceed 6 or 7%. There are long, hot, dry spells during the summer; and no street sprinkling is done by the city.

The entire cost of the paving, repaving or repairing, after the expiration of the guarantee, is assessed in special tax bills directly against the abutting property; so that any attempt to lay a high-priced pavement was met with opposition, until the new pavement could be proved to be cheaper in the long run and entirely satisfactory.

By the use of a heavy foundation, and a mortar-sand cushion, rigidity of the base is obtained, which will hold the block surfacing absolutely true to grade and crown. The 16 lb. of 1.10 oil per cu.ft. of timber, injected clear through the blocks by the method of treatment described, prevents decay and partially waterproofs the block, without, at the same time, causing any nuisance from bleeding. The lath transverse joints will prevent slipperiness on grades; and the asphalt filler waterproofs the surface, preventing swelling and buckling; and if placed as described, does not make an objectionable sticky mass on the surface of the blocks.

There are undoubtedly many points in the laying of creosoted wood-paving blocks which have not been touched upon and many things in the specifications offered which may require changing, especially if they are to apply under different local conditions. They are offered more by way of suggestion than as absolute rules. They are, however, the outcome of careful experiments, in which all of the methods described have been used with success.

*The same method of laying wood block on grades is now being used extensively in Detroit, Mich., where many old granite block pavements are being replaced with creosoted wood-block.—Editor

Winter Stream Measurements in Western Canada

By P. M. Sauder*

SYNOPSIS—This is a description of some interesting stream measurement work under particularly disadvantageous conditions. It forms a valuable supplement to previous articles in ENGINEERING NEWS: *"Determination of Stream Flow during Frozen Season," by C. Robert Adams, Feb. 2, 1911; "Gaging Minnesota Streams in Winter," by W. G. Hoyt, Sept. 12, 1912; "Methods of Estimating Stream Flow When Streams Are Frozen," by W. G. Hoyt, Apr. 10, 1913; and "Stream Flow Gaging under Winter Ice Conditions," by Chester Wason Smith, June 19, 1913.*

The work referred to in this article is that being done by the Irrigation Branch of the Government of Canada, in the Provinces of Alberta and Saskatchewan. All the larger streams in this territory have their sources in the Rocky Mountains. They flow in an easterly or northeasterly direction and after emerging from the foothills converge into two large streams, the North and South Saskatchewan Rivers.

There are, of course, a large number of smaller streams, which drain the prairies and empty into these two rivers; but while some of them have quite a large flow during the early spring, and during wet seasons, the flow, if any, is always very small during the winter months. Even the flow of the larger streams is comparatively small during the winter months.

The Bow River at Calgary, Alberta, may be taken as typical of the streams heading in the mountains, and which receive special attention during the winter months. Its flow ranges from a minimum in the winter of about [illegible] sec.-ft. to an average high-water flow of about 10,-500 sec.-ft. in summer, and the highest known flood due to the combined effect of warm weather melting the snow in the mountains, heavy rains and a cloud burst, is estimated at 51,000 sec.-ft.

*Chief Hydrographer, Office of the Commissioner of Irrigation, Calgary, Alta., Canada.

FIG. 1. OPEN-WATER RATING CURVE FOR SPRAY RIVER NEAR BANFF, ALBERTA

(This open-water curve is based on readings made during [illegible])

FORMATION OF ICE AND ICE CONDITIONS

Perhaps the greatest difficulties in the measurements are met with in the early part of the winter, just as the streams are commencing to freeze up. Especially is this true in the swift-running streams in or near the mountains. Needle and anchor ice often forms in large quantities in rapids, and flowing in masses [illegible] the water, make gagings very difficult and unreliable. Even after a permanent ice cover is obtained at the gaging station, the ice will, in some cases, obstruct the channel below the station and cause "backwater."

A further difficulty is that the surface ice usually forms along the edges of the stream for some time before forming in the center of the channel. At first, this may be broken away if the stream is small and open water measurements made, but later it is necessary to take some observations through holes in the ice along the edge. At

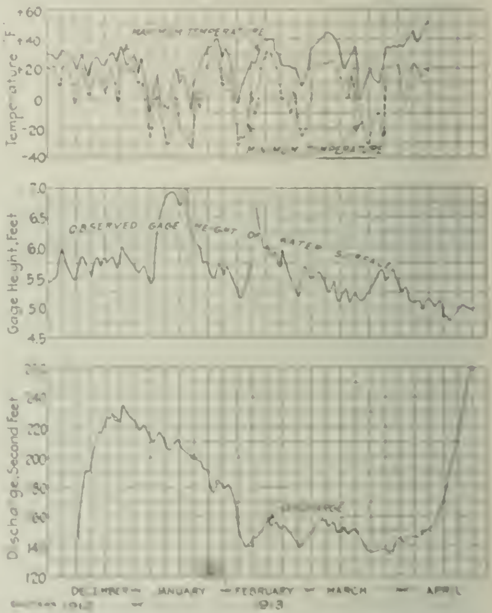

FIG. 2. OBSERVATIONS OF GAGE HEIGHTS ON SPRAY RIVER NEAR BANFF WITH CORRESPONDING MAXIMUM AND MINIMUM TEMPERATURES AND THE ESTIMATED DAILY DISCHARGES FOR THE WINTER 1912-1913

(The circles on the discharge curve indicate actual discharge measurements. Note the rise in gage height in January and February when the temperature was lowest and the discharge measurements showed that the flow was decreasing.)

the streams get farther away from the mountains their velocity decreases, and fewer rapids occur along their course. There is then less trouble with needle and anchor ice, and a permanent ice cover forms much more quickly.

In many cases the section used during the summer is very unsuitable for making measurements during the winter. It may be: (a) too wide and shallow or flowing in two channels during the winter, due to low water; (b) partially open due to swift-running water or warm water running in; (c) affected by needle and anchor ice either by flowing in the water, or causing backwater; (d) located where the snow drifts over the ice to a great depth; (e) that it is likely to have a rough ice cover or pile up with ice, due to swift water and a rough bed; (f) that there is a tendency for ice jams to occur, with consequent backwater, etc.

The typical curve, however, differs from that obtained from an open-water observation in that it is drawn back more at the surface, owing no doubt, to greater friction between the ice and the water as compared with the water and the atmosphere. As a result there are two points in the vertical at which the thread of mean velocity occurs under an ice cover. These points are near 0.2 and 0.8 of the total depth below the bottom of the ice, and the mean of the velocities at these two depths will give fairly accurate results; but when close estimates of the discharges are required, and the conditions are not very favorable, the vertical-velocity method should be used.

It is found that when all the holes are opened on a small swift stream, there are sometimes vertical pulsations of the water in the holes, which affect the velocity readings. This can usually be avoided by only opening one hole at a time, and filling it in again with ice and snow as soon as the observation is finished. It can also be overcome by inserting a thin sheet of galvanized tin or iron at the bottom of the hole, after the meter has been lowered into the water. The meter should always be held near the upstream side of the hole.

FIG. 3. GAGING STATION ON PIPESTONE RIVER NEAR LAGGAN, ALBERTA, IN EARLY WINTER 1912-1913

It is, therefore, often necessary to choose a new section for winter observations. This should be done before the freeze-up, for then, the width, depth, uniformity of flow and conditions above and below can be easily noted. The most suitable stations for winter measurements are those which have a long stretch of very smooth, sluggish water above, and a rapid fall below.

Discharge Measurements

In winter as in summer, the daily discharges of a stream are computed from frequent discharge measurements and daily gage-height observations. The discharge measurements are made through holes in the ice from 5 to 10 or even 20 ft. apart, depending upon the size of the stream, and large enough to allow the current meter to pass through freely.

The gagings are made in the same manner as at open sections except that the depth of the stream is taken as the distance from the bottom of the ice to the bed of the stream. The soundings, however, are always referred to the surface of the water in the holes, the distance from the surface of the water to the bottom of the ice being measured and subtracted from the soundings to obtain the depth.

The vertical velocity-curve method is usually used for the determination of the mean velocity in the vertical. A curve is plotted for each vertical, and the mean velocity is determined in the usual manner. These curves vary greatly as to form for different kinds and conditions of channel.

In using the meter, care must be taken to keep it under the water as much as possible to prevent ice from forming around the bearings. It is a good plan to clean and oil the meter indoors before starting out to make a gaging.

Gages and Gage Observations

The gage is usually read once each day, the observer noting the elevation of the water as it rises in a hole cut through the ice, the height of the top of the ice, the thickness of the ice, presence of needle or slush ice, snow on top of ice, ice jams, and any sudden changes in temperature. To do this, the observers are provided with an ice chisel for chopping holes, and an L-shaped ice scale to measure the thickness of the ice.

A difficulty which arises, in obtaining the thickness of the ice is that in a hole kept open for some time the ice wears away around the bottom of the hole, and may make it necessary to cut a new hole near-by, or enlarge the original.

Any form of gage may be used, but the chain gage is the most satisfactory, as the staff gage, being frozen to the ice, heaves with it, and also in cutting away the ice from around it the figures are effaced. The automatic gage gives trouble with the well freezing over.

Fig. 5. Ice Conditions at the Gaging Station on Spray River near Banff, Alberta. Taken on Mar. 5, 1912

Fig. 6. Ice Conditions at the Gaging Station on Kananaskis River near Kananaskis, Alberta. Taken Mar. 1, 1913

Estimates of Daily Discharge

While the runoff, particularly during the winter months, does not vary directly or coincidently with the precipitation, the rate at which it supplies the streams is, of course, dependent almost entirely upon the climatic conditions. The climate in the mountains is subject to great extremes, but during the winter almost the entire precipitation is in the form of snow.

There is, therefore, very little surface runoff and the flow of the streams comes almost entirely from the glaciers, groundwaters and lake storage, and except for the losses due to freezing and the slight increases due to the melting of snow and ice by chinooks (warm winds), the flow in the streams would remain constant or would change gradually.

There are, however, certain local conditions in Western Canada which make it exceptionally difficult to make estimates of the daily discharge during the winter. The gage heights in many cases fluctuate very much, and often sudden rises or drops occur. These rises are often

FIG. 7. ICE CONDITIONS AT THE REGULAR GAGING STATION ON BOW RIVER NEAR LAGGAN, ALBERTA DURING THE WINTER 1912-1913

FIG. 8. GAGING STATION ON BOW RIVER NEAR LAGGAN, ALBERTA, IN EARLY WINTER (NOTE THE SLUSH ICE FLOATING IN THE STREAM)

FIG. 9. ICE CONDITIONS AND GAGING TRENCH AT THE REGULAR GAGING STATION ON PIPESTONE RIVER NEAR LAGGAN, ALBERTA, ON FEB. 28, 1912

FIG. 10. MASS OF ICE IN DEVIL'S CREEK NEAR BANKHEAD, ALBERTA, CAUSED BY TURNING IN WATER DURING VERY COLD WEATHER

explained by the fact that during very cold spells a great deal of slush, frazil and anchor ice is formed and chokes up the channel, thus raising the surface of the water, when in reality the discharge is decreasing. Then, again, a chinook causes a sudden rise in temperature and the discharge is often increased while at the same time the gage height gradually lowers, evidently because the warmer weather and water have melted out a lot of the ice from

the channel and gives it a greater carrying capacity.

In order to make reliable estimates of the daily discharge, gagings must be made at short intervals and the weather conditions and temperatures in the whole of the drainage area above the station must be very carefully studied.

W. G. Hoyt, District Engineer, Water Resources Branch, U. S. Geological Survey, has made a very exhaustive study of methods for estimating the flow when streams are frozen. The various methods described by him in the article in ENGINEERING NEWS on Apr. 10, 1913, and modifications of them are used. The graphic method of interpolation has been found to be most generally applicable. But as the precipitation during the winter months has so little effect upon the runoff during that period, it is seldom plotted on the sheets. It is also considered that the extremes and ranges of temperatures are better guides for interpolation than the mean temperatures and the minimum and maximum temperatures are both plotted and given due consideration rather than the mean temperatures.

The weather conditions and temperatures at the gaging station are not always typical for the whole drainage basin above, and care must therefore be taken to have the meteorological observations made at some other place, or if necessary, at two or more places. Of course, care must be taken to study all the possible conditions which may affect the estimates.

Fig. 2 shows typical conditions and illustrates the graphic method of interpolating the daily discharges. The other views show conditions under which gagings are taken during the winter.

Rebuilding and Surfacing the Old National Pike with a Concrete Pavement*

The rebuilding of the old Cumberland or National Pike is of historical as well as engineering interest. The section which lies in Ohio will probably soon be improved throughout the whole length at an expense of about $2,000,000. A typical section, 24 miles long, between Zanesville and Hebron, is now under construction. It is being surfaced with concrete under joint appropriations of the U. S. Office of Public Roads, the counties of Licking and Muskingum, and the Ohio State Highway Department, at a cost of $436,017, including new bridges and culverts.

HISTORY OF THE OLD NATIONAL PIKE—The first appropriation of $30,000 for the Cumberland Road was made in 1806. This stretch extended from Cumberland, Md., to a point near Wheeling. Subsequent legislation for the Cumberland Road carried total appropriations amounting to $7,000,000, paid entirely out of the national treasury. These amounts seem small today, when the 1911 appropriations of states, counties and the national government total about $250,000,000, but they were large considering the scanty population and resources of the times.

The road was built by the Federal government, under the supervision of the War Department. The eastern end averaged in cost from $9000 to $13,000 per mile, which included heavy grading and massive stone bridges.

*Information from J. P. Beck, of the Universal Portland Cement Co., 208 South La Salle St., Chicago, which furnished the cement for the work.

FIG. 1. OLD NATIONAL PIKE OR CUMBERLAND ROAD EXTENDING ABOUT ONE HALF MILE EAST OF GRATIOT, OHIO

In eastern Ohio grading was much less and the cost was in the neighborhood of \$3500 per mile. Rivers and creeks were spanned by handsome stone bridges and culverts.

PRESENT CONDITION—The pike is still in fairly good condition when it is considered that practically no attention has been paid to its maintenance since it was turned over to the various states and later to the counties. Many of the original stone bridges are well preserved.

The class of houses along the Pike distinguish it from other roads. They are substantial, many being of

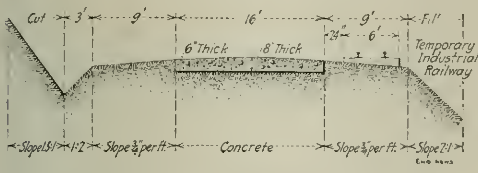

FIG. 2. TYPICAL CROSS-SECTION

stone. Some of the old inns, which were built at intervals of about 15 miles to serve travelers at the end of each day's travel, are still in existence.

NEW WORK—On. Apr. 15, 1914, the contract for the first section of new concrete pavement was awarded. Work was immediately started from both ends by grading gangs operating a traction engine, grader, rooter, roller, steam shovel and 50 teams. Bridge and culvert builders followed soon after, succeeded by gangs laying track along one side of the roadbed. As soon as trains were running, concrete mixers were put in operation.

The pavement is 16 ft. wide, 6 in. thick at the sides and 8 in. in the center and is laid on a flat subgrade. Expansion joints of tarred felt are placed 30 ft. apart at an angle of 75° with the center line.

Preliminary crowning of the concrete surface is done with a strike board made of three 1x6-in. boards bolted together. The lower edge is shaped to the desired crown, shod with a $\frac{3}{16}$-in. plate and additionally reinforced by two small angles. Long iron hooks fitting into eyes serve to move the board, which is held erect by means of ½-in. round steel handles. After the surface has been struck off two or three times it is brought to a still better crown by means of a template similar to, but lighter than, the strike board. Two men operate the template by lifting it a few inches, letting it fall and then moving it forward about 2 in. after each blow.

All curves over 12° are elevated on the outer edge to a maximum of 8 in. The superelevation is calculated for a speed of 30 mi. per hr. This elevation is accomplished by rotating the section of roadway about its horizontal center line so that the cross-section remains the same, the outer edges being elevated and lowered at the subgrade, respectively.

Steel forms are used and have proved very satisfactory. Three complete paving outfits are in operation. The mixers are of the boom and bucket type with batch capacities of 10 cu.ft. Although each crew of 35 men is rated as capable of laying 600 ft. in a day, there has been no time when all were working at maximum capacity so that the best day's run to date has been 1520 lin.ft. (for all the outfits). Wheeling to the mixer is done with a double set of barrows, one set being loaded while the other set is being wheeled and dumped into the mixer.

The contractor has had a private switch built from the railroad at each end of the road. The materials are unloaded to stock piles by clam-shell buckets from where they are loaded to elevated bins opposite. A 3-ft. gage industrial railway serves to haul materials. Cars are run under the hoppers and loaded as required.

A train, consisting of an engine, six cars, a second engine and two more cars, can be operated over a maximum grade of 5%. On steeper grades the last two cars are dropped, the two engines run up with the six cars and the last engine backs down and gets the two remaining cars. A complete train can be loaded in an average of 15 min. Cement is loaded by hand directly from the railroad cars to flat-cars on the industrial railway and hauled to site along with the other materials.

Very little difficulty has been encountered with cars jumping the track or with spreading rails. That the industrial railway has proved an economy is shown by the fact that the cost of hauling, 12c. per ton-mile, is about half the estimated cost of hauling by teams. As the length of haul increases the cost will be further reduced.

A railroad crosses the highway about two miles from the west end. This 2-mile stretch is being supplied with material by means of trains consisting of a traction engine and trailer cars. The cars are pulled into the railroad yard, loaded by clam-shell buckets directly from the stock pile and hauled to the site. The one tractor, hauling four or five 2-cu.yd. cars over this portion of the road, which is practically level, supplies all the materials for the single mixer.

Water for mixing and curing is supplied by pumping stations set at 4-mile intervals. These stations pump 2 miles in either direction through 2-in. mains. The sand and gravel are washed, screened and remixed to the proper gradations. At one end of the road gravel is used for coarse aggregate and at the other end crushed stone, the mixtures being 1 : 1½ : 3 and 1 : 1¾ : 3 for the gravel and crushed stone, respectively.

The federal government has three engineers on the work at all times, while the state has eight inspectors who hand in daily reports, which are compiled on cost-data sheets by the government engineers.

This is the largest and most thoroughly organized concrete road job that has ever been carried on by the Ohio State Highway Department and some valuable data will be available, it is anticipated, as the contractor is coöperating with the engineers in the compilation of all cost figures.

The contractor is the H. E. Culbertson Co., of Cleveland, with whom are associated Frank L. Shoemaker, contractor, and H. A. Johnston, and G. S. Allen, of the Globe Construction Co., all of Kalamazoo, Mich. C. H. Moorefield is the U. S. Office of Public Roads representative and R. N. Waid is Division Engineer for the Ohio State Highway Department.

A Damage Suit to Recover for a Poor Bituminous Pavement has been lost by the city of Hutchinson, Kan., because the city engineer failed to notify the pavement company of defects in the pavement. The company guaranteed the pavement for one year. The counsel for the defense argued that the contract stated that the pavement should be kept in good repair for one year, but that a statement had been inserted in the contract which made the city engineer solely responsible for the pavement. The city engineer neglected to notify the company of the defects which developed, and this, the counsel argued, excused the paving company from further liability. The case was decided in favor of the defendant by the United States court at Wichita, Kan., Oct. 1.

Formulas for Locating Frogs and Switches on Circular and Tangent Tracks

By [illegible]*

The [illegible] of turnouts from tracks [illegible] their curvature between switch and frog points is mostly by analytic methods, the solution being obtained after solving a number of triangles. Little information is to be found on the subject in standard handbooks, although the computations may be very much simplified through the use of worked-out formulas. With this end in view, the table on p. 928 has been prepared.

A variety of cases may arise, according to the features of the main track, the location of the turnout and the quantities to be solved for. However, provided the point to be located falls within a circular or tangent portion of the main track, any problem of this kind permits of a direct solution.

The following denominations will be used:

- P F = point of frog;
- P S = point of switch;
- P C C = point of compound or circular curve;
- P R C = point of reverse curve;
- P T C = point of transition curve;
- S, R = radius of main track;
- r = radius of turnout;
- g = standard gage;
- n = number of frog;
- F = angle of frog;
- J, K, L = angles of lead;
- l = lead on tangent.

Consider first the general case shown in Fig. 1, representing an inside turnout from a compound curve on the main track, the terms "inside" or "outside" being used in the following according as the frog is on the inside or outside rail of the main track.

The main track is here assumed to be composed of two circular portions with centers at i and c respectively. The position of the switch is supposed to be known, the radius through P S forming an angle K with the radius through P C C and intersecting the circle of radius $S + \frac{g}{2}$ at a point d. It is required to find the location of P F and the turnout radius corresponding to a frog angle F.

SOLUTION—Through center c, draw a line at an angle F with radius [illegible] and determine its point of intersection [illegible] with the circle of radius $R - \frac{g}{2}$. Draw a line through [illegible] and [illegible], producing it until it again intersects the circle [illegible]. A perpendicular bisecting line [illegible] at [illegible] will then intersect radius [illegible] at a point [illegible], which is the center of the turnout circle.

This is readily demonstrated by drawing lines [illegible] and [illegible]. [illegible] through [illegible] with [illegible] as a center must hit the [illegible] rail of the main curve at [illegible] and intersect the [illegible] rail at [illegible] at an angle [illegible] = F. [illegible]

[illegible] = [illegible], or, since [illegible] and [illegible], [illegible] = F, according to construction.

The circle [illegible] represents the outer rail of the turnout, P F being determined by the angle J between radius [illegible] and the radius through P C C.

To find the value of J, draw line bm perpendicular to cd. Since $\angle cfb = F$, we have:

$\angle dbm = \frac{1}{2} \angle dif = \frac{1}{2}(J + K + F)$. Further:

$$tan\ dbm = \frac{dm}{bm} = \frac{cd - ce \cos K - cb \cos F}{ce \sin K + cb \sin F}$$

Substituting

$$cd = S + \frac{g}{2};\ ce = S - R;\ cb = R - \frac{g}{2}$$

gives

$$tan\ \tfrac{1}{2}(J + F + K)$$

$$= \frac{S + \frac{g}{2} - (S - R)\cos K - \left(R - \frac{g}{2}\right)\cos F}{(S - R)\sin K + \left(R - \frac{g}{2}\right)\sin F} \qquad (1)$$

Considering that

$$tan\ \tfrac{1}{2}(J + F + K) = \frac{tan\frac{J}{2} + tan\frac{F + K}{2}}{1 - tan\frac{J}{2}\,tan\frac{F + K}{2}}$$

and that from the definition, $n = \frac{1}{2}\cot\frac{F}{2}$, we have by solving for $\frac{J}{2}$ and reducing

$$tan\frac{J}{2} = \frac{ng - S\tan\frac{K}{2}}{R + 2n\tan\frac{K}{2}\left(S - R + \frac{g}{2}\right)} \qquad (2)$$

By drawing line [illegible] and considering the triangles [illegible] and [illegible] we next obtain the following equations:

$$ie^2 = if^2 + ef^2 - 2\,if \cdot ef \cos F$$

$$ie^2 = ic^2 + ce^2 - 2\,ic \cdot ce \cos K$$

Substituting: $if = r + \frac{g}{2}$, $ef = R - \frac{g}{2}$, $ic = S - r$, $ce = S - R$, and substituting $\cos F = \frac{4n^2 - 1}{4n^2 + 1}$ and

$$\cos K = \frac{1 - tan^2\frac{K}{2}}{1 + tan^2\frac{K}{2}}$$

and reducing, we have:

$$r = S - \frac{\left[RS - 2gn^2\left(S - R + \frac{g}{2}\right)\right]\left(1 + tan^2\frac{K}{2}\right)}{(4gn^2 + R)\left(1 + tan^2\frac{K}{2}\right) + (S - R)(4n^2 + 1)\,tan^2\frac{K}{2}} \qquad (3)$$

In equations (2) and (3), J and r are expressed as functions of K. When, however, the location of P S is to be determined from a given P F, the problem is reversed and it is necessary to express K and r as functions of J.

By solving for K in equation (2), we have:

$$tan\frac{K}{2} = \frac{gn - R\tan\frac{J}{2}}{S + 2n\tan\frac{J}{2}\left(S - R + \frac{g}{2}\right)} \qquad (4)$$

*[illegible]

which value is substituted in equation (3). The expression thus obtained may be reduced to:

$$r = \frac{\left[R\left(S-R+\frac{g}{2}\right)\tan^2\frac{J}{2}+S\frac{g}{2}\right](4n^2+1)}{(2gn^2+R)\left(1+\tan^2\frac{J}{2}\right)+(S-R)\left(1+2n\tan\frac{J}{2}\right)^2} - \frac{g}{2} \qquad (5)$$

From equations (2) to (5), expressions covering all the various cases referred to at the outset may be easily derived, as will be shown through a few examples.

Considering the case of an *outside* turnout from the main track shown in Fig. 1, it is evident that, keeping the turnout in the same place, it will change to an outside turnout if the main track on both sides of P.C.C. is first straightened out and then curved the opposite way. In mathematical terms this is equivalent to reversing the signs of R and S.

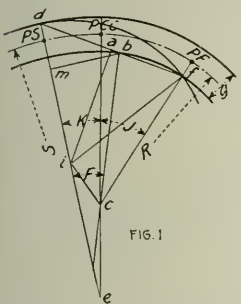

FIG. 1

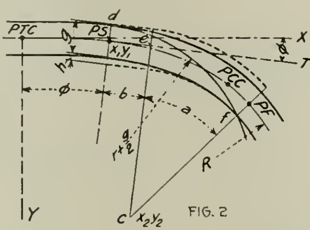

FIG. 2

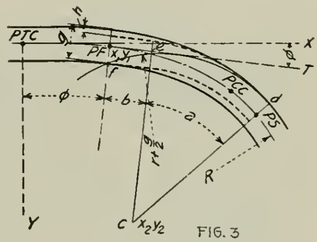

FIG. 3

The corresponding angles J and K, which may be expressed as inverse functions of their radii, would then have to be considered negative. It being more convenient, however, to deal with positive angles, we also reverse the signs of J and K, laying them off to the same sides of P.C.C. as before. If then, J or K comes out negative it is an indication that the frog number originally assumed cannot be used under the conditions given.

By substituting $-R$ and $-S$ for R and S in equations (2) to (5) and noting that $\tan(-x) = -\tan x$, we thus obtain the values for the case considered, as represented by the lower signs in the table. The turnout radius may, in this case, come out either positive or negative, a positive value indicating that at P.F. the turnout and main track are curved opposite ways, while for a negative r they are curved in the same direction (see left-hand and right-hand diagram, respectively).

Similar reasonings are applied in deriving the formulas for a main track made up of two circular portions of reversed curvature: For inside turnouts, reverse the signs of S and K in equations (2) to (5); for outside turnouts, reverse the signs of R and J. In this case, only positive values of r need be considered.

If the main track is made up of one circular and one tangent portion, the value ∞ will have to be substituted for R or S in equations (2) to (5), according as the frog or the switch lies on the tangent portion.

When P.F. is on a tangent, the substitution of $R = \infty$ will make both sides of equation (2) zero, as angle J may be expressed as $\frac{d}{R}$, where d represents the subtended arc as measured along the center line of track. To obtain a definite equation, multiply both sides of equation (2) by $2R$:

$$2R\tan\frac{J}{2} = \frac{2R\left[ng - S\tan\frac{K}{2}\right]}{R + 2n\tan\frac{K}{2}\left[S - R + \frac{g}{2}\right]}$$

Substituting $\frac{d}{R}$ for J, we then have for left and right side respectively:

$$\left(\lim_{R=\infty}\right)\left[2R\tan\frac{d}{2R}\right] = \left[\lim_{\frac{1}{2R}=0}\right]\left[\tan\frac{d}{2R} \div \frac{1}{2R}\right]$$

$$= \left[\lim_{\frac{1}{2R}=0}\right]\left(\frac{d}{\cos^2\frac{d}{2R}} \div 1\right) = d \qquad (6)$$

$$\left(\lim_{R=\infty}\right)\frac{2R\left[ng - S\tan\frac{K}{2}\right]}{R+2n\tan\frac{K}{2}\left[S-R+\frac{g}{2}\right]} = \frac{2\left[gn - S\tan\frac{K}{2}\right]}{1+2n\tan\frac{K}{2}}$$

The limits of equations (3) to (5) are found by simple differentiation, the value of $R\tan\frac{J}{2}$, as found in equation (6) being substituted where convenient.

Similarly, when P.S. is on a tangent, multiply both sides of eq. (4) by $2S$. By substituting $K = \frac{d}{S}$ and differentiating we have:

$$\left(\lim_{S=\infty}\right)\left[2S\tan\frac{d}{2S}\right] = d$$

the other three expressions being obtained from equations (2), (3) and (5) through plain differentiation.

The formulas thus derived apply to inside turnouts. To obtain the corresponding expressions for outside turnouts, simply reverse in each formula the sign of the main track radius (R or S) and the corresponding angle (J or K). Where there is only one main track radius to be considered in the final formulas, this radius has, in the table, been designated by the letter R while for the angle of lead the letter L has been used.

Coming finally to the cases where there are several changes in the curvature of the main track between P.F. and P.S., a typical example of this kind is shown in Fig. 2, representing an inside turnout df (only the outer

FORMULAS FOR LOCATING FROG AND SWITCH POINTS ON CIRCULAR AND TRANSITION TRACKS; DEVISED BY ARTHUR BELL

rail shown), having its switch on a transition and its frog on a circular curve, it being required to locate P.F.

A tangent T is drawn to the center line in P.S. and from the center of the circular curve a perpendicular ce to this tangent. The main track is thereupon replaced by the one shown by dotted lines, consisting of a tangent portion b, parallel to the tangent T, and a circular portion a, concentric with the circular main track curve and having an outer and inner rail radius of $ce + \frac{g}{2}$ and $R - \frac{g}{2}$ respectively. Since this change will not affect the position and curvature of the rails intersecting at the frog (f), the problem is reduced to one of those previously considered.

Applying the formulas for an inside turnout having its frog on a circular curve and its switch on a tangent, it should be noted that the gage of the dotted track is wider than the standard by an amount

$$h = ce - R$$

Substituting in equations (1) and (3) in the table, for g, the value $g + h$, and for R, r and d, the corresponding values $R + \frac{h}{2}$, $r - \frac{h}{2}$ and b, we obtain the formulas for the case in question by a simple reduction.

Fig. 3 represents an inside turnout fd, having its frog on a transition and its switch on a circular curve, it being required to locate P.S. By drawing a tangent T to the center line in P.F. and a perpendicular ce, we find in a similar way that by substituting for the original track the one shown by dotted lines, we may apply the formulas for an inside turnout having its frog on a tangent and its switch on a circular curve, the quantities to be substituted for g, R, r and d being, in this case, $g - h$, $R + \frac{h}{2}$, $r + \frac{h}{2}$ and b, h having the same value as above.

The corresponding formulas for outside turnouts have been derived in a similar way.

As to the quantities h and b, they may be considered as the rectangular coördinates of the center c, referred to the given point as origin and the tangent T as X-axis. Knowing the coördinates of the center (x_2, y_2) and the given point (x_1, y_1) in any other rectangular system, we therefore have:

$$h = (y_2 - y_1) \cos \phi = (x_2 - x_1) \sin \phi - R$$

$$b = (x_2 - x_1) \cos \phi + (y_2 - y_1) \sin \phi$$

Where angle ϕ is the slope angle of the center line at the given point.

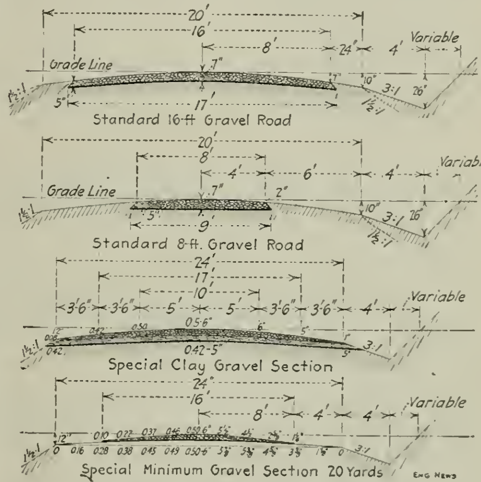
When, as in the above examples, the lead is partly on a transition, P.T.C. is conveniently chosen for origin.

Gravel Roads in Minnesota

In Minnesota, most of the road surfacing is being done with gravel. The specifications are varied to suit local conditions, as the roads are built on all kinds of soil and the quality of gravel must vary accordingly. It is very difficult to secure gravel that is properly graded for road making, and the engineers of the State Highway Commission usually consider themselves fortunate if appropriations can be secured sufficient to haul gravel from available pits without going to extra expense for screening and remixing or grading.

The standard sections for gravel roads with paved widths of 8 ft. and 16 ft. are shown in the accompanying cut. There is shown also a special 16-ft. section which has been adopted; this requires 20 cu.yd. per station, and has proved very satisfactory where sufficient funds are not available for the standard 16-ft. roadway. The clay and gravel section shown in the cut has been adopted for sandy locations where adequate funds for standard construction cannot be obtained.

The 8-ft. width is not considered advisable as a rule, for the maintenance by dragging tends to mix the shoulder material with the gravel, and the turning out of vehicles on this narrow roadway also breaks down the edges so that the gravel is soon lost. It is considered that two applications of the special 20-cu.yd. section would be more satisfactory on heavy-traffic roads which must be built at low cost. The specifications provide that



STANDARD AND SPECIAL ROAD CROSS-SECTIONS ADOPTED BY THE STATE HIGHWAY COMMISSION OF MINNESOTA

when the 8-ft. gravel road is built on heavy soil it is advisable to place a 2-in. layer of gravel for a width of 4 ft. on each shoulder, thus protecting the edges of the roadway proper.

These two special sections, therefore, represent a compromise practice designed to meet conditions where the financial factor is the governing factor as to road improvement. They indicate very strongly the attention which highway engineers are giving to local conditions, to enable good roads to be made at a minimum cost where necessary, both by the use of local materials and by adapting the improvement work to the funds available. This practice undoubtedly increases the popularity of state-aid in road improvement, and is calculated to offset the deep-seated popular suspicion that state authorities in charge of roads will seek to build them in an expensive manner.

The roadbed is graded to the sections shown and the 9-ft. or 17-ft. base is well rolled or otherwise compacted. When the fill is over 5 ft. high, the roadbed width is made 24 ft., with a crown or rise of 12 in. It must be free from ruts and waves or undulations, and gravel must not be deposited upon a wet or muddy roadbed. The gravel must be deposited to rope lines set out at the proper

distance from the center lines, and the specifications provide that the gravel must be shoveled into place and not dumped on the road in such a manner as to develop a wavy surface after settlement. Even when the wagon loads dumped on the road are carefully leveled there is very apt to be greater density at the dumping place, which eventually results in the wavy surface referred to.

In general, the gravel is measured in the wagon boxes as delivered on the work, and checks showing the amount in each load are furnished to the driver by the inspector in the employ of the county.

The gravel is furnished by the county, but is required to be approved by the engineer as to its quality. It must be free from [illegible] and from stones over 2 in. in diameter, while stones over 1 in. diameter must be kept at least 4 in. below the finished surface. The gravel must not contain more than 10% of sand and 15% of clay, but these limiting proportions may be altered at the direction of the engineer in the surfacing of heavy clay roads or sandy roads. When a clay base is required (section C) it must be deposited in advance of the gravel, distributed to uniform width and thickness, and either rolled with a 5-ton roller or dressed with road machine and road drag.

The gravel is finished to a firm and even compact surface, either by means of a roller (not less than 5 tons) or by a system of maintenance by means of dragging and raking for at least 30 days after completion. If for any reason rolling is not done, the work will not be accepted until three months after the gravel is placed, or until it has settled to a permanent base, and the contractor will be required to keep it raked smooth and in good condition until it is accepted by the engineer. This maintenance by the contractor is necessary, of course, to prevent traffic from wearing ruts and holes in the loose gravel.

After the gravel has been thoroughly compacted, the earth shoulder is finished to the section shown, and the whole roadway then rolled or dressed with a road machine and drag.

George W. Cooley is State Highway Engineer and John H. Mullen is Chief Deputy State Engineer. The offices of the State Highway Commission are at St. Paul, Minn.

Concrete Viaduct with 50-ft. Walls

SYNOPSIS—The viaduct carrying Union Ave. over the tracks of the St. Louis (Mo.) Terminal R.R. is mainly a fill between retaining walls, which are of the semi-gravity type and have a maximum height of nearly 50-ft. The tracks are crossed by three slab and girder spans forming a single continuous-girder structure.

One of the works for the elimination of grade crossings at St. Louis is the construction of a viaduct 1190 ft. long carrying Union Ave. over the tracks of the St. Louis Terminal Ry., in the northwestern portion of the city. The line is in a cut in a valley and the track grade conforms somewhat, the viaduct having opposite grades of about [illegible] to attain the required elevation. It is [illegible] ft. wide over the roadway, with a 30-ft. roadway, the sidewalks and parapet walls taking up the remaining [illegible] ft.

The general design is shown in Fig. 1. The structure has three reinforced-concrete spans (of the slab-and-beam type) over the right-of-way, the central span [illegible] ft. c. to c. of piers and the side spans [illegible] ft. For the remainder of its length it is a solid fill between concrete retaining walls. There are only two tracks at present, but there will be additional tracks forming the entrance to a new freight yard. The viaduct was built at the expense of the railroad company.

Design of Retaining-Walls

The special feature of interest is the height of the retaining-walls of the fill. At one point, north of the tracks, the line of the viaduct crosses the bed of an old creek, partly filled in, the flow of the creek being diverted by a pair of cast-iron culvert pipes into a new concrete sewer. This sewer runs under the eastern side of the viaduct for a part of the distance and then makes a turn, crossing under the east wall, as shown. Concrete is filled between the crown of the sewer and the bottom of the wall, and extra heavy reinforcing is used in the bottom of the wall at this point.

For about [illegible] ft. at this creek bed, it was considered necessary to carry the walls to rock, and here they have a maximum height of about 50 ft. The foundations elsewhere are on the bed of yellow clay above the rock, and no piles have been used. Typical sections are shown in Fig. 2, and at some points there is beneath the bottom a [illegible] 3 ft. wide and 2 ft. deep.

The walls are of semi-gravity section throughout, and have steel reinforcement in the bottom and inner face, while additional reinforcement is used in the bottom of the east wall where it crosses the sewer. They were designed in accordance with Rankine's theory of earth

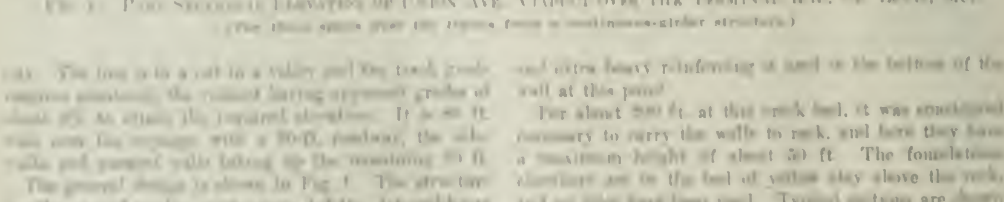


Fig. 1. Part Sectional Elevation of Union Ave. Viaduct over the Terminal R.R., St. Louis, Mo.
(The three spans over the tracks form a continuous-girder structure.)

pressures; the weight of concrete was assumed as 144 lb. per cu.ft., and that of the earth fill at 110 lb., with a surcharge of 1 ft. allowed for live-loads on the fill.

The walls are in 30-ft. lengths, with expansion joints, as shown. The face of the wall is relieved by the pilasters which mask these joints, while the flat surface in each 30-ft. length is relieved by a slightly depressed panel outlined by a broad depression 18 in. wide. The effect is carried out also in the abutments, the track face of each having one large panel. Each section of the wall has two weep-holes of 4-in. vitrified pipe, placed at the elevation of the future fill against the outer side, and having loose stone piled around the inner end.

The parapet wall is of ornamental pattern with a series of vertical openings. This parapet, with its pedestals, was cast in place after the construction of the walls. Gas lamps will be erected on the pedestals. A rather unusual feature in the construction of this viaduct was the placing of its "cornerstone" with some civic ceremonies. The "stone" is the base of one of the end pedestals, of the parapet, and in this was embedded a bronze box containing coins and newspapers. Some trouble was experienced in finding room for the box between the reinforcing rods.

Reinforced-Concrete Bridge Spans

The three spans over the railway are of the slab-and-girder type, with 14 ribs or girders. The facia girders are 17 in. wide and 52½ in. deep over all, and the inner girders are 23 in. wide and 40 in. deep (including the 7-in. deck slab). The four middle ribs come directly under the rails of the street-car tracks. The design is shown in Fig. 3.

The three spans form one continuous structure, the girders being anchored to the piers and having expansion bearings on the abutments. At each end there is an expansion joint between the slab and the face of the back wall of the abutment. In this is inserted a U-shaped strip of copper which is filled with asphalt. Above this is a filling of tar-paper separating the concrete foundation for the paving on the spans and approaches. The ends of the girders have steel shoe plates embedded and anchored in the concrete, and these rest on steel bearing-plates anchored to the bridge seat of the abutment, as shown. These plates are milled, and are coated with tallow on the contact faces.

Upon the deck slab was laid a course of concrete forming the foundation of the paving, 8½ in. thick at the center and shaped to the proper contour. In this were embedded the ties for the street-railway tracks, and upon it was placed a 1-in. sand cushion for the 3½-in. wood-block paving. The sidewalks have a similar concrete base

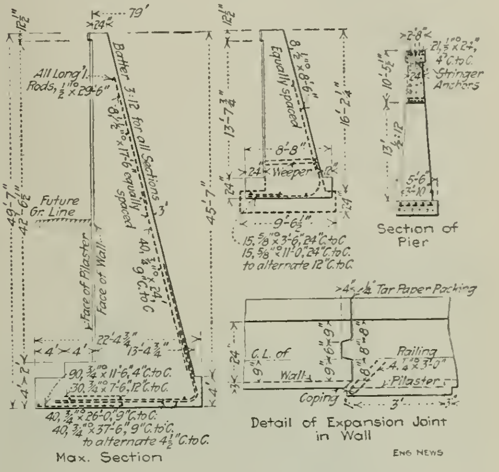

Fig. 2. Sections of Retaining Walls and Piers of Union Ave. Viaduct, St. Louis, Mo.

(The walls are of the semi-gravity type and have a maximum height of nearly 50 ft.)

with a 1-in. top finish. The curbs are of granite, with an asphalt expansion joint between each curb and the wood paving.

The piers are of the section shown in Fig. 2, and each is pierced with three arched openings 4 ft. wide to reduce the weight. They were built with rods projecting from the top to form anchors for the continuous stringers. The abutments are similar to the retaining walls, but with a ledge for the bridge seat and a back wall above this to retain the fill of the approach.

The spans were designed under the following conditions as to live-loads and stresses: (1) Track stringers: two

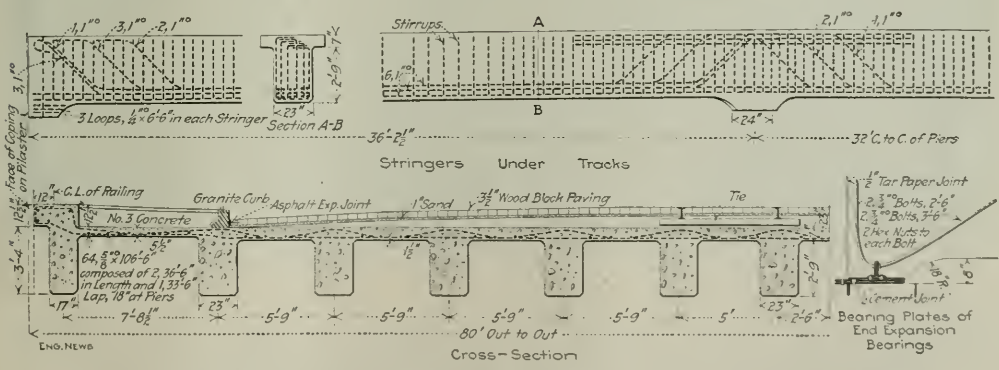

Fig. 3. Track Spans of the Union Ave. Viaduct over the Terminal R.R., St. Louis, Mo.

[illegible] type, having trucks of 11½-ft. wheelbase, 30 ft. c. to c. of trucks, and loaded with 13,800 lb. per wheel. (2) Roadway stringers, an 18-ton road roller, with 6 tons on the roller and each wheel (11-ft. wheelbase, 5 ft. c. to c. of wheels). (3) Roadway slab, a concentrated load of 8 tons on an area 1×1 ft., and a uniformly distributed load of 150 lb. per sq.ft. (4) Sidewalk slab, uniformly distributed load of 100 lb. (5) Impact allowance, 30% on slabs, 10% and 20% on stringers (under and over 25 ft. long). (6) Maximum fiber stresses for concrete, 650 lb. per sq.in. for compression (cross bending), 45 lb. per sq.in. for shear without shear reinforcement, 125 lb. per sq.in. for total shear on section, steel to carry all diagonal tension. (7) Maximum fiber-stresses for steel, 16,000 lb. per sq.in. tension, for cross bending and for shear reinforcement, 100 lb. for the adhesion of deformed bars.

Construction Work

During the construction of the viaduct this section of [illegible] Ave. was closed, being in an outlying section, and traffic was diverted while passengers on the street cars had to walk around the work, using the grade crossing at the next street.

Concrete material was delivered in cars on a siding, and unloaded into stock piles by a stiffleg derrick mounted (with its engine and boiler) on a tower or platform some 15 ft. high. The same derrick and clam-shell bucket handled the material from the stock piles to the storage bins over the 1-yd. concrete-mixing plant, which was located just east of the structure and on the north side of the tracks.

The concrete was discharged into 1-yd. drop-bottom buckets, the bucket standing on a small narrow-gage flat car, [illegible] being put on the ends of the car to support the sides of the bucket and carry its drop-bottom doors clear of the car floor. The cars were then moved a short distance on the track (transverse to the center line of the bridge) and stopped under the cableway used to convey the concrete along the line of the walls. The bucket was then raised, run to the desired point over the retaining wall and dumped into the forms.

The cableway was 600 ft. long, with an 80-ft. tower at the [illegible] end and a single bent 60 ft. high at the [illegible] end. It was placed over each wall in turn, and was shifted laterally 80 ft. from one wall to the other without being dismantled; this was done by placing [illegible] under the towers. Handling the 12,500 yd. of concrete by cableway was economical, as the amount of concrete at the ends of the walls is small, and wheeling it so far would have been slow and expensive.

The walls were poured in alternate 30-ft. sections to allow for contraction, and 2-ply tar-paper was used to fill the joints. The wall forms were built continuously from the footing to the coping of 2-in. sheeting [illegible] and held by [illegible] ¾-in. [illegible] spaced [illegible] in. apart vertically. This proved ample for the rate of filling, which was arranged not to exceed 2 ft. vertically per hour during temperatures from [illegible] to [illegible] F. During the cold spell of [illegible] to [illegible] F. [illegible] the concrete being [illegible] as it [illegible] the [illegible] and [illegible] the heads of the [illegible] in the forms [illegible] the aggregate away from the exposed faces. [illegible] were used with [illegible] lb. weights [illegible] below them. These [illegible] had been [illegible] and were set by the cableway, being

[illegible] moved readily where needed. The bucket discharged into the tray.

A crew of 2 engineermen (75c. per hr.), 8 concreters (30c.), 2 laborers (20c.), and a foreman (62c.), sufficed to unload the materials and put the concrete into the walls. The plant charge was about $10,000. The total price for concrete in place (exclusive of cement furnished by the railway company) but including the forms, was $4.85 per cu.yd. For the walls, the batches averaged 0.9 cu.yd. and 175 to 220 batches were mixed daily. During midwinter, 1212 yd. were placed in the northwest wall in 14 consecutive working days of 8 hr. each.

The concrete was made with 1½-in. washed gravel as the coarse aggregate. It was 1:2½:5 for the retaining-walls, piers, and abutments, 1:2:4 for the girders and deck slab, and 1:4:8 for the paving foundation. For the railings or parapet walls, the aggregate was ¾-in. binder gravel and washed river sand. The walls were completed to the coping at the sidewalk level, the pedestals and panels of the parapets being built later. In this parapet, some trouble was found in placing the reinforcing steel within the small space of the completed forms. This was overcome by building the forms with the inner side omitted, so that the interior was open for placing the steel properly, after which the side was put on and secured.

The exposed surfaces of the walls were wetted and rubbed down with concrete blocks to remove form projections, etc., and were given a wash of 1:1 grout to secure uniformity of color. The parapet railing was not given any finishing treatment.

The bridge spans had to be built without interfering with the traffic on the railway below, which amounts to about ten trains daily. The three spans were poured together, the forms being supported on framed bents between the tracks. For this part of the work ([illegible] yd.) the concrete was distributed by a chute from the head tower of the cableway.

The earth fill between the retaining walls was deposited by dump wagons, the material being taken from widening along the top of the railway cut, adjacent to the viaduct. Over this was [illegible] an elevating grader hauled by a steam tractor, loading the earth directly onto wagons moving beside the grader.

It was anticipated that there might be trouble with water in building the work through the old creek bed, as when the sewer was built (1911) a freshet washed out the forms and temporary work and caused considerable damage and expense. But the season of 1913 was dry and no trouble was experienced.

Engineers and Contractors

The structure was designed and built under the direction of the St. Louis Terminal Ry. Co., H. J. Pfeifer, Engineer of Maintenance-of-Way, and A. E. Anderson, Resident Engineer in charge. Bledsoe & Fay, of St. Louis, were consulting engineers. The work was done by the Fruin-Colnon Contracting Co., of St. Louis, and was in charge of A. P. Greensfelder, Secretary and General Superintendent for the Company. The contract was let in July, 1913, and the work was completed in July, 1914. The contract price was about $115,000, exclusive of the paving of the approaches. The cement was furnished to the contractor by the railway company.

Portable Plant for Asphaltic-Concrete Roads in Chicago

The work of improving main lines of road in the outskirts of Chicago, in order to connect the country roads with the paved streets, was inaugurated in 1913 and was described in ENGINEERING NEWS of Jan. 1 and Sept. 10, 1914. These roads were built of macadam and coated with oil. The amount of maintenance work required has been very high, due partly to the low and wet land, and partly to the tendency of traffic to follow ruts in a road only 18 ft. wide. To eliminate this condition of rapid wear and excessive maintenance, it was decided to cut down the crown and resurface the roads with a 2-in. top of asphaltic concrete.

For this work, under the direction of the Bureau of Streets, a portable plant was purchased, at a cost of $13,000, having all the equipment complete on one railway car. The car is moved from place to place at the outskirts of the city and at each site it is placed on a central track, with a track on one side for the cement car and one on the other side for the oil-tank car, as shown in Fig. 1. The tracks are 16 ft. c. to c. The oil is heated in the tank and pumped to the mixer. The plant with all apparatus folded up for transportation resembles a large furniture car and weighs about 20 tons.

The sand and stone are proportioned and mixed on the ground, and delivered by a bucket conveyor to the dryer, where the material is heated to about 300 ° F. From the dryer it goes to the storage bins, and is drawn off to the measuring bin and the mixer, which is of 15 cu.ft. capacity. Coal or oil fuel may be used, but the latter is employed at present.

For conveying the asphaltic concrete from the plant to the road the city has 20 dump wagons, the number in use depending upon the length of haul. There are also two 5-ton motor trucks, each doing the work of three teams. The average haul is about two miles, with a maximum of five miles. The rolling is done with 10-ton rollers.

The asphalt plant has been turning out 2500 sq.yd. of 2-in. top per day, or 1000 lin.ft. of 18-ft. roadway in nine hours. The Bureau is completing a mile each week at a cost of about 70c. per sq.yd. This includes all cost of preparing the old road and laying the new top. This improvement is expected to last five years without repair, and the maintenance will then be slight in comparison to the old water-bound macadam. It is desirable to have at least 10 in. of stone at the center and 4 to 6 in. at the edges, so that in some cases 3 to 4 in. of new material is laid on the road before resurfacing. The surface is made as flat as possible.

The mix averages approximately 6.5% bitumen, 37.2% sand, 52.3% stone, 1% filler. The aggregate is crushed granite (1/4 to 1 in.), with torpedo sand and portland cement. The price of granite this year is $2.25 per cu. yd. With the plant running at full capacity, the force at the plant and on the street is composed as shown in the accompanying table.

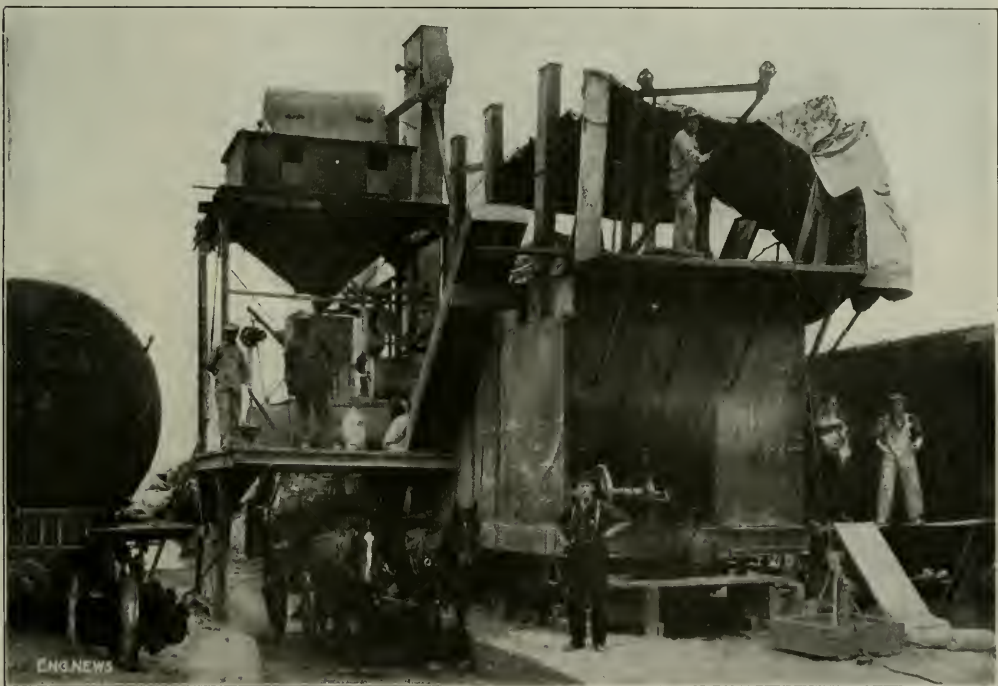

FIG. 1. PORTABLE PLANT FOR MAKING ASPHALTIC-CONCRETE FOR SURFACING MACADAM ROADS ENTERING CHICAGO

[illegible] FOR ASPHALTIC-CONCRETE ROAD WORK

At the Plant		On the Road	
[illegible]	[illegible]	1	[illegible]

[illegible]	[illegible]		
[illegible]	[illegible]		
1	[illegible]		
2	[illegible]		

The work of preparing the old macadam road varies. Where the existing surface is in good condition and has suitable line, grade and contour, the surface is swept

FIG. 2 IMPROVING COUNTRY ROADS WITHIN THE CITY LIMITS OF CHICAGO

(The view at the left shows the 2-in. top course of asphaltic concrete being laid and rolled. The view on the right shows the old road receiving a course of [illegible] to level it up for the asphaltic-concrete top course.)

thoroughly to remove all the loose particles and expose the rough stone. Any depressions are filled with binder and tamped; in this way the existing road is made parallel with and 2 in. below the finished surface. Along the edges of the road care is taken to provide a good shoulder to hold the pavement in place. Where the soil is soft, [illegible] added and the shoulder rolled.

Where the old macadam is flat or depressed at the center, the sides are picked up and the material moved to the center. Care is taken not to loosen the sides so that there will be less than [illegible] in. of stone in a firm condition. Where the condition is such that additional material is required, the street is scarified to a depth of [illegible] in. and material added to make the depth at least [illegible] in. at the middle and [illegible] in. at the sides. About [illegible] in. fall from the crown to the side is sufficient for drainage.

This work is paid for out of the [illegible], which is imposed on [illegible] for the purpose of providing a fund for road repairing. The description given above is compiled from information furnished by Walter [illegible], [illegible], Superintendent of Streets of Chicago.

Headquarters Inspection Division of the New York State Highway Department

The many difficulties which were experienced in connection with the final inspection and acceptance of roads after they had been completed by the contractor have led George A. [illegible], First Deputy State Highway Commissioner of New York, to devise and install a new method of inspection by a headquarters outpost inspection, which has proved efficient and beneficial in all respects. The function of these inspectors is almost entirely critical; they give no orders and are warned from about offering advice unless it is asked for by the engineers in charge of the roads which they are inspecting. They are all high-class, experienced and well paid engineers.

Mr. [illegible]'s scheme consists in having a number of these inspecting engineers, reporting to and solely responsible to him, continually engaged from the beginning to the end of the working season in making field inspections. There are seven of these inspectors for the [illegible] highway divisions of the state. Each inspector makes the rounds of his territory in about 20 days, coming and reporting upon every piece of construction work during that period. They report regularly the extent and character of the work done to date not only by the contractors but by the state's engineers.

After studying these reports, the Deputy Highway Commissioner takes up with the division engineers any points which may be necessary. These points of criticism are communicated by the division engineers to the engineers in immediate charge of the work in a [illegible] form letter, with a request for explanations and constructive criticism. The reply is made on the back of this letter, and this and the inspector's report are fastened together and filed.

As noted, there is a report on each road on an average of once in 20 days. When the contracts are completed the headquarters office thus contains a complete and detailed history of each road, with complete information regarding it and [illegible] report of surface conditions after the road is completed. This not only greatly facilitates final acceptance of the road from the contractor, but [illegible] or [illegible] out at the time they are made, mistakes and deviations from the contract specifications which would [illegible] final settlement.

Although not at first looked upon with approbation by the contractors, this system of inspection was proved of so much value to them and division engineers as well as to the First Deputy Commissioner, who is [illegible] by the chief engineer of the highway department, that it is now recognized as a very useful and satisfactory adjunct of the department. The scheme has passed the experimental stage and is a regular feature of the organization.

Reconstruction of Pogues Run at Indianapolis

A costly piece of sewer work which has just been commenced at Indianapolis, and is an important preliminary to the extension of track elevation through the union station, is the reconstruction of the Pogues Run drain for a distance of about 2½ miles. This is an old creek now forming an open sewer, which flows approximately southwest across the city and discharges into White River. Its normal dry-weather flow is about 5 cu.ft. per sec., but in times of freshets and heavy rains it may have a flow of 3000 cu.ft. per sec.

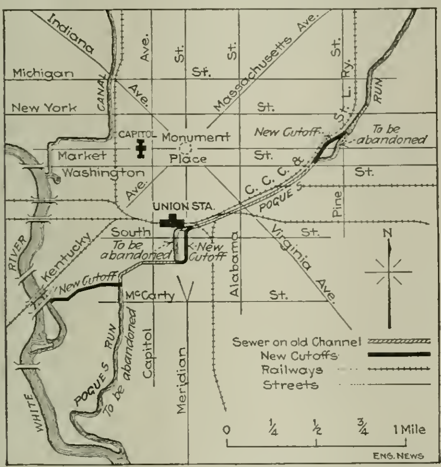

FIG. 1. PLAN OF THE NEW COVERED CHANNEL FOR POGUES RUN AT INDIANAPOLIS, IND.

For a length of about 5100 ft. through the railway yards and terminals the creek is lined with masonry walls 36 ft. apart, and is spanned at some points by plate-girders which carry signal cabins and similar structures. The creek closely follows one of the railway lines and as it crosses the site of the union station and terminal yards the city must replace the present open channel by a covered channel. This will mainly follow the present route, but between New York and Washington St., a bend will be avoided, and near the station there will be a new line along Meridian St. There will be also a new outfall, giving a direct line to the river instead of the present winding course. These diversions are shown on the map, Fig. 1.

The grade in general is 0.15% and 0.20%, but there is a short fall of 0.5% from Washington St., while at the outfall the grade is 0.7%. The sharpest curves are of 100-ft. radius. Beyond the portal will be a 30-in. reinforced-concrete apron on piles, with wing walls. This will be 25 ft. long, with a width (between wing walls) of 39 ft. 2 in. at the portal and 51 ft. 2 in. at the lower end.

The new conduit will be of reinforced concrete, and will be of very exceptional size and construction, consisting of two rectangular channels, as shown by the typical section, Fig. 2. At the upper end these will be 16 ft. wide and 8 ft. high, but mainly they will be 18x8 ft., while for a portion of the lower end and at the portal the width is increased to 19 ft. The two channels are to be connected at intervals of 100 ft. by openings 6x5 ft. in the center wall. The depth of fill over the roof will be from 4 to 20 ft., and at some points the conduit walls will have to carry the columns of street bridges (over the tracks) and of the station structures.

The side walls will be 18 and 20 in. thick and the central wall 18 in. The top and bottom slabs are mainly 21 to 24 in. thick, but at certain points these are increased to 32 in. for the top and 30 for the bottom.

The arrangement of the reinforcing steel is shown in Fig. 2. It will consist of deformed bars. In construction, the bottom and walls will be built first, and then the roof, with a mortised joint along the tops of the side walls, as shown. The concrete will be 1 : 2½ : 5 for the lower portion and 1 : 2 : 4 for the top, using gravel for the aggregate. The construction will be attended with some difficulty, especially where the drain passes under the tracks and adjacent to large buildings, which will have to be shored up while the foundations are being underpinned.

This work was approved by the Board of Public Works in April, and in June the contract was let to Dunn & McCarthy, of Chicago, at $907,000. In addition to this cost, there will be the expense of supporting buildings during construction, and this is estimated to cost about $31,000. The work is under the direction of B. J. T. Jeup, City Engineer, and D. C. Hayne, Assistant Engineer.

Field and Office

Construction Plant Layout for New Filtration Plant at Cleveland, Ohio

Work on the new filtration plant for the Cleveland waterworks system, which is to be located near the lake front between West 29th St. and West 38th St., is progressing very rapidly. The exceptional speed with which the work is being done is due in no little degree to the very well laid-out construction plant which the contractor, John F. Casey Co., has installed and is operating.

Fig. 1. Plan and Section of Construction Plant at New Filtration Plant at Cleveland, O.

The filter plant is on what was a side hill running down in about 500 ft. from an elevation of 90 ft. to an elevation of only 8 ft. above lake level at the north or lake side of the site. The dimensions are 1200 ft. running east and west parallel to the lake and 700 ft. north and south. Previous to the letting of the contract, the city arranged to cut the grade most of the area covered by the various basins of the plant and turned the site over to the contractor in this shape, except for one section at the southeast end of the plant where extensive steam-shovel excavations had to be made later.

The topography of the site lent itself admirably to the cableway installations shown in Fig. 1. Briefly, the layout consists of a concrete-mixing plant accessible from main-line railroad sidings and dumping over narrow-gage tracks running out under two cableway spans, the towers of which travel parallel to the long dimension of the filtration plant and control the narrow-gage track and a main-line siding, and the entire field of construction operations.

The method of carrying on the work can be traced to better advantage by examination of the plan in Fig. 1. The tracks of the Erie R.R. enter the fenced-in site from the northeast. Sand and gravel are brought in on a siding from the main line and carried up on the trestle and dumped into open bins just north of the concrete mixer. From these open bins the gravel and sand are lifted by a locomotive crane traveling on the trestle into storage bins in the top story of the mixing plant. Cement is brought in over the same track and is normally delivered in such quantity that the cement can be loaded directly from the cars in sacks onto the belt conveyor, which is shown leading into the mixing plant where it is stored on the same floor as the top mixing hopper. When a surplus of cement arrives, it is stored in the cement shed shown just east of the mixing plant. All other material is brought in on the main-line track just south of the cement track and is stored in various parts of the yard where convenient.

A mill is placed just near the stub end of this track and another track runs around to the north of the mixing plant, so that it is convenient to the machine shop located there. The cableway tracks, each consisting of three rails to carry the usual pyramidal tower, run in an easterly and westerly direction, one on the lower level north of the work and the other on the upper level, some 90 ft. higher along the top of the original bank and entirely south of the work. The head tower is 74 ft. high and the tail tower 85 ft. high, while the span is 700 ft. There are two cableways provided, each of a capacity of 15 tons and each with its own hoisting-engine equipment. Another main-line stub end runs directly under the cableway span, by which material can be picked directly off the main-line cars and conveyed to whatever part of the work it is required.

For concreting there is a duplicate equipment of Hains mixers of a design improved by Ottmar Stange, a member of the contracting firm which is doing the work, but so far it has been necessary to use only one of the mixers to take care of all the concreting which has been needed. The Hains mixer is of the gravity type, which requires no power. It consists of a series of approximately conical buckets placed one above the other, into the top one of which the various ingredients making up the concrete are dumped and receive the mixing action by tumbling over through the series. As shown in Fig. 3, the sand and

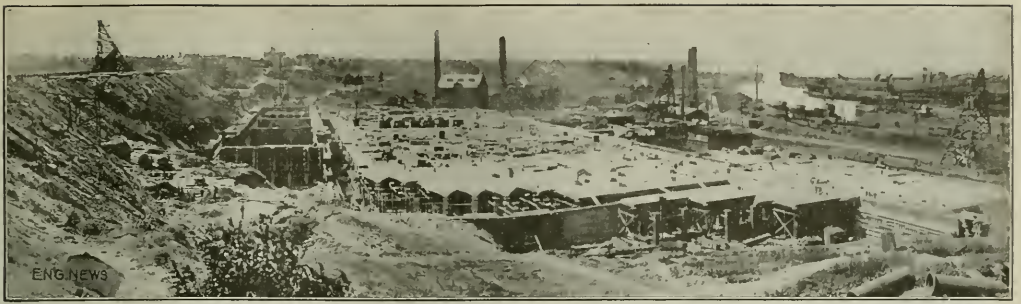

FIG. 2. LOOKING SOUTHWESTERLY OVER CONSTRUCTION PLANT AT CLEVELAND FILTRATION PLANT
(Upper cableway tower on left; lower towers on right. Concrete plant in background.)

gravel are stored on the top floor of the mixer house and can be dumped into the top hopper by merely throwing a gate. Proper measurement is made by marks on the side of the top hopper bucket, which can accommodate about 4 cu.yd. Cement is dumped from the hopper floor where the sacks are stored. Water is led in from a pipe delivering to the top of the hopper.

Concrete is delivered through the bottom hopper into the bottom dumping bucket of a conical shape somewhat similar in design to the individual bucket in the concrete mixer. These buckets have a capacity of 5 cu.yd., so that they are never overflowed by the delivery of one batch from the mixer. They are loaded on narrow-gage cars drawn by steam dinkeys and carried out under the cableway, where the buckets are picked up and swung out over the particular part of the work where they are required. The capacity of this plant is from 1200 to 2000 cu.yd. per day, but so great a capacity has never been required because of the difficulty of finding that much concreting to do in a work which consists of so many articulated small members.

Forms for the various parts of the work are standardized and have been, as a rule, used about four times for each form. About 1500 men are employed on the job.

The work is being done under the direction of the City of Cleveland, with C. W. Schulz, Commissioner of Water, and R. Winthrop Pratt, Consulting Engineer, F. H. Stephenson, Designing Engineer and R. S. Jones, Engineer of Construction, by the John F. Casey Co., of Pittsburgh and Cleveland. Ottomar Stange, of the firm, is in direct supervision of the work, and C. H. McAlister the Cleveland manager. E. J. Gass is chief engineer of the Casey Company, and D. F. Davison, superintendent on the work.

Proposed Standard Abrasion Test for Gravel*

The gravel is first screened through screens having circular openings 2 in., 1 in. and ½ in. in diameter. The sizes used for the test are equally divided between those passing the 2-in. and retained on the 1-in. screen, and those passing the 1-in. and retained on the ½-in. screen. The material of these sizes is washed and dried. The following weights of the dried stone are then taken: 2500 grams of the size passing the 2-in. and retained on the 1-in. screen and 2500 grams of the size passing the 1-in. and retained on the ½-in. screen. This material is placed in the cast-iron cylinder of the Deval machine as specified for the standard abrasion test of broken stone for road-metal.

Briefly described, this machine consists of a frame and two or more cylinders mounted at an angle of 30° with the axis of rotation. The cylinders are of the following size: 20 cm. diameter x 34 cm. deep, inside dimensions. Six cast-iron spheres 1.875 in. in diameter and weighing approximately 0.95 lb. (0.43 kg.) each are placed in the

*Result of an investigation conducted by the Bureau of Tests of the Ohio State Highway Department; published in full in the Ohio State Highway Department Monthly for August, 1914.

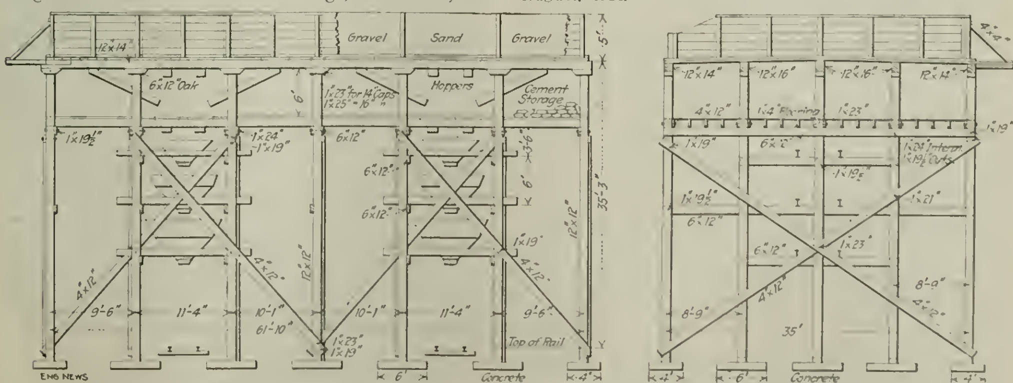

FIG. 3. DETAILS OF CONCRETE-MIXING PLANT FOR CONSTRUCTION OF CLEVELAND FILTRATION PLANT

cylinder as an abrasive charge. The iron composing these spheres, which are the same as those used in the standard paving-brick rattler test, have the following limits of composition:

Combined carbon	Not under [illegible]
Graphitic carbon	Not over 0.[illegible]
Silicon	Not over 1.[illegible]
Manganese	Not over [illegible]
Phosphorus	Not over 0.[illegible]
Sulphur	Not over [illegible]

After the cast-iron spheres have been placed in the cylinder the lid is bolted on and the cylinder mounted in the frame of the Deval machine. The duration of the test and the rate of rotation are the same as specified for the standard test for stone, namely, 10,000 revolutions at a rate of 30 to 33 r.p.m.

At the completion of the test the material is taken out and screened through a No. 16 mesh screen. The material retained upon this screen is washed and dried and the per cent. loss by abrasion of the material passing the No. 16 screen calculated.

As a means of comparing the results obtained from this test with those from the standard stone test, a series of tests were made using the rounded, or abraded, stone from the latter test, but of the sizes and proportions adopted for the gravel test. In order to obtain a sufficient quantity of the smaller size it was necessary to break up an additional amount of stone and subject it to the abrasion test, until all the corners and edges were rounded off.

The advantage of this test over the standard stone test for coarse gravel, aside from the consideration of the use of material, is the increased severity of the abrasion on the soft friable sandstone pebbles and material of a similar nature. In this test the impact of the cast-iron spheres breaks up the soft pebbles, while in the stone test the impact of the stone on stone merely tends to round off the corners and edges.

As the purpose of this test was primarily to indicate the presence of material having a low resistance to wear it is believed that it will be of special value when applied to gravel to be used in concrete which is subjected to wear or abrasion, as well as to gravel for road surfacing.

The use of gravel for both purposes is constantly increasing and the development and examination of the material has become an important industry.

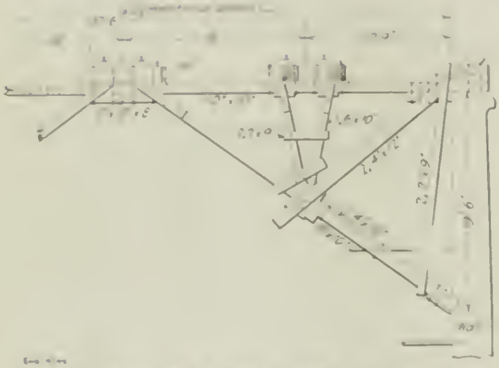

FIG. 1. TYPICAL TRUSS FOR SUPPORTING WORK TRAINS ON EASTERN VIADUCT

Pneumatic Tampers on an Unusual Earth-Filling Job

A most interesting earth-filling job is under way at the Eastern Viaduct of the New York Connecting R.R., Astoria, L. I. The structure is part four-track steel viaduct and part a retaining-wall structure with earth filling. The earth fill work in the latter portion involves several novel features, the most important of which is the use of power tampers.

Work trains bring the earth to the top of the viaduct and dump it between the retaining-walls in four windrows. It is then spread to a 12-in. layer and tamped to a crown (slopes of $\frac{1}{4}$ in. per ft.). The tampers are of the hand-manipulated pneumatic type, illustrated by Fig. 2, as furnished by the Ingersoll-Rand Co. for foundries. A maximum of 10 tampers has been in operation simultaneously on this job, although 20 are at hand.

The viaduct is of unusual construction. Thin reinforced-concrete walls stiffened by tie-rods and cross walls retain the fill, which is tamped and drained to secure the minimum pressure. The side walls vary from 35 to 70 ft. in height and are 3 ft. thick at the top, with stepped footings 6 ft. wide at the base. They contain no expansion joints. The right-of-way here is quite expensive, which makes an embankment too costly. The concrete viaduct was chosen because it was less expensive than steel.

DESCRIPTION OF THE WORK

The fill, which is a mixture of sand, gravel and loam, is obtained free from the Sunnyside yards of the Pennsylvania R.R., about $3\frac{1}{2}$ mi. distant from the site. A steam shovel of $2\frac{1}{2}$-cu.yd. capacity loads the earth on dump cars coupled in 11-car trains drawn by an 18-ton

FIG. 2. TRAVELING DERRICK SETTING FALSEWORK ON VIADUCT

dinkey engine. The cars are rated at about 3.8 cu.yd. each, and from 270 to 300 cars are handled per day. The loaded trains go up on the viaduct by means of trestling. The tracks are carried on transverse timber trusses resting on the side walls of the viaduct, as sketched in Fig. 1. When a bay is filled, the switch tracks and truss caps are removed; the remainder of the truss is left buried in the fill.

That the tamping to a crown may be reasonably accurate, the inspector for the railway marks on the wall the lines to be followed by the tampers. Measurements are taken from the transverse tie-rods between side walls. These tie-rods are an obstacle to rapid tamping, as, whenever they are encountered, tamping must be suspended while the rods are incased in concrete. The tie-rods are spaced 10 ft. apart both in vertical and horizontal planes. In placing, they are lifted in slabs projecting from the

FIG. 3. "CROWN" POWER TAMPERS AT WORK NEAR AN ARCH RIB

FIG. 4. SHOWING TAMPED SURFACE

side walls, by means of turnbuckles. The rods are placed when the tamping has reached a position 4 or 5 ft. below the stubs. When the fill has reached the rods, wood forms are placed around them and filled with 1:6 concrete, which is permitted to set for 24 to 48 hours, depending on the weather.

The first section of the work was completed Aug. 15; about 14,000 cu.yd. of fill were placed. During the work on this section, other parts of the fill were in progress. The total fill will amount to about 200,000 cu.yd., distributed over a distance of about ¾ mi.

FIG. 5. SHOWING RUBBLE DRAINAGE CHIMNEYS AND TIE RODS

Chimneys (2x3 ft. in plan) rise from weep-holes at bottom of sidewalls, to top of fill. View shows tie rods ready for concrete forms.

Air for the tampers is supplied from a compressor rated at 946 cu.ft. of free air per min., 100 lb. per sq.in. pressure, driven by a 150-hp. motor. The plant is located at Potter Ave., whence a 3-in. air line extends westward to the East River, a distance of 1400 ft. The last several hundred feet of line are reduced to a diameter of 2 in. Another air line runs eastward along the viaduct a distance of 2100 ft. The 1-in. air hose of the tampers is connected to a 10-part manifold. One of these manifolds is provided in each bay in which tamping is in progress.

An interesting feature of the fill is the rubble-chimney construction which rises from weep-holes in the lower part of the viaduct wall for draining the bays. Rock packing is also placed between stiffening ribs of abutments and part way up the rear of the street arches. This chimney construction is illustrated in Fig. 5.

Number of Men—The steam-shovel gang at Sunnyside comprises an engineer, fireman and craneman. There are six men in the pit gang. Each of the five trains in operation carries an engineer and a brakeman. Five laborers and a foreman dump the material from the top of the viaduct. Below in the bays, there are 45 laborers, two foremen, and six tampers. The concreting of the tie-rods is done by 12 laborers and a foreman. The fill proceeds at the rate of about 2 ft. vertical per day. Two machinists are employed to insure the smooth operation of the tampers.

Personnel—The work is being done for the New York Connecting Ry. (G. Lindenthal, Consulting and Chief Engineer) by Holbrook, Cabot & Rollins, New York City. The work is carried on by the contractor under the direction of T. B. Bryson. The superintendent at the site is Wyllys Russell.

A Fractured Pipe Casting on the Catskill Aqueduct That Sealed Itself in Service

By A. W. [illegible]*

A manhole casting, one of several large special pieces inserted on the line of the Catskill Aqueduct in the Bryn Mawr connection chamber—the point of junction between the Bryn Mawr steel pipe siphon and the Yonkers pressure tunnel—recently cracked and sealed itself in peculiar fashion. The casting did not fail completely, the crack being about 3 ft. long with an opening midway of its length of 1/8 in. The casting was under pressure from water impounded for a hydrostatic test of the Yonkers pressure tunnel. The leakage was considerable at first but, as time went on, the flow slackened and at last

FIG. 1. THE FRACTURED MANHOLE CASTING IN THE BRYN MAWR CONNECTION CHAMBER

(Looking down on casting; the crack is under the [illegible] [illegible])

ceased altogether, due to deposition in the crack of a hard, white substance that finally completely filled the opening.

The details of the design and construction of the work in this vicinity were given in an article in ENGINEERING NEWS, Sept. 21, 1911. The casting is roughly 6 ft. in diameter, 7 ft. 1 in. long, 2 1/4 in. thick. It weighs 13,700 lb., and has a manhole on the top 3 ft. in diameter.

The crack extended to both flanges (see sketch) but did not pass through either. It was fairly straight, passing practically radially through the shell. The maximum opening occurred on the horizontal part of the pipe next to the manhole. The cause of the fracture cannot be noticed outwardly as the casting is still in place.

The tunnel was being filled to elevation 295, the hydraulic grade (by pumping from a nearby stream), in order to test it under conditions approximating those of actual service. The elevation of the casting is 127.5, the head on the casting in service being thus about 168 ft. The fracture occurred probably between 5 and 8 a.m., Jan. 6, 1914. No one was present; it was discovered at 8 o'clock. As determined from evidences on the walls of the uptake shaft at Hill View reservoir, the water had reached elevation 227.9 when the fracture occurred. Pumping was discontinued and no attempt was made to stop the escaping flow, which at that time was gaged at about 158 gal. per min. After a couple of weeks, it was noticed that the flow was diminishing. After a month had elapsed, the leakage amounted to less than 1 gal. per min., and in two months had ceased entirely, even with the head restored to within a few feet of that at which the break occurred.

The following table gives the leakage and the corresponding elevation of the water in the tunnel. The various fluctuations of the water level were due to a continuous leakage into the tunnel, which gradually exceeded the

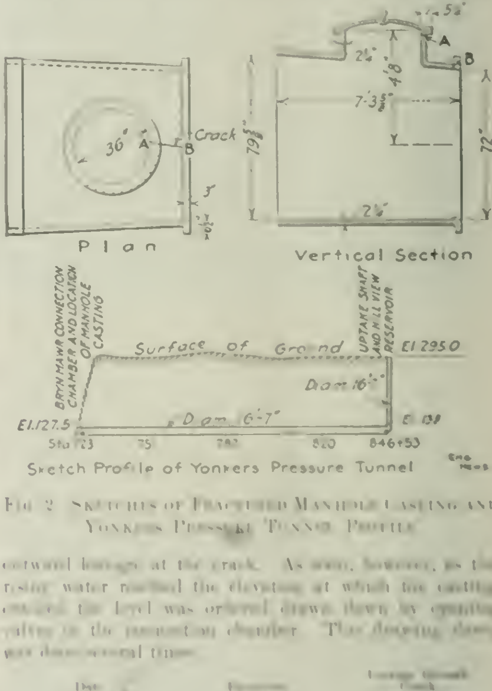

FIG. 2. SKETCHES OF FRACTURED MANHOLE CASTING AND YONKERS PRESSURE TUNNEL PROFILE

outward leakage at the crack. As soon, however, as the rising water reached the elevation at which the casting cracked, the level was ordered drawn down by opening valves in the connection chamber. This drawing down was done several times.

Date 1914	Elevation of Water	Leakage through Crack Gal. per Min.
Jan. 6	227.9	Pumping discontinued
Jan. [illegible]	[illegible]	158 approximately
Jan. 10	[illegible]	[illegible]
Jan. 21	[illegible]	[illegible]
Jan. [illegible]	[illegible]	[illegible]
Jan. [illegible]	[illegible]	[illegible]
Feb. 3	[illegible]	[illegible]
Feb. [illegible]	[illegible]	[illegible]
Feb. 12	[illegible]	[illegible]
Feb. [illegible]	[illegible]	[illegible]
Feb. [illegible]	[illegible]	[illegible]
Mar. [illegible]	[illegible]	[illegible]
Mar. [illegible]	[illegible]	[illegible]
Mar. [illegible]	[illegible]	[illegible]
Mar. [illegible]	[illegible]	[illegible]

In order to avoid the delays due to the replacing of the fractured casting, it was banded with 1-in. rods as shown in the figure, five on the main portion and four on the dome, with a strip of soft sheet lead about 1/2 in. thick and 2 ft. wide laid over the crack. The bands were put on Mar. 10 and the water raised to the hydraulic grade Mar. 15. Twice after that date, on Mar. 18 and 20, the water was raised again to the hydraulic grade. No leakage occurred nor weakness developed, and

*Assistant Engineer, Board of Water Supply, City of New York, [illegible], Yonkers, N. Y.

the hydrostatic test was completed without further incident.

The hard, white substance that was deposited on the casting near the crack and wherever the spurting water struck was analyzed with the following results:

Silica, SiO_2	5.58	Magnesia, MgO	.56
Oxide of Iron, Fe_2O_3	1.30	Sulphuric Anhydride, SO_3	.44
Alumina, Al_2O_3	0.24	Carbon dioxide, CO_2	41.15
Lime, CaO	50.73		

The deposited material was chiefly carbonate of lime.

In April, after the tunnel was unwatered, a flocculent deposit was found to have collected along the entire length of the invert. Samples were taken near the manhole casting and at Stations 751, 782 and 820; the results of their analyses follow:

	Near Casting	Sta. 751	Sta. 782	Sta. 820
Silica, SiO_2, and insoluble silicates	*52.36	6.51	3.46	3.53
Oxide of Iron, Fe_2O_3	7.70	1.26	0.71	0.56
Alumina, Al_2O_3	5.04	4.31	2.12	0.71
Lime, CaO	10.62	40.02	47.19	48.97
Magnesia, MgO	1.53	5.18	3.19	4.10
Sulphuric Anhydride, SO_3	0.27	0.32	0.21	0.18
Carbon dioxide, CO_2	9.43	39.28	41.64	41.25
Organic and volatile matter	13.05	3.12	1.48	0.70

*Chiefly silt.

The silt is accounted for by the water for filling the tunnel up to the time of the fracture being pumped from a near-by stream. The lime was, of course, produced wherever there was percolation of ground water through the concrete tunnel lining.

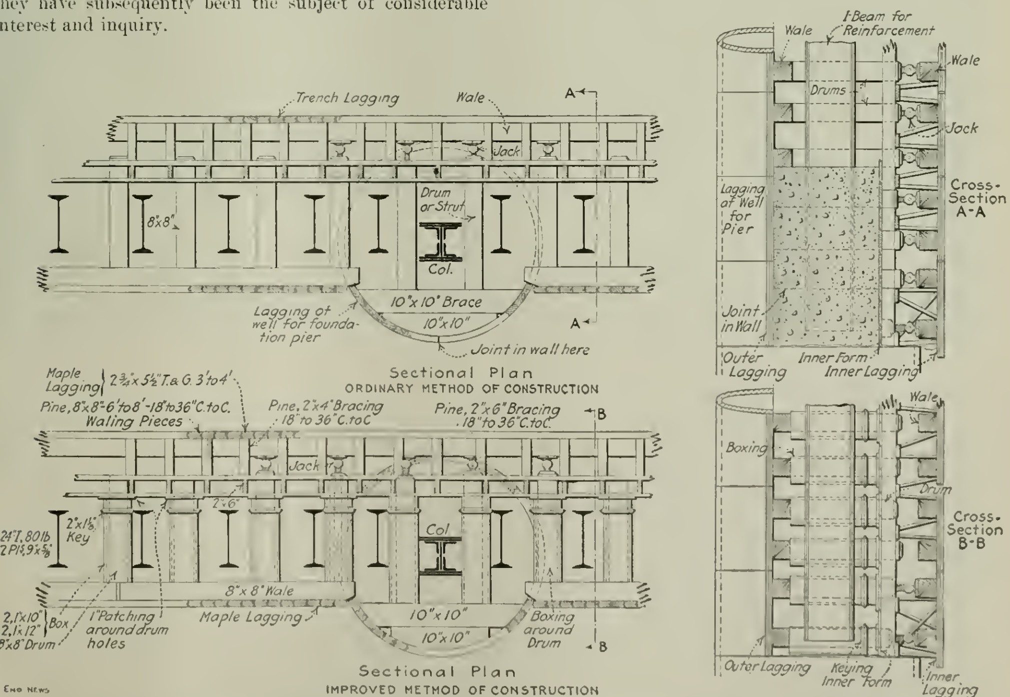
These disconnected details have been collected in this one article because, although each was a part of the day's work and not given much thought at the time, they have subsequently been the subject of considerable interest and inquiry.

Construction of Retaining Walls for Deep Basements in Clay Ground

In many of the large new office buildings in Chicago, having foundation piers sunk through the clay bed to rock, a portion of the area is excavated for two or three (or even four) basement floors. These excavations must be surrounded by heavy retaining walls to resist the pressure of the clay. The walls are built in trenches excavated to the required depth, lined with sheeting against which are placed waling timbers, braced by cross timbers or "drums" having a jack screw or trench brace between one end of the drum and the waling timber.

Ordinary Method of Construction

Under the ordinary method of building the wall, the forms are placed in position in the trench thus braced, and then concrete is deposited up to the level of the bottom of the first row of drums. This layer of concrete is allowed to set or harden for 12 to 24 hours. New drums are then placed behind the concrete-filled portion of the form. Then the drums and jacks of the row above the concrete are removed, after which the forms are set for the next course and another layer of concrete is deposited to fill to the level of the next row of drums. This is indicated by the horizontal dotted lines in the upper drawing of the accompanying cut, and the operations are continued successively until the top of the wall is reached.



Methods of Constructing Retaining Walls for Deep Basements in Clay Soil at Chicago

The upper drawing shows the method ordinarily used. The lower drawing shows the improved method employed by Holabird & Roche on the new Lumber Exchange Building.

The inner lagging is left in place, but the outer waling timbers are removed at the same time as the drums.

This method has several disadvantages, one of them being the slow rate of progress on work where rapid construction is usually most desirable. Then, the walls are not monolithic, but are composed of a series of separate horizontal courses, and although these are united by keys or joints, the arrangement is not well adapted to resist heavy lateral pressure. Certain floor panels in the floors above must be left open to allow of placing a reinforcement of vertical steel beams, as it is not satisfactory to use steel rod reinforcement, owing to the large number of horizontal joints and the difficulty of taking care of these. The pressure of the earth also has to be resisted by the green concrete, which in many cases is displaced or distorted to some extent. This allows a movement of the clay body which may affect adjacent buildings.

New Method of Construction

In the construction of the Lumber Exchange Building, at La Salle and Madison Sts., a new method was adopted for building the sub-basement retaining walls, the lower sub-basement floor being about 50 ft. below the street. The trenches were excavated in alternate sections, the joints being at the centers of the columns. They were 6 ft. wide, and sunk in 3-ft. lifts, each lift sheeted with 3x6-in. vertical lagging and two lines of 8x8-in. horizontal waling. The 8x8-in. drums were then placed between the waling timbers and made as tight as possible by the screws. This process was continued lengthwise in 6-ft. sections along the trench, and then downward to the desired elevation.

After the excavation of the trench was completed about 6 in. of concrete was deposited for a working floor and forms were built for the full height of the wall. The forms were cut away around the drums, which were boxed in or cased with 1-in. lumber; ribs on the boxing formed grooves or keys for bonding with the concrete filling later.

Then the trench was concreted from base to top in one operation, thus giving a homogeneous or monolithic wall, which was allowed to set for about two weeks, the pressure of the earth during that time being resisted by the drums or struts and not by the forms and concrete as in the other method described. The outer waling and lagging are left in place. When the basement is excavated the inner lagging is removed, the drums are pulled out of their boxing, and the inner form and boxes taken down. The holes left by the boxes are then filled with a dry concrete, well rammed, which is held in place by the notches or grooves formed by the keys. This method is shown in the lower drawing.

The advantages of this method are that the work progresses much more rapidly and gives a monolithic construction, while it eliminates the objection to rod reinforcement of these walls (though in this case some of the walls contain I-beam reinforcement). Another important advantage is that the drums take up the pressure, and relieve the wall of all pressure until the concrete has become thoroughly set and hard.

The building in question is a [illegible]-story office building about [illegible] ft. high above the street and with its sub-basement (for boiler rooms) 50 ft. below the street. The prevention of any movement of the clay bed was very important, since the [illegible]-story Y. M. C. A. building with floating or grillage foundations adjoins the south side of the site, while the 13-story Tacoma Building, also with float foundations, is across the street, and an old 3-story building with surface foundation is adjacent.

The architects are Holabird & Roche, of Chicago, and the new method of basement wall construction was devised by them. The George A. Fuller Co. is the general contractor. The structural steel was furnished by the American Bridge Co., and erected by the Oscar Daniels Co., while the shoring was done by the Reed-Neilson Co.

Commissary Supplies on a Canadian Survey

The question of commissary supplies for field parties is always of interest. We give herewith a table of the quantity and cost per man per day at a main camp for survey work on the Abitibi River, in the northern part of Ontario, in the winter of 1913. It is taken from a paper on "Contour Surveys on the Abitibi River," by H. T. Routly, in the annual report of the Association of Ontario Land Surveyors, at Toronto. The average number of men boarded was 18, including the cook. In a brief comment upon this list Mr. Routly says:

"We have always believed in feeding our men what they liked, within reasonable limits, and it is interesting to note the difference in requisitions of different parties.

CONSUMPTION OF FOOD AND SUPPLIES BY A CANADIAN SURVEY PARTY

(The figures are the amount per man per day.)

Supplies	Quantity per day	Cost per day, cents	Supplies	Quantity per day	Cost per day, cents
Apples	.035 lb.	.541	Matches	.0[illegible]6 box	.075
Apricots	.025 lb.	.135	Onions	.00[illegible] lb.	.199
Bacon, Br.	.215 lb.	6.136	Peaches	.02[illegible] lb.	.3[illegible]0
Bacon, L. C.	.475 lb.	7.482	Peas	.019 lb.	.195
Bacon, pickled	.022 lb.	.315	Pepper	.007 lb.	.100
Bak'g powder	.010 lb.	.165	Pickles	.002 gal.	.200
Barley	.005 lb.	.017	Potatoes	[illegible] lb.	.662
Beans	.120 lb.	.677	Potatoes, desic.	.0[illegible] can	2.[illegible]
Butter	.154 lb.	[illegible]	Prunes	.0[illegible]0 lb.	.362
Beef	.813 lb.	8.678	Raisins	.07[illegible] lb.	[illegible]
Candles	.178 candle	.752	Rice	.037 lb.	.176
Cheese	.061 lb.	.880	Rolled oats	[illegible] lb.	.179
Coal oil	.00[illegible] gal.	.077	Salt	[illegible]1 lb.	.088
Cocoanut	.002 lb.	.087	Soap	[illegible]1 cake	.188
Coffee	.017 lb.	[illegible]	Spice		.062
Corn	.061 can	.642	Sugar, brown	.178 lb.	.987
Corn flakes	.098 lb.	.867	Sugar, gran.	[illegible] lb.	1.398
Cornstarch	.001 pkg.	.026	Syrup	.007 gal.	.595
Cream	.200 can	3.172	Tea	.036 lb.	.818
Currants	.052 lb.	.884	Tomatoes	.073 can	.870
Flavoring		[illegible]	Turnips	.07[illegible] lb.	.0[illegible]5
Flour	.825 lb.	[illegible]	Yeast cakes	[illegible] box	.031
Jam	.015 lb.	.118			
Lard	.082 lb.	1.812			61.797
Macaroni	.117 lb.	.052			

The above table is simply an analysis of actual quantities and costs on this particular contract. A change of cooks will often make a great difference in the comparative amounts of various items used.

"In most of our northern work we used desiccated potatoes, but on this contract some of the ordinary tubers were used. These were frozen solid coming in, and it may be of interest to note that the best method of preparing frozen potatoes is not to thaw them with cold water, as is usually done, but to brush them clean, give them a quick rinse with hot water, plunge them at once into a pot of boiling water and cook them with jackets on."

Crowns for Road Surfaces—The committee on roads and pavements of the [illegible] recommends the following average crowns per foot for various kinds of road surfaces: [illegible]

NOTES

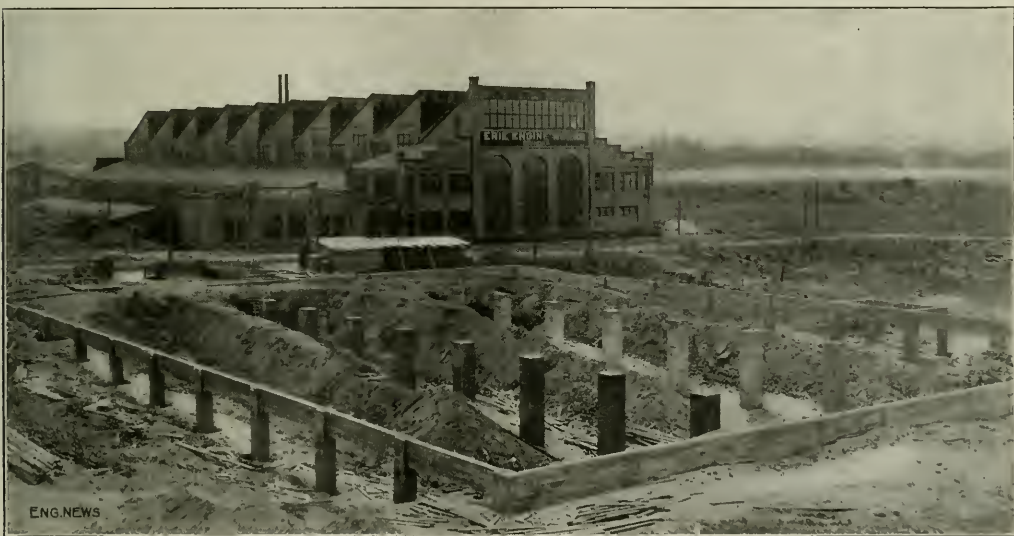
The Conventional Signs for Plans and Drawings compiled and adopted by the American Railway Engineering Association have been specified by the Valuation Board of the Interstate Commerce Commission for use on all maps and profiles employed in the railway valuation work now in progress. These conventional signs are now printed in pamphlet form (6x9 in.), with 12 pages relating to various signs for general maps, profiles and drawings, one page relating to riveted work and 12 pages relating to signal and electrical work (as adopted also by the Railway Signal Association). Several railways are ordering these pamphlets in large numbers for their engineering and drafting departments. Copies may be obtained from E. H. Fritch, Secretary of the Railway Engineering Association, 900 South Michigan Ave., Chicago. The price is 25c., but lower prices are made on orders for 10 or more copies.

Wall Girders in a Machine Shop Building—The walls of a new shop being built for the Ball Engine Co. at Erie, Penn., are carried in part by direct footings and in part by wall girders. This unusual combination is shown quite clearly by the adjoining photographs It was due mainly to the conditions of the subsoil.

The site was formerly a gravel pit, which had been excavated to an average depth of 12 ft. below grade and later partly refilled with foundry waste. This refill was not suited to carrying the column piers or the wall footings. The column piers were therefore carried down to the original bottom, which makes some of the large center piers 16 ft. high. At the rear wall the firm ground was near enough to permit of direct footings of relatively shallow depth, and the heavy weight of the front wall required continuous footings to be used here also. The side walls, however, carry only a 6-ft. height of 8-in. hollow-tile curtain-wall, and as they come over the deep part of the former gravel pit, a reinforced-concrete girder construction was employed to carry these walls, as shown. The space under these girders will be filled with earth.

The building is 150 by 200 ft., of steel frame and hollow-tile walls. The front and rear walls are respectively 16 and 12 in. thick, the side walls 8 in. The girders under the side walls are 12x36 in. by 20 ft. long, the spacing of column piers.

In constructing the foundation, two cuts were made through the waste refill with a steam shovel, to build the center piers. After completion, the whole was filled to grade. Constable Bros., of Erie, Penn., were the contractors. H. Edsil Barr, of Erie, Penn., acting as engineer for the owners, designed the construction.



Foundation of New Ball Engine Co. Shop, Erie, Penn.; Wall Girders for Side Walls, Direct Footings for Front and Rear Walls

The Novelty in Stadia Methods devised by J. Zwicky, of St. Gallen, Switzerland, and described on p. 747 of "Engineering News" of Oct. 8, calls to the mind of one of our readers, G. F. Schlesinger, of the department of civil engineering of the Ohio State University, the following simple method of getting approximate horizontal distances, for which he claims no originality, but which may be new to many readers:

The method, in brief, consist of turning off a horizontal angle of 1° 9′ with the transit, and then measuring the distance between the first and last pointings at the extremity of the course whose length is to be determined. This distance in hundredths of a foot, divided by 2, will be the actual distance in feet; depending, of course, on the fact that the sine (or tangent) of 1° 9′ is 0.02 (approximately).

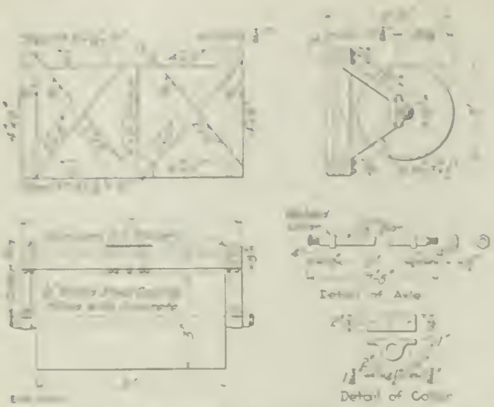
The angle of 34′ may be used, in which case the division by 2 is not necessary and the "spread" is one-half; but the approximation will be greater. The error due to the approximation using the angle 1° 9′ is 1 in 290, and, even in view of other inaccuracies, the results will be sufficiently close for certain classes of work.

By means of this method, remarkable progress can be made in determining small drainage areas by running an angle line around the divide; or, in some cases, by "side shots" from some central point or points within the area.

The party is composed of two men equipped with a plain transit, sight rod, metallic tape and ordinary chaining pin. The rodman selects the points ahead and the transitman takes the magnetic bearings of the courses (when practicable), then sets off the horizontal angle for lining in the rodman for the second pointing. The rodman, having inserted the pin, holding the ring at the end of the tape, at the first point, measures the distance to the second. After marking the first point so that it may be readily found by the transitman, he then proceeds to the selection of the next station, while the transitman moves up.

The following points can be made for this means of approximating horizontal distances: It permits the use of the plain transit reading to minutes with the ordinary cross wires, requires no stadia or level rod, no reduction to the horizontal, and longer courses can be taken than by the stadia or gradienter method. The transitman is not limited by the distance at which he can distinguish figures on a rod, but by the distance at which he can clearly see a sight rod.

Using Old Concrete Pavement Foundations—In New York we have laid both asphalt and stone pavements on the old concrete base. It is not all good, that is, we have to lay a certain amount of new concrete even on the old. The pavements are so cut up during the life of a useful pavement, for instance, 15 or 20 years, that the surface of the concrete foundation is very irregular after the asphalt is taken off. As a rule, it requires from 2 to 3 in. of new concrete to level it up.—George W. Tillson, in a discussion before the Cleveland Engineering Society.



HOME-MADE ROAD ROLLER

A Home-Made Road Roller for $75—Many [illegible] towns which cannot afford to own a steam road roller may construct a very satisfactory substitute in the following manner, according to Bulletin No. [illegible] of the Pennsylvania State Highway Department.

The roller consists of a [illegible]-in. thick rolled steel casing, properly riveted with rivets countersunk on the outside and [illegible] the inside of the casing, but if an old [illegible] of sufficient dimensions can be had, it will answer just as well. The axle is placed in the proper position and securely fastened, and then the casing is filled with concrete [illegible]. Great care must be taken not to disturb the axle from its proper position. The uprights on [illegible] which support the wooden frame are made from [illegible] shown in the sketch and can be [illegible] by a blacksmith. The frame consists of [illegible] timbers [illegible] bolted together; the [illegible] at the ends and fitted into each other [illegible] on top of each other [illegible] at the corners to give a [illegible] on each side of the frame for the [illegible] can be taken [illegible]

Heavy Hand-Operated Gate Hoists, New York Barge Canal—[illegible]

A HEAVY HAND-OPERATED GATE HOIST, NEW YORK BARGE CANAL

[illegible]

[illegible] lb. It was required also that the hoists should close the gates under load.

In the hoists furnished by the [illegible] Machine Works, Inc., of [illegible], N. Y., these requirements have been met by the construction illustrated herewith. The gate stems are [illegible]-in. steel I-beams carrying [illegible] plates on the lower flanges and [illegible] carry the rack [illegible]. Each gate stem runs between a flanged roller and a [illegible]-tooth cast-steel pinion with 7-in. face. The shaft carrying the rollers is [illegible] into the frames, the rollers turning on the shaft and not with it. There are [illegible] of gears and pinions connecting back to the handles, the reductions being respectively [illegible] and [illegible]. The [illegible]-in. arm and [illegible]-in. roller handle are detachable and may be slipped on the second gear shaft to give a higher lifting speed after the gate has been started. A cast steel ratchet and pawl on the shaft serve to hold the gate in any position. The heavy side frame castings are intended to be held in alignment principally by four $1\frac{1}{4}$-in. foundation bolts although there are three 1-in. separator rods.

To Prevent Wear of Concrete Floors, [illegible] the dust resulting from such wear under the influence of heavy trucking, etc., a chemical composition known as "[illegible]" is being introduced. This is applied to the surface of a new or old floor, and is said to be proof against water, oil, acids and alkalies, while it enters into intimate combination with the concrete and will not flake or peel off. It is manufactured by the Dustite Co., 661 Peoples Gas Building, Chicago.

Rust-Resisting Metal Sheathing—Three of the new steel frame pier sheds built at Seattle, Wash., by the Port Commission are sheathed with galvanized corrugated iron of a special grade, having a high degree of purity and consequently a high resistance to corrosion. These properties are expected to make the sheathing durable and economical even under the influence of the damp [illegible] air of the water front at Seattle.

The metal used is known as [illegible] iron, for which 99.80% of pure iron is guaranteed. Analyses by three commercial testing laboratories showed: Carbon, 0.011 to 0.[illegible]; silicon, trace to 0.001[illegible]; sulphur, 0.017 to [illegible]; phosphorus, 0.004 to 0.006[illegible]; manganese, 0.0[illegible]; copper, trace to 0.025[illegible]; oxygen (given by one analysis only), [illegible]; total impurities, 0.116 to 0.12[illegible]; total purity, [illegible]. The makers state that a general average is [illegible] oxygen, 0.0[illegible] nitrogen and 0.00[illegible] hydrogen. A comparison of three physical tests showed the following: Elastic limit, [illegible] to 32,[illegible]00 lb. per sq.in.; ultimate strength, [illegible] lb. per sq.in.; elongation, 32.7[illegible]; reduction of area, 63[illegible] to 71[illegible].

This metal has been used also for roofing, culverts, window frames and sashes, and a variety of other purposes where an important consideration is resistance to rust or corrosion due to moisture, acid fumes and other destructive influences. It is manufactured by the Inland Steel Co. of Chicago, which uses only pig iron and the crop ends from the steel mill, no scrap being allowed in the [illegible]; this is believed to secure high strength in combination with a low percentage of carbon, phosphorus, sulphur and manganese.

Motor Trucks for Water-Works Service—For several years it has been apparent that the work of the Water [illegible] could be made more efficient by substituting automobile trucks [illegible]

[illegible]

Editorials

The Abandonment of a Railway Line

A railway 90 miles long in Western New York was to be abandoned on Nov. 1, according to an order issued by the New York Supreme Court, which has directed the receiver of the property to cease all operation of trains and take up the track. The railway in question is that part of the Buffalo & Susquehanna Ry. extending from near Buffalo southeast to Wellsville. The company owning the road has been in the hands of a receiver for over four years. The court's action in ordering the discontinuance of operation of the road and the taking up of the track was made on petition of the United States Trust Co., of New York, the trustee for the bondholders of the company.

The facts appear to be that the road in question is the least profitable part of the Buffalo & Susquehanna line to operate. Lines located further south in Pennsylvania do an extensive coal business, but the difficult grades to the north make it cheaper to send the coal to lake ports over other roads than to haul it over the Buffalo & Susquehanna line from Wellsville. Undoubtedly, the bondholders have the right to stop operating an unprofitable property and to get what little salvage they can out of it by taking up the rails. This salvage will be small, however; for under present market conditions, relaying rails are salable only at a very low price.

The abandonment of the road will be a serious matter to the farming communities along it which depend upon it for transportation. The roadbed and tracks are in good condition, and represent an investment that could not be replaced, probably, short of $2,000,000.

Residents along the line of the road appealed to the New York Public Service Commission. Through the efforts of that body, the execution of the Court's order has been postponed for one month. It is hoped that prior to Dec. 1, the date at which the Court's order is now scheduled to take effect, someone can be found willing to take over and operate the road.

Of course, it is impossible to operate a road with thin traffic, such as this line has, at any such low rates per passenger-mile and per ton-mile, as prevail on roads which do a large business. It would be far better for the farmers along the line to pay whatever rate is necessary to keep the road in operation rather than have it stop operations entirely. More economical methods of operating the road could doubtless be introduced, such as substituting independent motor cars for regular steam-locomotive train service.

Such instances as this form a useful lesson as to the inevitable result where a railway is unable to earn enough to pay its operating expenses and make some return, at least, to those who have furnished the money to build it.

The railways are indeed public-service corporations and as such obliged to render reasonable service to all alike, so long as they continue in operation. But when any railway becomes unprofitable to its owners and they can see no hope for future profits, they have the undoubted right to do exactly what the owners of the Buffalo & Susquehanna R.R. propose to do—stop operations, take up the rails and sell them for scrap.

The only alternative to this would be the purchase and operation of the railway by the government, state or federal; but even if this were done, the necessity would remain of charging rates on passenger and freight traffic sufficiently high to pay at least the operating expenses and a safety margin over. It could hardly be expected to make up the deficit by laying a general tax on the public.

The Development of Sand and Gravel Deposits

The enormous development in the use of concrete in engineering construction which has taken place during the active life of men who still call themselves young, has been the chief influence in the rapid growth of two collateral industries, namely, the quarrying and stone-crushing business, and the utilization of sand and gravel deposits.

It is probably true that the value of gravel, properly cleaned and graded for use in making concrete material, has not been properly appreciated by the engineering profession until very recently. The old idea dies hard that the rough surface of broken stone made a stronger bond with the cement than the smooth surface of water-worn gravel, notwithstanding the numerous tests which have proved the perfect bond of the cement with the smooth gravel or stone.

It is now realized, however, that for reinforced-concrete work a good gravel concrete will run equally as well if not better around reinforcing bars than concrete made with broken stone; and where clean gravel is obtainable at a low price, there is every reason why it should be used by the engineer. In concrete-road construction, admittedly the most severe service to which concrete is now applied, a large proportion of the concrete roads thus far constructed have been built with gravel instead of broken stone as the aggregate.

The great increase in the market for sand and gravel has been accompanied by rapid developments in plant and machinery for handling these materials; and the design of such plants has now reached the stage where special knowledge concerning the operation of such a plant and the requirements to be fulfilled is necessary, if the best results are to be obtained in the operation.

While a number of descriptions of such plants can be found in engineering literature, there has nowhere appeared, so far as we are aware, any systematic discussion of the principles which should govern their design. We are, therefore, particularly pleased to be able to lay before our readers in this issue a paper dealing with this subject, prepared by an engineer who has had a number of years practical experience in the development and operation of sand and gravel deposits. The author of the article, W. H. Wilms, President of the Universal Sand &

Gravel Co., of Covington, Ind., has himself worked out the principles governing this class of work as a result of many years' costly experience in experimenting with different types of machinery and methods of operation. The article in this issue deals with the testing of sand and gravel deposits to determine their quality and the possibilities of their commercial development, and will be followed by succeeding articles dealing with the design and arrangement of the machinery and plant for operating such deposits.

Creosoted Wood-Block Paving Specifications to Prevent Bleeding and Bulging

The analysis of the new Kansas City specifications for wood-block paving, by Clark R. Mandigo, Assistant City Engineer of Kansas City, on another page of this issue is of especial interest to municipal engineers. In presenting the Kansas City specifications to our readers, however, it is worth while at the same time to call attention to the new specifications of the Bureau of Highways of the Borough of Manhattan, New York City. These are the result of a very thorough investigation and study by a staff of expert paving engineers, and they differ in some essential points from the Kansas City practice.

The New York City specifications cover much more fully than those of Kansas City, the kind and quality of wood and the treatment of the blocks. Only genuine Southern long-leaf pine, subject to inspection in the stick before being sawn into blocks, is acceptable in New York. This must be air-dried, so that the blocks as cut shall not weigh more than 50 lb. per cu.ft.

When ready for treatment the blocks are divided into four lots, according to their varying weights per cu.ft. Those weighing 38 to 42 lb. per cu.ft., 42 to 44, 44 to 46, 46 to 50 lb. per cu.ft. are to be treated in separate batches under varying conditions of steam pressure, temperature and vacuum. The lighter wood is subjected to less pressure than the heavier and to lower temperatures, varying from 2 hr. at 15-lb. steam pressure at 185° F., and a vacuum of 22 in. for 1½ hr., at 155° F., to 5 hr., at 25-lb. steam pressure at 220° F., and a vacuum of 24 in. for 2½ hr. at 140° F., for wood weighing 50 lb. per cu.ft.

Besides detailed specifications for each batch as outlined, the specifications further state that variations and changes may be required by the engineer from time to time in the duration of the treatment and in temperatures and pressures used, to suit the specific gravity of oil and different varieties of timber used. All blocks and materials are inspected at the plant, but acceptance at the plant is not final, the city reserving the right to reject shipments of block, as a whole or in part, after delivery on the work.

The New York specifications for the mortar bed (1 : 4) provide that the mixture shall be made dry and then slightly moistened before the [illegible] surface [illegible]. The mortar bed is also sprinkled immediately in advance of the block laying, [illegible] a different practice from that of Kansas City. No provision is made for [illegible] the blocks previous to laying, but it is specified that the blocks shall show such waterproof qualities that after being dried in an oven at a temperature of 100° F. for a period of [illegible] weighed and then immersed in water for a period of [illegible] and weighed again, the gain shall not be more than 5%. In laying, the blocks are specified to be laid loosely and not driven together—another difference from the Kansas City specifications. Either a coal-tar pitch or asphalt filler may be used.

On the other hand, experiments conducted by C. H. Teesdale, engineer in charge of wood preservation at the Forest Products Laboratory, Madison, Wis., tend to confirm the conclusions reached by those who drew the Kansas City specifications. These experiments were described in a paper read before the American Society of Municipal Improvements at the recent (October) meeting in Boston, Mass.

Mr. Teesdale's general conclusions are as follows:

These tests seem to indicate that longleaf pine paving blocks should be treated in the green condition after being well steamed. All blocks, even if thoroughly air-seasoned, should be well steamed. While it is true that a preliminary and final vacuum greatly retarded bleeding of air-seasoned wood, a preliminary vacuum will tend to make the absorption of oil too rapid during treatment, resulting in uneven penetration. A steaming period is therefore advisable to render the absorption less rapid and allow a longer and more intense pressure period to be applied. Furthermore, if seasoned blocks are steamed, they will take up moisture and expand and should be less liable to give trouble from swelling after laying in the street. For these reasons it would be preferable to treat green material when it is possible to obtain it.

If for any reason the blocks cannot be laid soon after treatment, they should be covered and perhaps wet down occasionally to prevent them from drying out. It is likely that if the blocks are wet when laid, expansion troubles will be much reduced, providing a good job of laying is done.

It would seem to be desirable to give a vacuum treatment after the steaming period and also after the oil has been removed from the cylinder. If tar mixtures are used, a final steam bath should succeed the final vacuum to remove carbon and dirt from the blocks.

Absorptions of over 16 lb. per cu.ft. hardly seem necessary. Data are available which show that heavier absorptions do not greatly retard swelling and they tend to increase bleeding.

It seems very likely that the reasons why some pavements bleed while others do not may very often be traced to the method used in treatment. A plant treating green material would resort to a steaming and vacuum treatment with the result probably, that the blocks would give no trouble. The same plant, perhaps, would later treat seasoned material without steaming it or giving it a vacuum treatment. This would be the simplest method of treating such timber as much time would be saved, and these operations would seem unnecessary. When such blocks are placed in the pavement, however, there is considerable probability that bleeding would follow.

The following conclusions were drawn from all the tests made on swelling:

(1) The rate of swelling was much slower in treated blocks than in untreated blocks. In all cases where the blocks were soaked in water the maximum swelling obtained was at least two-thirds, and in most cases was only slightly less than that of untreated wood.

(2) The maximum swelling was less in blocks treated with tar mixtures than with creosote.

(3) Free carbon did not appear to influence swelling.

(4) No swelling occurred in the case of wood treated in green condition.

Engineers and Civil-Service Examinations

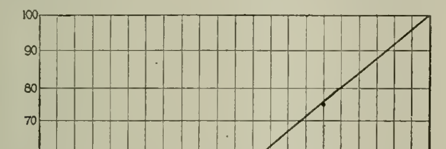
There can be no question that the engineering profession heartily supports the theory of what was known 25 years ago as the civil-service reform movement. It would be hard to find an engineer who would dissent from the proposition that appointments to positions in the public service, municipal, state or federal, should be based on the fitness of the applicant for the job and not on his political affiliations or his power to exert a pull.

But it is one thing to approve the theory of the merit system, and quite another thing to reach the conclusion that the average civil-service examination as it is con-

ducted actually does select the men or women who are best fitted for the work. It is a pretty general rule, we believe, that when an engineer is placed in responsible charge of work, and has to select the employees who are to carry out the work under his direction, he does not ordinarily appeal to the civil-service bureau for candidates unless the law obliges him so to do.

This applies especially to the higher positions, involving more or less of responsibility and originality in the men who are to fill the positions; but it applies also to the lower grades of city employment. Unless the bureau conducting the civil-service examinations goes at its job with the same common sense that should prevail in the employment bureau of a factory or a large mercantile establishment or a general contractor's organization, the examination of men for employment in the work of cleaning streets, excavating sewers, laying paving, firing boilers, and twenty other similar tasks in the municipal service is not likely to secure the men best fitted to perform the work.

An excellent statement of the engineer's attitude toward civil service in connection with a city's business is contained in the annual report, just issued, of Morris L. Cooke, Director of Public Works of Philadelphia. As



Percentage Allowed to Previous Experience in Civil Service Examinations for Engineering Positions in Cleveland, O.

many of our readers are aware, Mr. Cooke holds probably the highest administrative position in the service of a great city of any member of the engineering profession in the United States. He represents the reform element in politics, and has introduced into the public service of Philadelphia standards of efficiency such as have seldom been seen in that city. Mr. Cooke says:

> We wish to register a deepening conviction that some form of civil service is absolutely necessary for a proper conduct of municipal business. Were it not for civil service, the life of the average administrator would be almost unbearable.
>
> At the same time we are convinced that the civil-service system in this country is suffering from an overconfidence in its methods by those administering it. We believe that over a large part of the field the methods used are archaic; that as the grade of the position to be filled rises, the present methods of examining are less and less likely to produce the right kind of man. The civil service should be looked upon as corresponding to an employment bureau in the ordinary industrial establishment.
>
> Among the changes which would appear to be for the good of the system are: That the appointing officer should be allowed greater scope in signifying the particular type of employee he wants at any given time; more weight should be given to a candidate's previous experience and record and less to what he is able to submit in a four-hour examination; promotions should in greater measure be dependent on record of work done rather than on examination; civil service should be operated, primarily, to promote efficiency rather than to check favoritism.
>
> Methods should be adopted that will obtain quicker results from examinations. In departments such as those where there is a great deal of construction work that is not routine and which varies in amount from season to season, it is necessary at times to increase quickly the force in certain divisions. The most desirable candidates will not wait around two months after an examination to find out whether they are to be available for appointment.

We wish that Mr. Cooke's comments above quoted might be read and taken to heart by all those charged with the responsibility of conducting civil-service examinations. The fact ought to be recognized that there are a large class of men who are competent and efficient in doing work but who can by no means attain a high mark in an examination.

Worth especial notice in this connection is the method adopted in the City of Cleveland a few months ago to comply with the civil-service law and at the same time meet the practical needs of municipal service.

The new Cleveland charter, which went into effect at the beginning of the present year, made it unlawful for a city disbursing officer to pay an employee in the classified service unless the city Civil Service Commission had certified to that person's appointment in accordance with the civil-service provisions in the charter. The charter, however, provided that:

> All examinations shall be practical and impartial, and shall relate to those matters which will fairly test the relative capacity of the person examined to discharge the duties of the position for which appointment is sought.

The Cleveland Civil Service Commission is composed of two lawyers and a chemist. After a rather unsatisfactory experience in having its papers for the examination of engineering employees prepared by examiners selected by the Commission, an appeal was made to the Cleveland Engineering Society for aid.

The society at once appointed a special committee which prepared lists of those members of the Society who were by previous training and experience best qualified to prepare examination questions for the various positions. From these lists a subcommittee of two was selected for each examination.

Consultations were held by the committee and the various subcommittees with the commission as to the routine and scope of the work and the relative weights to be given to examination and previous experience. It was felt that in the subordinate positions it is of importance that a man should have thorough technical knowledge but that as responsibility is increased, experience becomes the most important thing. This was apparently recognized by the framers of the charter when they conferred upon the Commission power to exempt certain positions from the competitive class.

It was necessary to reduce this general idea to a definite basis and the committee finally decided that a position paying not more than \$800 a year might be filled by a man with no previous experience, while one paying \$3000 or more should require a man of such extended experience that his early technical knowledge might be relatively of no importance. Between these two extremes the weight of experience was made relative to salary on a nearly straight line, as shown on the accompanying cut.

Letters to the Editor

Experience with Small Cube Granite Block Pavements in Louisville, Ky.

SIR—Supplementing the article in ENGINEERING NEWS, Sept. 10, 1914, on "The Present Status of Small Cube Granite-Block Pavements," the following facts regarding Louisville experience may prove of interest. The Department of Engineering has recently laid about 600 sq.yd. of this pavement in the car tracks on Main St. between 7th and 8th St. The blocks were purchased from the Harris Granite Quarries Co., Salisbury, N. C., and cost $9.00 per ton f.o.b. Louisville (7 sq.yd. to the ton guaranteed). The blocks measure from 3¾ to 4 in. and are in the form of irregular cubes.

The foundation for this pavement is portland-cement concrete extending from a line 6 in. below the ties to a line 5½ in. below the head of the rail. On the concrete foundation was spread a course of pea gravel or roofing gravel in which the blocks were set in straight courses perpendicular to the rail. No especial effort was made to break the joints as this was accomplished by the irregular sizes of the cubes. After laying, the blocks were rolled with a 2½-ton tandem roller and grouted with a portland-cement filler.

To date, the pavement is entirely satisfactory and presents a beautiful appearance, but the short time it has been in use, about three months, is not sufficient to furnish any reliable information.

The cost of the blocks on the railroad cars was 67c. per sq.yd. less than standard-size blocks would have cost from the same quarry, and the amount of filler used was about the same required for standard blocks. However, the cost of paving was considerably higher, as we could only secure a maximum of 20 sq.yd. per man per day of 8 hours, whereas on standard blocks we have no trouble in getting 30 to 35 sq.yd. per man. Granite pavers of this city are paid 50c. per hr., or $4.50 per day, consequently it will be seen that it cost about 50% more to pave with the cubes than with the standard blocks. It should be remembered in this comparison, however, that these blocks were used in the car tracks which always cost more than paving larger areas.

This experimental section of "Durax" pavement has given such favorable impression that we have just awarded contracts for laying 1000 sq.yd. of it on another street. The lowest bid on this contract was $3.40 per sq.yd. including 5-in. concrete base and portland-cement filler.

While we think this price is a trifle high, we account for this largely by the fact that the pavement is practically an unknown quantity to local contractors and we think they have added a liberal margin for safety. We have decided, however, to let the contract at this figure hoping by securing some payment on it to show that it can be laid considerably cheaper than $3.30, and in this way we expect to bring the price down to a more reasonable figure.

From our investigation of this pavement and our slight experience with it we are so favorably impressed that we hope to be able to lay larger yardage of it in the future if it can be done at a reasonable figure.

D. R. LYMAN,
Chief Engineer, Department of Engineering.
Louisville, Ky., Sept. 19, 1914.

Slighting the Humble Land Surveyor

SIR—I have often wondered why that part of engineering dealing with land surveying has apparently not received in the periodicals of the day the amount of attention and discussion it deserves. Is this because there seems to be a quite general belief, even among engineers, that anyone who can run a transit and read a tape is a surveyor?

A case in point might readily be found in the report of the Committee of the Philadelphia Association of Members of the American Society of Civil Engineers, printed in ENGINEERING NEWS, Oct. 22, 1914, pp. 850-852. After setting forth in an able manner indeed, a number of arguments against the proposed act and its principles covering the licensing of professional engineers, the committee recommends a plan, to quote, in part:

To require the licensing of county surveyors and other surveyors in independent practice. Fair examinations for surveyors can easily be set, which would serve to exclude incompetent men where incompetency would be likely to entail property losses and expensive litigation.

To license other classes of technical men whose duties are of a definite and restricted nature in fields where incompetency would be attended by results similar to those just mentioned in connection with surveyors and in which competency may readily be determined by examination.

Here is clearly a case where land surveying is regarded as a fixed and definite proposition, as much so as a problem in trigonometry. The committee report would lead one to believe that its members feel that given a set of circumstances and data, there is in all cases but one correct procedure for a good, let us say a "properly licensed" surveyor to take.

Unfortunately, this is not true. The first part of paragraph (b) under heading (A) in the above report is a good answer to the proposed plan to license surveyors anywhere, for in what part of engineering work is there more judgment required than that of the land surveyor? Besides having often to interpret deeds, descriptions, laws, titles and right of possession, he is obliged to use extraordinary care and all of his experience, in order to insure accuracy at all times in "every measurement." In practice, this is not a matter of running a transit and reading a tape, as a glance at some of the U. S. Coast and Geodetic Survey reports, covering accurate measurements of various kinds will prove.

To quote again from the above report:

It may, in fact, be generally admitted that no form of licensing can serve to eliminate incompetency, though technically competent men will not hesitate to resort to

unprofessional practices insofar as that may be possible with safety to themselves.

Where in the whole field of engineering is there another department, like land surveying, where competition is as keen, with its resultant price-cutting and lowered quality of work, and by reason of the almost criminal lack of proper laws, the chance for careless and troublesome practices so great?

It is true that the land surveyor has not the responsibility of the danger of a catastrophe resting upon him; but from a theoretical point of view there is more judgment, or say more educated common sense, required at times in land surveying than in the design of a bridge or other structure of more or less standard specifications.

The writer is not opposed to the licensing of surveyors as a general proposition since this would perhaps require a working knowledge of mathematics at least, among the "surveyors." The true remedy, however, in my belief, is in the enacting of proper laws covering land descriptions, plats, monuments, etc.

MATHIAS R. KONDOLF.

P. O. Box 713, Rochester, N. Y., Oct. 24, 1914.

A Defense of Railway Location Theories for Highway Location

Sir—In your issue of Aug. 6, 1914, there was a letter under the title of "Highway Location in Mountainous Country." I wish to mention the experience of the writer on highway work with engineers "who had sat at the feet of Wellington," or other high authorities on railway location, and who, the author of that letter seems to think, are not particularly qualified for highway-location work.

In the Philippine Islands we have had engineers with highway, railway and other special experience, and engineers just out of school with no practical training at all.

Where one location made by the railway engineer has been found wanting, a dozen made by men with other than railway experience have not come up to the requirements. Engineers with former highway experience were not found to have any marked advantage over those without railroad experience.

It is an extremely rare occurrence that we have to request the ex-railway engineer to break his grades at more frequent intervals, or that we have to increase his rate of grade or cut down the radius of his curves. On the other hand, it is the rule rather than the exception that the locations made by the non-railroad men are noticeable for the following defects; adverse grades (often maximum both ways), when a broken or uniform grade can be had for the same or but little greater expense, and in some cases for even a lower cost than for the adverse grade (usually there is no attempt to locate these grades with any regard to momentum factors); poor alignment; excessively sharp curves without any reason for their adoption.

We have a form of parabolic curve in the engineers' manual, which can be advantageously used in some cases. This curve may be easily located by offsets.

A common method used by some non-railway engineers is to run in their curves with a certain length of tangent distance, which length remains practically constant for a section of location, with little or no attention to the amount of angle, topography or other conditions. These engineers assume that a tangent distance of say 100 ft will get them around almost any angle and they are content. Frequently curves of from 1° to 20° or more will be made where a tangent would not cost a cent more.

These cases often occur in a country where a swing sufficient to give a straight line would not make any difference in the grading required. This generally comes from running to a point where the locating engineer discovers he has to make a turn to strike his objective point. Light angles come in frequently from getting off a back sight or other cause; but such little things as a rule do not bother the man who has not "sat at the feet of Wellington." However, such defects do not pass entirely without notice from the more or less critical nontechnical users of the road.

The railroad engineer has an eye for country and has methods of overcoming difficulties in grade and alignment, which are not possessed by one engineer in a hundred who has not had his experience or worked on location under the direction of a highly qualified location man.

The writer of the letter in your Aug. 6 issue states: "Highway location is still in its infancy, and a few more railroad ideas will have to be almost forgotten." After going over considerable highway work in the United States, Europe and the Malay States and having had about eight years' experience on road location and construction in the Philippine Islands and Cuba, I believe that the last phrase would be decidedly of more value to the highway cause if it had read "a few more railroad ideas will have to be kept in mind."

I fear that the writer of your letter must have been rather unfortunate in his experience with railroad men on highway work, and one cannot help wondering what kind of railroad men he had to deal with. I do not know of any branch of engineering where men can make money go further or make a dollar earn any more interest than the first-class railroad locating engineer, either on railway or highway location.

Is there any set of engineers who are oftener required to break their long grade lines, use heavier rates of grade, adopt sharper curves and otherwise lower their ideal standard of excellence in order to get their line through for the funds available than the railroad locating engineer? If he can do this on a railroad, he can also do it on a highway.

I do not wish to be understood as harshly criticizing men who have not had the benefit of railroad experience. Many of these men have done and are doing the highest class of highway work. When the man with the nonrailway experience understands what is wanted *and how*, he is as efficient as the railway man.

It is undoubtedly true that all railroad men are not successful highway locating engineers; but I believe that, as a rule, the railroad locating engineer will make better road locations than men from any other school of practice. I also believe that the number of unjustified sharp curves and the heavy grades found in easy country, which have been laid out by nonrailroad engineers, will greatly outnumber the unwarranted light grades and too easy curves in mountainous country for which men of the Wellington school can be held responsible.

W. H. WAUGH.
Senior Supervising Engineer,
Bureau of Public Works.

Manila, P. I., Sept. 18, 1914.

The New York Rapid Transit Railway Extensions*

By F. Lavis†

V--Ventilation, Drainage and Waterproofing

Ventilation

Every effort has been made to so design the new subways, that the excessive heating which occurs at times in the summer in the present subway may be avoided. The tracks are to be divided so that trains going in one direction will be in a separate tube or tunnel from those going the opposite way; by this means it is expected to utilize the movements of the trains (the so called piston action where there is only one track in a single tube) to push the air ahead and out through the openings which are provided for this purpose.

The original subway is completely surrounded by an envelope of waterproofing, and it has been thought that this has prevented the dissipation of some of the heat generated by the motors, brakes, friction, etc., into the ground surrounding the structure. On the new lines waterproofing will generally only be used where actually necessary to keep out water, that is, below the ground-water line, in earth, and on the roof.

Openings in the roof of the tunnel, with sidewalk gratings, are provided over the station platforms, and generally one about half way between each station and one at each end of the stations on the side toward the approaching train, these latter being expected to take care of most of the draft caused by the train, instead of allowing it to create a current at the platform and up the stairways. The general form of these openings, and the details of their construction are shown in Fig. 22, and a typical arrangement of location in Fig. 21 (7th Ave., 17th to 24th St.). The dimensions and numbers of these openings have been so fixed that it is expected that the current of air issuing through the gratings in the sidewalk will be hardly noticeable to pedestrians.

Fan chambers, which are all arranged so that they may be also used as emergency exits to the streets, are provided, one about midway between each station. These are so arranged that they will draw the air from the tunnel at points intermediate between the stations and force it out through the gratings already described, thus, of course, drawing fresh air in at the stations. It is expected that the openings above combined with the action of the trains will ordinarily provide sufficient ventilation, the fans being used only occasionally when circumstances require.

The piston action of the trains in the single-track tube of the Hudson & Manhattan R.R. has been reasonably efficacious in promoting efficient ventilation, but except on the Fourth Ave., Brooklyn, line, where there is a parked space in the center of the street and where walls are provided between each track, it was not considered practicable to divide all the tracks of the new four-track lines so that each would be in a separate tube, on account of the difficulty of providing stations for the center tracks. It would be impractical, of course, to provide openings in the roadway of the streets, and in order that the openings in the sidewalks might be used, the center wall only was built dividing the traffic going in opposite directions, but leaving the two tracks on one side in the one space. If this does not produce the required movement of the air, that is, actual propelling movement, not mere stirring up as in the present subway, the fans must be utilized to supplement it. Openings about 2 ft. wide and 8 ft. high are provided at every 10 ft. in the center wall as a means of communication between the two sides, and as refuge niches, and these may tend to reduce the piston effect to some small extent.

Although this arrangement in the four-track section will reduce somewhat the positive piston action of the trains, it will be beneficial to the extent that it will tend to reduce the air resistance, which has been shown* to be by no means a negligible factor in cost of operation in single-track tubes, though this cost may be offset by the benefits of more efficient ventilation.

The actual effect of all these different items and of the size of the cross-section both on the efficiency of ventilation, as well as the cost of operation, is something of which little is actually known, but in view of the enormous expenditures which are being made and which undoubtedly will continue to be made in underground railways for rapid transit, in subaqueous tunnels, etc., it is hoped that further experiments along the lines of those already referred to* and others of like nature may be continued.

As will be seen by the diagrams, the object of the design of the openings has been to provide at the track level a space into which the air pushed ahead of the train may expand and be detained, instead of being pushed by, and then provide an opening above through which it may escape to the surface, there being apparently little reason to doubt the efficacy of this proposed scheme.

Drainage and Waterproofing

In the general clauses of the specifications it is stated that "it is the very essence of these specifications to secure a railroad structure underground which shall be free from the percolation of ground or outside water. The mixing and placing of the concrete and the placing and protection of the waterproofing shall be with this end in view."

"In general, waterproofing of the structure will be limited to the roof and sidewalls at the stations and over the roof between stations, and to those surfaces near ground water or mean high water if ground-water level is found for any reason to be below mean high water. At other places free drainage shall be provided by pipe drain, hollow tile or broken stone."

The specifications provide for the use of fabric waterproofing, laid in hot pitch or asphalt, and in from three to six thicknesses or plies, and for brick or hollow tile, laid in pitch or asphalt mastic. The latter to contain "one-

third pure bitumen, and sand and cement or lime dust in proportions governed by local requirements and weather conditions."

At temperatures of 50° to 70°, the proportions used are usually one-third asphalt, one-third cement, one-third sand; in colder weather the proportion of asphalt is in-

protected from injury by barricades or otherwise, if necessary until thoroughly set.

It is intended to obtain concrete impervious to water; the concrete shall be mixed and deposited with this end in view, and on the roof of the railroad, if waterproofing is not used, the top surface of the concrete shall be carefully troweled as may be directed in order to add to its imperviousness.

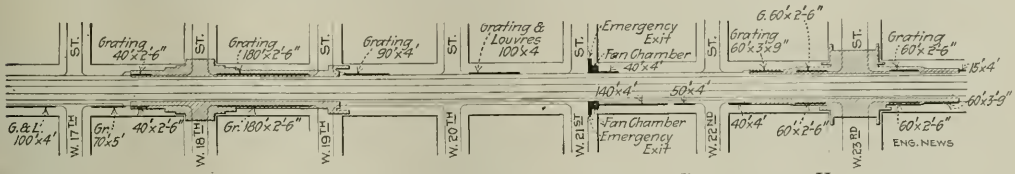

FIG. 21. PLAN OF PORTION OF SEVENTH AVE. SUBWAY, SHOWING PROVISION FOR VENTILATION

creased as required up to a maximum of 60%, though 50% is seldom exceeded. Lime dust is apparently not used in place of the cement, as it appears to require a larger proportion of asphalt to make it workable.

The fabric waterproofing is generally used on the roof or other horizontal surfaces where it may be required, and the brick in mastic on the sidewalls or on any vertical

Reference has already been made to the fact that on account of the supposed influence of the waterproofing envelope inclosing the present subway, in retaining the heat, that waterproofing is only carried out in the new lines where the evident necessity shows the need of protection to keep the structure reasonably dry. Much greater reliance is being placed on the provision of free

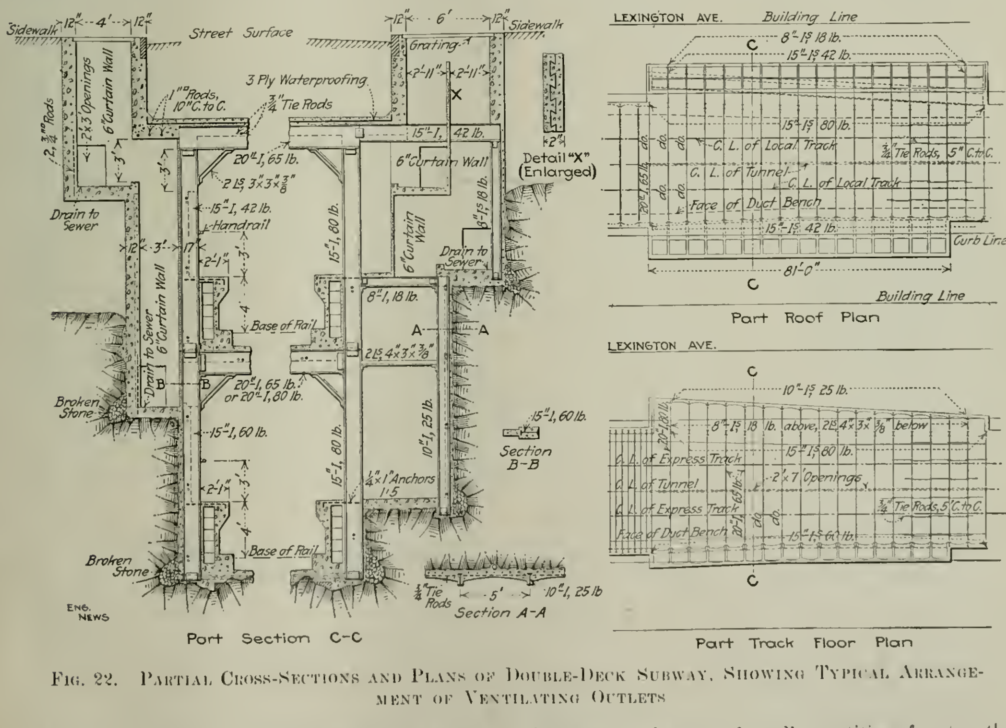

FIG. 22. PARTIAL CROSS-SECTIONS AND PLANS OF DOUBLE-DECK SUBWAY, SHOWING TYPICAL ARRANGEMENT OF VENTILATING OUTLETS

surfaces and under the floor when required there. At stations brick and mastic are used over the roof.

In the concrete specifications, the following clauses apply to the waterproofing:

The proportions of cement and sand and stone (or gravel) used in making protective concrete outside of waterproofing lines on sides and roof, shall be as follows: 1 part of cement, 4 parts of sand and 8 parts of stone.

Concrete to which waterproofing is to be applied shall be made smooth at the time of laying and shall be carefully

drainage to take care of small quantities of water, than has been done heretofore, this being in line with recent experience.

The question of waterproofing tunnels is comparatively modern and its importance is due principally to the development of electric traction and of the numerous underground lines for urban rapid transit. On that section of the Pennsylvania Railroad's New York tunnels,

which passes under the Bergen Hill* on the Jersey side of the Hudson River, and where there was a considerable seepage of ground water, the ample and careful provision of free drainage, without the general use of waterproofing has resulted in a remarkably dry structure.

On all the new subway lines, drain pipes are laid in the floor (under the center of each track) which lead to sumps at pump chambers, from which the drainage is discharged by automatic electric pumps into convenient sewers.

These floor drains have grating openings in the concrete floor every 50 ft. and the floor grades are arranged (irrespective of the track grades) so that there is a summit between each grating (in the case of steep grades 2 or 3%, the summit is just below the grating). 4-in. pipes lead to these center drains from the sides, and, if necessary, part or all the way up, to take care of any seepage there may be. In the case of the Lexington Avenue rock tunnels, these side drain pipes generally reach up to the bottom of the loose rock packing over the roof. See Figs. 12 and 14.

Speaking generally, there are two typical methods of waterproofing. The first where the structure is in earth, where the water level (mean high water or ground water) is above the bottom of the structure. In these cases the waterproofing is carried across the bottom and up the sides to about 2 ft. above the level of the water. See Fig. 15. This drawing also shows the waterproofing carried over the roof, as the section is taken at a station.

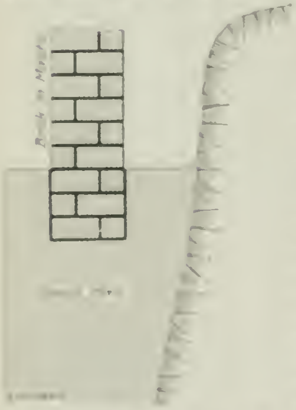

FIG. 24. EXAMPLE OF WATERPROOFED STRUCTURE IN ROCK WITH BRICK WALL LAID IN MASTIC

The second where the structure is partly in rock and where the water level is above the rock. In these cases the waterproofing is carried from a point 2 ft. above the water level to the rock or more commonly sealed into a trench in the sand wall, as shown by the sketch, Fig. 23.

When the water level is below the top of the rock, waterproofing is not generally used except over the roof (see Fig. 15), and in the case of the Lexington Ave. tunnels, even this is omitted.

[illegible]

[illegible]

above the water level, no waterproofing at all is used; on the other hand, just above this point, at about 102nd St., though the structure is wholly in rock, the water level is about 10 ft. above the bottom of the structure and the brick in mastic is, therefore, carried down below the floor at the sides, and the top is covered with 1 ply of fabric and two layers of brick in mastic. Burlap coated with an asphalt compound is generally used for the fabric, but where there is water, as in the bottom under the floor or in depressed bays, etc., one layer of felt is used first.

At stations the waterproofing (3-ply fabric or 1-ply and two layers of brick in mastic) is carried over the roof and down the sides to below the track level, in order to prevent any damage to the decorations, as well as to protect the offices and passengers.

When the floor is to be waterproofed, a 6-in. concrete base is laid in the bottom of the excavation, and two layers of brick laid flat in mastic laid on this; at the sides, if the sheeting is to be left, the two courses of brick in mastic are generally laid right against it, otherwise, where the sides require waterproofing, the steel is first erected, then a hollow-tile or concrete-sand wall is built behind it, on which the waterproofing fabric is hung and then the concrete sidewalls are built. Loose rock is packed behind the hollow tile as it is built up.

In many cases the protection wall of 4-in. hollow tile, or a concrete sand wall is built, then the steel is erected before the brick in mastic is laid up. The steel columns then act as braces for the rough board forms necessary to support this latter until the mastic hardens. These boards are usually painted with a good thick coat of cement grout to prevent their sticking to the mastic, the grout sticks to the mastic and the boards are easily removed.

An inspection of the various bids made up to the present time shows the general average prices for the above classes of work on the contracts awarded to be approximately as follows:

Waterproofing, 1 ply per sq. yd.	[illegible] to [illegible]
Waterproofing, 2 ply per sq. yd.	[illegible] to [illegible]
Waterproofing, 3 ply per sq. yd.	1 [illegible] to 1 [illegible]
Waterproofing, 4 ply per sq. yd.	1 [illegible] to 1 [illegible]
Waterproofing, 5 ply per sq. yd.	1 [illegible]5 to 1 [illegible]
Waterproofing, 6 ply per sq. yd.	1 [illegible] to 2 [illegible]
Brick in mastic, per cu. yd.	[illegible] to 38.00
Vitrified drain pipes, 4 in. per lin. ft.	$[illegible]
Vitrified drain pipes, 6 in. per lin. ft.	[illegible]
Vitrified drain pipes, 8 in. per lin. ft.	[illegible]
Vitrified drain pipes, 10 in. per lin. ft.	[illegible]
Vitrified drain pipes, 12 in. per lin. ft.	1 [illegible]
Cast-iron drain pipes, 4 in. per lin. ft.	$0.75 to $1 [illegible]
Cast-iron drain pipes, 6 in. per lin. ft.	1 [illegible] to 1 [illegible]

Concrete Roads in Wayne County, Mich.

The eighth annual report of the Road Commissioners of Wayne County, Mich., just issued, is of interest to all who are following the progress of concrete-road construction. That these are numerous is indicated by the statement that hardly a day has passed throughout the year without the visit to Wayne County of a delegation from some part of the United States and Canada to examine the concrete roads.

The county now has over 100 miles of concrete road, some of it in its sixth year of service. The Commissioners say that as these roads are without the semblance of a rut and not a single 25-ft. section has been taken up and replaced since its beginning, the adoption of the concrete road as the standard type for Wayne County is justified.

*The Bergen Hill Tunnels of the P. R.R. [illegible]

The success of the Wayne County roads is further evidenced by the adoption of concrete for roads elsewhere in the vicinity. The City of Detroit will put under contract during the present year over 139,000 sq.yd. of concrete paving for streets and alleys. A number of cities and villages near Detroit and across the river in Canada are laying large amounts of concrete road and street paving.

The Commission announces that it has abandoned the construction of roads having a width of concrete of less than 15 ft. and 24 ft. with the shoulders. A number of its existing concrete roads are only 12 ft. wide; but it has been found that when these narrow roads are opened, the amount of traffic attracted to them makes it desirable to have a greater width. In other respects the specifications used last year are unchanged. The principal endeavor now in the road work is to secure a surface even and level, free from wavy depressions and irregularities.

A notable feature of the Wayne County road work is that it is practically all done by day's work by the Commission's own forces, there being at times some 600 to 800 men employed.

The board alludes to the difficulty experienced in financing the work by the sale of county bonds which bear only 4% interest. It became necessary in order to sell the bonds, to appeal to the public spirit of local financiers. Of the entire issue sold last year of $368,000, the Ford Motor Co. took $100,000.

A large part of the cost of concrete-road construction is hauling the material onto the work. The Wayne County plant includes an industrial railway outfit, 100 to 150 teams and wagons and eight traction outfits. The industrial railway is of 2-ft. gage with portable track in 15-ft. lengths. The rolling stock consists of a 7-ton 30-hp. locomotive, 60 steel dump cars 1½ yd. capacity, and five 16-ft. flat cars. The locomotive will haul 30 loaded cars.

Where the industrial railway is not available, material is hauled by teams and tractors. The teams work economically on short hauls, but are often difficult to secure in the road-building season at reasonable prices. Road rollers are largely used for traction, hauling wagons carrying a seven-ton load. Over earth roads this is about all one tractor can haul. Where, however, a concrete road is available for hauling, six wagons carrying 42 tons of material are made up into a train and hauled by one ten-ton roller.

A large amount of water is required in making the concrete road, not only for the concrete but to puddle the subgrade in advance of the concrete laying. It has been found economical to lay a 2-in. pipe along the road from the nearest source of supply and pump the water by gasoline engine or electric motor. In some cases water has been delivered in that way over ten miles from the pumping station.

Curing of the concrete after laying is an important matter. Following the laying of the concrete, it is covered with 2 in. of sand or loose soil, and this is sprinkled daily for ten days. The road is not opened to traffic, however, until three to six weeks have elapsed, according to the season of the year. The shoulders of the road are built of crushed stone or gravel from 3 in. to 7 in. thick and 3 to 4 ft. wide on each side of the concrete.

An interesting section of the report is that on maintenance, as critics of concrete roads have maintained that the cost of keeping them in repair will be excessive. The report, however, contains no separate figures as to the cost of maintaining concrete roads. The total amount expended for repairs on all county roads during the year was $23,393, a saving of $7140 over 1912. This total, however, includes the maintenance of all the gravel and macadam roads in the county as well as the concrete roads; oiling and heavy repairs on the gravel roads and dragging after rain, cleaning of ditches and culverts, and painting of bridges and guard rails, and such necessary work as cutting brush, weeds, etc., and cleaning ditches. The method of repairing cracks or spalling at the joints of concrete roads is the same that has been used in previous years, viz., filling the crack with hot Tarvia of a grade melting at about 80° F., and covering the top with dry sand.

Annual Meeting of the Northwestern Road Congress

The Northwestern Road Congress, organized some months ago, held its first annual meeting at the municipal Auditorium at Milwaukee, Wis., on Oct. 28-31. The attendance consisted largely of township and county officials.

Prof. T. R. Agg (Iowa State University), was President of the Congress. Mr. Hazlewood, Vice-President of the Congress (and Chairman of the Wisconsin Highway Commission), spoke strongly of the necessity of keeping the work and appointments free from political influence.

A paper by Prof. Brindley (Iowa State University) on "The Functions of the State and the County in Highway Administration" had as its keynote the absolute necessity of fixed responsibility and competent supervision to insure good work and economical use of the public funds. He advocated putting the care of secondary roads (representing 75% of the total) in the hands of a responsible commissioner for each township, and the main roads under a county enginer, with a State Commission and enginer in general supervisory charge over all roads, bridges and culverts.

A paper on "The Authority and Responsibility of the County Engineer or Commissioner" was read by Grover Blunt, County Engineer of Fayette Co. (Iowa), and one on "The Inspection of State-Aid Road Work," by John T. McDonaghey, Chief Inspector of the Wisconsin Highway Commission. The latter outlined the system employed in Wisconsin, which was reviewed in Engineering News, Oct. 15. A paper on "Day Labor or Contract Systems for Road Building," by A. R. Hirst, State Highway Engineer of Wisconsin, was very strongly in favor of the former system, as being the more economical and efficient, except for large jobs or for work requiring more special equipment than it would pay the local authorities to own. He stated that in Wisconsin, contract work is rarely done within the contract price, while the engineers of the highway commission are getting work done better and at less cost than it could be done by contract.

In regard to legislation, a paper on "Practical State-Aid Policies," by Mr. Gash (President of the Illinois Highway Commission), reviewed the recent revision of the road laws in Illinois. In the discussion, Mr. Mullen, of the Minnesota Highway Commission, discussed the ques-

and whether the State should undertake construction or merely render financial and technical assistance to counties and townships. In Minnesota the latter system is employed with the important feature that it provides for continuous maintenance of all roads.

A paper by John N. Carlisle (State Commissioner of Highways of New York) was unfavorable to the special-assessment method for financing county road work.

A set of six papers dealt with the technical side of road construction as follows: "Brick Roads," by Mr. McCleary, Engineer of Cuyahoga Co., Ohio; "Concrete Roads," by Mr. Knelling, Highway Engineer of Milwaukee County; "Bituminous Concrete Paving," by Mr. Simmons, Commissioner of Public Works, of Milwaukee; "Gravel and Macadam Roads," by Prof. Agg, Iowa State University; "Earth Roads," by Mr. Sargent, District Engineer of the Wisconsin Highway Commission, and "Highway Bridges and Culverts," by Prof. Marston, Iowa Highway Commission.

Leakage in the Moodna Tunnel of the Catskill Aqueduct near the Hudson River Crossing

Bids are now being called for in our advertising columns, to be opened on Nov. 10, for driving a shaft some 400 ft. deep and a section of tunnel about 900 ft. long to supplement the existing Catskill Aqueduct on the west shore of the Hudson River at Storm King, where the aqueduct approaches the river.

The circumstances which have led to the undertaking of this work are of considerable engineering interest. It will be recalled that the Catskill Aqueduct, from the Ashokan Reservoir in the Catskills to the high level distributing reservoir just north of New York City, is composed of cut-and-cover concrete conduit, tunnels at hydraulic gradient through hills and pressure tunnels deep in solid rock beneath certain major valleys. Under New York City itself also the distribution is to be by a deep pressure tunnel in the rock.

It is well understood, of course, that pressure-tunnel construction can be successfully used only where the rock is solid and unyielding. Concrete lining is put in merely to close possible interstices in the rock, to aid in making the rock more water-tight by grouting and to furnish a smooth surface for the water to flow over. The enormous bursting pressure exerted by the water in this large aqueduct, 14 ft. in diameter, under a head of several hundred feet, would, of course, rupture any concrete lining which could be placed were it not for the resistance of the solid rock back of the lining.

The Catskill Aqueduct passes under the Hudson River at Storm King through a rock tunnel driven at a depth of 1100 ft. below the water surface. The opposite ends of this tunnel connect with shafts reaching to the surface. At the shaft on the west side of the river, at a depth of 300 ft. below the water level, or about 270 ft. from the surface of the ground, connection is made with a tunnel leading to the westward, the so-called Moodna pressure tunnel, driven through the solid rock under the northern toe of Storm King Mountain.

The West shaft of the Hudson siphon (like the East shaft) was sunk by the city as a test shaft to gain information leading to the construction of the siphon. Having developed unusually sound and water-tight rock, it was believed worth while to use this shaft as a part of the siphon, thus saving the expense of another shaft farther west and the consequent additional step in the profile of the tunnel.

The rock was carefully inspected as the shaft was sunk and to all appearances it was, in the judgment of the engineers, stable and unyielding, and unusually favorable material for a water-tight conduit.

The lining of this section of the tunnel was completed last winter, and it was later subjected to the full designed water pressure, with the result that a considerable volume of leakage developed beneath the West shaft and the next shaft, 520 ft. west of it. When the tunnel was pumped out and inspected, it was found that notwithstanding the fact that the minimum depth of rock cover was, as stated above, 270 ft., there had been a slight yielding of the rock at certain points with the result that the concrete lining had been cracked, permitting water to escape. These cracks were very small, the widest, we are informed, being only one-eighth of an inch in width, but under the enormous head, even these small cracks permitted the escape of a large quantity of water, although only a very small percentage of the aqueduct's capacity. No evidence whatever of the movement of the rock is detectable at the surface of the ground.

When the tunnel is once put in operation and becomes a reliance of the city for its water supply, it must be dependable. Moreover, since the statistics of growing water consumption in New York show that the entire Catskill supply may be needed by the city at no distant date, every means possible must be adopted to reduce the amount of leakage from the tunnel.

Under these conditions it was deemed to be desirable to abandon the use of that part of the West shaft of the Hudson River siphon nearest the surface and of a small part of the Moodna pressure tunnel connecting with it. The work on which bids are now called for involves going back 900 ft. farther into the solid rock of Storm King Mountain along the Moodna pressure tunnel, making at that point a shaft 400 ft. in depth, and from its bottom driving a horizontal tunnel 900 ft. long to connect with the deep shaft connecting with the tunnel under the Hudson. It is believed that this will carry the aqueduct so far below the surface that no movement of the rock under the heavy hydrostatic pressure need be feared.

On account of the possibility of shortage in the Croton supply occurring during the next twelve months, should the drought of 1914 continue, the contract calls for pushing the work with the utmost possible speed. One year's time is the amount allowed for the work. However, in case an emergency should arise during the construction of the tunnel compelling the putting into use of the Catskill aqueduct, it would be possible temporarily to cease the work on the new tunnel and shaft and use the aqueduct as now completed, the contractor of course being obliged to suspend his work until the emergency was over and the tunnel could again be pumped out.

Readers desiring a further description of the work previously done at the Hudson River crossing may refer to the extended article on this work by Alfred D. Flinn, Deputy Chief Engineer of the Board of Water Supply, published in our issue of Mar. 23, 1911.

Collapse of Reinforced-Concrete Arcade, Hippodrome Building, Youngstown, O.

A section of a new arcade being built in connection with the new Hippodrome building, to run from Federal to Commerce St., in Youngstown, Ohio, collapsed during construction on Oct. 26, and killed three of the workmen who were in the lower part of the building, and injured three more. Fortunately, a great number of workmen had left the collapsed area just previous to the failure, so a much greater disaster was averted.

The building comprises a theater section of steel construction, with an adjoining arcade building entirely of reinforced concrete. This arcade had a basement and was partly one and partly two other stories in height but at the area of failure had two floors and the roof. It is of straight column-and-beam construction with columns spaced 20 ft. along the narrow dimension of the arcade and 15 ft. 3 in. along the long dimension. The collapsed portion comprised the whole three stories, throughout an area of 40 ft. wide and 107 ft. long, that is, two transverse panels and six longitudinal panels. The columns were square in section, 16x16 for the interior and 14x14 for the outside. They were reinforced with straight rods at the corners. The beams, 20 ft. in span, were 13x16 in. section, reinforced according to the Kahn system. The floors were of rib construction, according to the "Floretyle" system of the Trussed Concrete Steel Co. The floors were designed for 125 lb. per sq.ft. load.

The basement columns were cast on Sept. 22, the first-floor slab Sept. 23, the second-floor slab Oct. 2, and the roof Oct. 24; thus at the time of collapse the age of the concrete varied from two days for the roof to 34 days for the basement columns, with at least 24 days age for all the concrete below the second floor. During the time since this concrete has been laid no particularly cold weather had been experienced.

The precise nature of the collapse has not as yet been brought out. Reports have been circulated that the struts supporting the first floor were removed just prior to the accident, to allow some plumbers to get into the building with their work, but these reports have been strenuously denied by all those concerned with the building. Eye witnesses are few, so it has not yet been brought out whether the first floor failed first and carried down with it the upper portion of the building, or whether the roof collapsed

Collapsed Portion of Reinforced-Concrete Arcade, Hippodrome Building, Youngstown, Ohio

[illegible] broke down the lower floors. As the [illegible] shows, the collapse was complete. The [illegible] at the columns and at the walls [illegible], with one exception, were thrown completely down. The stump of one column still stands.

The [illegible] was all tested by a recognized laboratory and passed the regular standard specifications. The sand and gravel were tested by the city building inspector. It is stated that the loam in the aggregate did not exceed [illegible]. The concrete seems to be all right.

The building was owned by the Youngstown Hippodrome Co. and was designed by Knox & Elliott, architects, of Cleveland. The contractor is the George A. Fuller Co.

NEWS NOTES

A Large Dry Kiln Collapsed at the mills of the [illegible] Lumber & Kiln Co., Samson, Ala., Oct. 27. Four men were killed and 50 severely injured.

A Water Front Fire at San Pedro, Calif., on the morning of Oct. 2[illegible] destroyed the wharves and warehouses of the Crescent Wharf & Warehouse Co., the East San Pedro Cannery and the depot of the Salt Lake, Los Angeles & San Pedro Ry.

The Falling of a Terra-Cotta Cornice on the new building under erection in Jamaica, N. Y., for a substation of the New York & Queens Electric Light & Power Co., Oct. 26, caused the death of three workmen and injuries to about twelve others.

A Section of 6-Ft. Brick Storm Sewer Collapsed, Oct. 1, at Freeport, Ill. The collapse is laid to a want of lateral support caused by excavating for a near-by building. The contractor for the building excavation has been held responsible and will make the necessary repairs.

A Disastrous Mine Explosion occurred Oct. 2[illegible] at the mine of the Franklin Coal & Coke Co., Royalton, Ill., in which about 51 men lost their lives. The explosion is reported to have been due to gas ignited by a miners' lamp. The explosion was followed by a fire and apparently by a second explosion.

Exhibition of Street Cleaning Apparatus—The exhibition to be held in New York City under the auspices of the Street Cleaning Department has been again postponed to Nov. 23-2[illegible]. The exhibition will be held in the Armory of the First Regiment of Field Artillery, Broadway and 68th St. J. T. Fetherston is Commissioner of Street Cleaning.

Another Big Pier Fire, Brooklyn, N. Y.—A new 12[illegible]-ft. [illegible] pier of the [illegible] Line, at the foot of [illegible] St., Brooklyn, N. Y., was badly damaged by a fire of [illegible]. Damage to structure and contents is [illegible] at $[illegible]. Quantities of inflammable freight [illegible] on the pier made the fire [illegible].

A Fast Train Was Derailed on the Chesapeake & Ohio Ry., Oct. [illegible], at [illegible], W. Va. The [illegible] broke in two and the [illegible] [illegible]

Three Fires in or Near Reinforced-Concrete Buildings, [illegible]

[illegible]

[illegible] explosion was of such violence as to blow out a brick wall on the south side of the building on the upper two floors, though no damage was done to the structural part of the building. The fire on the sixth floor started where two carloads of matches were stored. These naturally burned intensely, the fire keeping up for about three hours at a temperature estimated at 1700° F. The roof above the floor was of the tile and concrete beam system. The bottoms of some of the tile were destroyed but the roof remained intact. On a part of the second floor brooms and paper bags were stored to the height of the ceiling, the floor above being loaded with canned goods weighing about 300 lb. per sq. ft. This floor was not seriously damaged by the fire nor did it show any deflection. The damage to the stock amounted to about $200,000, but the building was repaired at very little expense.

On May 16, 1914, a severe fire occurred in the First Christian Church annex, Kansas City, Mo. The first and second floors of the annex were of reinforced concrete. The upper three floors were cast-iron columns, steel beams and wood joist. The building was in course of construction at the time of the fire. The upper three floors of the annex and the church itself were destroyed by the fire, but the concrete part of the building was not seriously damaged. The architects state that after a thorough examination they note that "the reinforced-concrete slabs and columns in the new addition had come through without a scar."

Stone Production in the United States broke all records in 1913, reaching a total value of $83,732,995, according to E. F. Burchard, of the U. S. Geological Survey. These figures show an increase of 7% over the value of the output for 1912, which in its turn broke all records of preceding years. Of the different kinds of stone produced, the largest increase in value was shown by trap rock, which was 23% greater than in 1912.

Some of the Old Wooden Sewers in Boston, which were described in "Engineering News," of Sept. 10, 1914, will be replaced by modern sewers during the coming winter. The work will be done in the vicinity of the post office and will be undertaken this winter not only because of the need of reconstruction but also to afford work to some of the unemployed. It is estimated that work to the value of about $15[illegible],000 will be done.

The First Subway in New York City was ten years old on Oct. 27, 1914. The first section of it to be placed in operation was formally opened on Oct. 27, 1904, when the then Mayor, George B. McClellan, opened the throttle on the first of three special trains carrying city and company officials and their guests. From the date of this opening to the close of the last fiscal year, June 30, 1914, the subway has carried 2,33[illegible],101,305 passengers, an average of more than 233,0[illegible] passengers per annum. (The present week-day number is approximately one million.) The total operating revenue for the same period was $1[illegible], and the operating expenses and taxes $49,[illegible]. The rental paid to the City amounted to $[illegible].

The New Central Station at Memphis, Tenn., was opened for traffic in October. It is owned by the Illinois Central R.R. and is used also by the Rock Island Lines, the St. Louis & San Francisco Ry. and the Yazoo & Mississippi Ry. There are [illegible] through tracks and [illegible] stub tracks, the latter being mainly for the three last named roads, whose trains do not run [illegible] of Memphis. The station building has eight stories, the passenger facilities being mainly on the second or track floor, and the five upper floors being for railway offices. The track elevation work in connection with the new station [illegible] six street crossings, and the tracks are carried over the streets by [illegible] [illegible] Illinois Central R.R. [illegible] "Engineering News," Sept. [illegible], 1914.

The Smallest Central Electric Station [illegible] at [illegible], Wis. The town has a population of [illegible] [illegible] street lamps. [illegible]

The Lowering of Jones' Falls in Baltimore, Md., was officially completed on Oct. 2[illegible], when Mayor Preston set off the [illegible] which broke down a barrier and diverted the water from the [illegible] into the 2[illegible]-ft. tunnel and thence into the [illegible]. The work of [illegible] was described in "Engineering News," July 3, 1913, p. 2. Jones' Falls, an open stream running through the heart of Baltimore, for years [illegible]

street and house drainage and constituted a nuisance to sight and smell. As a part of the new sewer system of the city, now fast approaching completion, the creek was covered from its mouth near the river to near Biddle St., a distance of 5500 ft., with a three-way box conduit of reinforced concrete. From Biddle St. to Mt. Royal Ave. the stream was diverted through a 29-ft. tunnel which takes the stream from the old bed and connects down-stream with the conduit. The covering, together with a reinforced concrete viaduct at the upper end, form a low-grade street connecting the railway stations and wharves, which before had been connected by high-grade streets only.

The work was under the direction of Calvin W. Hendrick, Chief Engineer of the Sewerage Commission.

The New Water-Intake Tunnel at Milwaukee, Wis., had been driven 3017 ft. on Oct. 30, while the total length is 4000 ft. to the new crib, which has already been sunk in place. Following the cave-in and entrance of water described in our issue of Oct. 29, the grade has been lowered slightly to keep the work in solid shale rock. After the accident, it was suggested that the air lock (near the shore shaft) should be replaced by one nearer the heading, but on investigation this was considered unnecessary. A bulkhead was built, however, at about 2950 ft. from the shaft. Air pressure was used only for a short time, and the work is again progressing with the air lock out of service. The work for 1915 will include the land tunnel running southwest from the new shore shaft to the present pumping station, so that, in case of necessity, water can be taken by the new crib and intake tunnel. The intention, however, is not to utilize the new intake tunnel until the pipe lines have been laid from the crib into water about 60 ft. deep. In 1916, work will be commenced on a shore tunnel running due west from the intake tunnel to a new pumping station near the river. The new intake tunnel and its connections were described in "Engineering News," June 18, 1914.

An Injunction Against the Pollution of the Delaware River by the sewage of Phillipsburg, N. J., must be issued, according to a decision recently made by the Chancery Court in the State Board of Health vs. Phillipsburg. The major part of the decision, which is lengthy, disposes of the contentions of the defendants that (1) the power over sewage disposal originally vested in the old State Sewerage Commission was not legally transferred to the State Board of Health, a few years ago; and (2) that the power mentioned did not extend to the potable waters of the Delaware River. The court also declared that "it is idle for the defendant to ask of what avail it would be to stop" it from discharging sewage into the Delaware when Easton, directly opposite, is polluting the river. In addition, the court held, in effect, that threatened pollution would be sufficient cause for the injunction, even though actual pollution could not be proved. The injunction will carry it with the necessity for sewage disposal by Phillipsburg in a manner to be approved by the State Board of Health. An appeal to the Court of Errors and Appeals is expected. We are indebted to R. B. Fitz Randolph, Chief of the Division of Food, Drugs, Sewerage and Water of the State Board of Health of New Jersey, for a copy of the decision.

A Practical Demonstration of Fireproof Residence Construction was given by Edward F. Croker, former Chief of the New York City Fire Department, now President of the Croker Fireproof Construction Co., New York City, at his home at Long Beach, Long Island, N. Y., Oct. 30. The house is constructed of hollow tile and stucco, with steel-frame floors and partitions, metal window sashes and wire-glass windows, steel doors and trim and asbestos-plastered walls. The floors are of a material known as "konpolite." The ceilings, like the walls, are hollow tile covered with asbestos plaster. The demonstration consisted in settling a fire in one of the sleeping rooms, full of furniture and furnishings, helped out by two gallons of gasoline, shutting the door and allowing the fire to burn itself out. No damage was done the house or the walls of the room. As guests of the occasion Mr. Croker had many fire prevention engineers and experts and an illustrated report is to be made. Mr. Croker claims this is the first and only actual fireproof residence in this country. His object, which seems to have been fully accomplished, is stated as follows:

My experience, both as a fireman in the ranks and as a Chief of the Fire Department of the City of New York, covering a period of 27 years, convinced me it was both possible and feasible for the average owner of residences, both private and apartment houses (and particularly large residences in the suburban districts), to construct at very little additional expense, if any, an absolutely fireproof home in every sense of the word; in fact, a residence whereby shutting the door of each room at night, one could feel safe that, even if a fire did occur, it would be confined to the room in which it originated, permitting the occupants of the other rooms to sleep in absolute security.

PERSONALS

Mr. T. R. Quay has resigned as Heating and Ventilating Engineer of the city building inspection department of Cleveland, Ohio.

Mr. Thane R. Brown, Assoc. Am. Soc. C. E., for 20 years with the Wisconsin Bridge & Iron Co., Milwaukee, Wis., has been promoted to be Chief Draftsman.

Col. John Biddle, M. Am. Soc. C. E., Corps of Engineers, U. S. A., has been detailed as a military observer with the Austrian Army. He has been on temporary duty with the Chief of Engineers at Washington, D. C.

Mr. W. J. Dyer, M. Am. Soc. M. E., Assistant Manager of the Honolulu Iron Works Co., Honolulu, H. I., has resigned to engage in private practice, with offices in the Stagenwald Bldg., Honolulu.

Mr. J. M. Keller, M. Am. Soc. M. E., until recently Chief Engineer of the Otis Steel Co., Cleveland, Ohio, has been appointed to the newly created position of Chief Engineer of the National Carbon Co., also of Cleveland.

Mr. John R. Haswell, Jun. Am. Soc. C. E., Drainage Engineer, United States Department of Agriculture, has been transferred to Baltimore, Md., to represent the drainage division of Maryland, Delaware, New Jersey, Pennsylvania and New York.

Mr. F. C. Herrmann, M. Am. Soc. C. E., Chief Engineer of the Spring Valley Water Co., San Francisco, Calif., has resigned to engage in private practice as a Consulting Engineer, specializing in hydraulic engineering, with offices in the Merchant's Exchange Bldg., San Francisco.

Mr. William T. Dougan, M. Am. Soc. C. E., Engineer of Maintenance-of-way of the New York Rys., resigned Oct. 1 to engage in private practice. He graduated from Union College in 1892 and his first experience was as Assistant to the Chief Engineer on the construction of the Fonda, Johnstown & Gloversville R.R. Later he was Chief Engineer on construction of the Herkimer, Mohawk, Ilion & Frankfort Electric R.R. He entered the service of the Metropolitan Street Ry., New York City, in 1897.

Mr. Hugh C. Mitchell, recently Engineer in charge of the Topographic Survey of Cincinnati, Ohio, which was described in "Engineering News," Apr. 3, 1913, has become associated with the firm of Brown & Clarkson, Topographic Engineers, Star Building, Washington, D. C. Mr. Mitchell was for many years an officer of the United States Coast & Geodetic Survey and in coöperation with the firm of Brown & Clarkson will specialize in geodetic survey work and engineering topographic surveys of cities, borough, counties and large land divisions.

Mr. Joseph A. Kitts, Assoc. M. Am. Soc. C. E., has resigned from the service of the Panama Canal and returned to the United States. Mr. Kitts entered the service of the Isthmian Canal Commission, in 1905, when a student on leave of absence from the University of California. He was successively with the engineering staffs of the Bureau of Machinery and Equipment, the Panama R.R. and the Municipal Department. Returning to San Francisco after the fire of 1906 he was engaged on reconstruction work. After completing his studies at University of California, he was reappointed to the Canal Service in 1910, and has been engaged as Principal Assistant in charge of surveys for the construction of the Toro Point Breakwater; Engineer in charge of surveys for the excavation of Mindi cut, installation of machinery, lock gates, towing and return railways, Gatun locks, and construction of the Pacific terminal shops.

Mr. Frank M. Williams, M. Am. Soc. C. E., former State Engineer of New York, has been again elected State Engineer on the Republican ticket, defeating the Democratic nominee, Mr. John A. Bensel, Past-President, Am. Soc. C. E., the present State Engineer. Mr. Williams was born in 1873 and graduated from Colgate University in 1895, and in 1897 from the law department of Syracuse University. He was for a time City Engineer of Oneida, N. Y., and in 1900 became connected with the State Engineer's department of New York, where he was successively promoted until he reached the rank of Resident Engineer of the Barge Canal. He was elected State Engineer in 1908, and served one term of two years. Afterward he was Chief Engineer of the Coleman du Pont Road project in Delaware, and for the past year or two, until recently, he was Chief Engineer of the Portage County Improvement Association in Ravenna, Ohio, where he had charge of the improvement of 900 miles of roads.

OBITUARY

[illegible] L[illegible], [illegible] of the Flatbush Water Co., Brooklyn, N. Y., died Oct. [illegible]

[illegible] C[illegible], [illegible] member of the [illegible] of Canavan [illegible] Co., Contractors, New York City, died Sept. 21. He was [illegible] years old.

[illegible] S[illegible], a civil engineer with the Pennsylvania State Highway Department, committed suicide at his home in [illegible], Penn., Oct. [illegible]

[illegible], a member of the engineering staff of the [illegible] Co., Pittsburgh, Penn., died at his home in that city Oct. 26, aged [illegible] years. He graduated from [illegible] in [illegible]

[illegible] de [illegible] de Sahla, a director of the old Panama R.R. Co. and associated with Ferdinand de Lesseps in the attempt to build the Panama Canal during the eighties, died Oct. 2[illegible], at his home in Fishkill, N. Y.

[illegible] Ives, former President of the Northern Pacific Ry., died Oct. 2[illegible] at his summer home in Ossining, N. Y. He was born at Farmington, Conn., in 1840 and graduated from Yale University in 1861. He served in the Union Army during the Civil War. He was President of the Northern Pacific Ry. from 18[illegible] to 1896, but was chiefly noted as a financier.

Edward F. W[illegible], former President of the St. Louis & San Francisco R.R., died Oct. 22 at his home in Canandaigua, N. Y. He was born in Maine in 1837. During the Civil War he served as an officer in the Union Army. Following the war he engaged in business as a railway contractor and as such built the St. Louis, Vandalia & Terre Haute R.R., now a part of the Vandalia R.R. He was President of the St. Louis & Southeastern R.R. during the construction period and was also a contractor for the construction of other lines in the Middle West. He was Receiver, Vice-President and General Manager of the Burlington, Cedar Rapids & Northern R.R. and subsequently Vice-President of the Atlantic & Pacific R.R., now a part of the Santa Fé System. Later he was Vice-President of the Manhattan Elevated Rys. in New York City. He was elected President of the St. Louis & San Francisco R.R. in 18[illegible] and the following year was also made President of the New York, Ontario & Western R.R. In addition he was President of the North River Construction Co., chief contractor for the construction of the New York, West Shore & Buffalo R.R.

ENGINEERING SOCIETIES

COMING MEETINGS

AMERICAN ROAD CONGRESS.
Nov. 9-1[illegible]. [illegible] headquarters American Highway Association, [illegible] Building, Washington, D. C.

[illegible] WELFARE AND EFFICIENCY CONFERENCE.
Nov. [illegible]. [illegible] Harrisburg, Penn. Secy., [illegible] Harrisburg, Penn.

NATIONAL MUNICIPAL LEAGUE.
[illegible]. Annual meeting at Baltimore, Md. Secy., [illegible] North American Building, Philadelphia, Penn.

OHIO SOCIETY OF MECHANICAL, ELECTRICAL AND STEAM ENGINEERS.
[illegible]. Annual meeting at Columbus, Ohio. Secy., [illegible] Ohio State University, Columbus, Ohio.

AMERICAN SOCIETY OF REFRIGERATING ENGINEERS.
[illegible]. Annual meeting at New York. Secy., [illegible] New York City.

AMERICAN PUBLIC HEALTH ASSOCIATION.
[illegible]. Annual meeting at Jacksonville, Fla. Secy., [illegible] Massachusetts Institute of Technology, Boston, Mass.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.
Dec. 1-[illegible]. Annual meeting at New York City. Secy., Calvin W. Rice, 29 W. 39th St., New York City.

AMERICAN INSTITUTE OF ARCHITECTS.
[illegible]. Convention at Washington, D. C. [illegible] Washington, D. C.

ASSOCIATION OF AMERICAN PORTLAND CEMENT MANUFACTURERS.

AMERICAN [illegible] ASSOCIATION.
Dec. [illegible]. Annual meeting at Phoenix, Ariz. Secy., J. F. [illegible]

NATIONAL SOCIETY FOR THE PROMOTION OF INDUSTRIAL EDUCATION.
Dec. [illegible] at Richmond, Va. Secy., C. A. [illegible], 140 W. 42nd St., New York City.

SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS.
Dec. 10-11. Annual meeting at New York City. Secy., D. H. Cox, 29 W. 39th St., New York City.

AMERICAN ROAD BUILDERS' ASSOCIATION.
Dec. 14-18. Convention at Chicago, Ill. Secy., E. L. Powers, 150 Nassau St., New York City.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.
Dec. [illegible]-30. Annual meeting at Madison, Wis. Secy., F. M. White, Madison, Wis.

Society of Naval Architects and Marine Engineers—The annual meeting will be held Dec. 10 and 11 at the Engineering Societies Building, New York City. The program includes 1[illegible] papers by prominent engineers.

Association of American Portland Cement Manufacturers—The annual meeting will be held Dec. 7-10, at the Hotel Biltmore, New York City. The Secretary is Percy H. Wilson, Bellevue Court Building, Philadelphia, Penn.

Snow Removal Conference—The Snow Removal Conference, first held in Philadelphia, Penn., last April, is to have another session Dec. 3, at the annual meeting of the American Society of Mechanical Engineers. The reports of the first conference will be read and discussed and much new matter will be presented.

Cleveland Chapter of the American Society of Civil Engineers—The organization of this Chapter was completed on Oct. 28. A nominating committee was appointed to choose and submit to members of the American Society of Civil Engineers in northern Ohio two names each for president, vice-president and secretary-treasurer.

City Planning Convention Held in California—A convention, held under the auspices of the League of California Municipalities, took place at Santa Cruz, Calif., from Oct. 12 to 1[illegible], 1914. Its object was to discuss city planning and to develop a plan which would be applicable to city extension and new towns in that state.

American Institute of Chemical Engineers—The seventh annual meeting will be held in Philadelphia, Penn., Dec. 2-[illegible]. The program includes excursions to a number of large chemical manufacturing plants in and around the city. There will be a number of papers and addresses on "The Present Opportunities for American Chemical Industries."

Portland, Ore., Association of Members of the American Society of Civil Engineers—The association held its annual meeting Oct. 22, when the following officers were elected: President, George C. Mason, Consulting Engineer, and Second Vice-President, John T. Whistler, Engineer, U. S. Reclamation Service. The terms of the First Vice-President and Treasurer do not expire for another year.

American Society of Heating and Ventilating Engineers—The annual meeting will be held in the Engineering Societies Building, New York City, Jan. 19-21. The following officers have been nominated: For President, Dwight D. Kimball, New York; for First Vice-President, Henry M. Hart, Chicago; for Second Vice-President, Frank T. Chapman, New York; for Treasurer, Homer Addams, New York. The Secretary is J. J. Blackmore, 29 W. 39th St., New York City.

American Road Congress—The prospects are that this congress will be a notable one [illegible]. Special trains will leave New York City and other points in the East and Middle West. The convention lasts from Nov. 9 to 14. The program includes many social events as well as technical discussions. There will be a reception at the state capitol [illegible] as the opening [illegible], a tea for the ladies the second day, an [illegible] the evening of the third day, and probably other events to be announced later.

American Railway, Bridge and Building Association—The [illegible] annual convention of this association was held in Los Angeles, Calif., Oct. [illegible]-13. The sessions were presided over by the president of the society, J. N. Penwell.

Committee reports were presented upon [illegible] Bridge [illegible], [illegible] Concrete Bridge Work, Care of Traffic while Constructing Bridges to Eliminate Grade Crossings, [illegible] and Concrete [illegible]. About [illegible] members were in attendance at the meeting, and [illegible] new members were admitted. The officers elected were as follows: president, L. D. Hadwen, C. M. & St. P.; Vice-Presidents, [illegible], N. Y. N. H. & H.; [illegible] W. [illegible]; and [illegible]; Secretary, C. A. Lichty, C. & N. W.; Treasurer, F. E. Weise, C. M. & St. P.; Executive Committee, W. F. [illegible], N. Y. C. & [illegible]; [illegible], C. & N. W.; W. F. [illegible], B. & O.; C. R. Knowles, I. C. RR.; and A. Ridgway, D. & R. G. [illegible] were taken during the meeting to Redondo Beach and [illegible] Park and to Mount Lowe. The next annual convention will be held at Detroit.

959

Engineering News

VOLUME 72 NOVEMBER 12, 1914 NUMBER 20

A Government Power Dam for Municipal Use

Under quite exceptional circumstances, the United States Government is building a dam in the Mississippi River between St. Paul and Minneapolis, to impound water for 12,000- to 15,000-hp. development, and will probably lease the power site to the two cities and the University of Minnesota.* This is the first case, we believe, where such a relation between the government and local communities has been brought about.

FIG. 1. POWER-HOUSE SUBSTRUCTURE OF ST. PAUL-MINNEAPOLIS DAM

(Upstream side. Photographed Jan. 27, 1914, before coffer-dam was removed. Exciter bay at left. Three main wheel bays are shown, each having four stop-log openings. Fall-increaser openings below. At extreme right, dam buttresses and sluiceway gate seats.)

The government is building the dam for both navigation and power purposes. At one end of the dam is built a lock, at the other end a power-house substructure or set of wheelpits. The user of the power will have to install the machinery and the power house covering it, as well as transmission lines, etc.

Construction by Force Account—Building the lock and dam is carried on as a force-account job by the U. S. Engineer Office at St. Paul. Work on an earlier project on the same site, carried on from 1907 to 1910, was handled in the same way. The work has gone on with perfect smoothness and—so far as indicated by the figures given out up to now—very economically. It is expected that the final record will show low cost figures.

Original Features—The enterprise is full of original features. The dam, a hollow reinforced-concrete structure, has its deck made of premolded reinforced-concrete beams laid on the buttresses and anchored to them. The lock, while of ordinary type in both original (13-ft. lift) and final (30-ft. lift) form, involves the unusual feature of walls raised to more than double their original height, and thickened to correspond. The lower gate of the lock is of the vertical-framed type, a type rarely used; it miters at the top only, while at the bottom it bears against the sill and exerts no thrust at the miter joint. The power-house substructure is designed so as to take either vertical or horizontal turbines, with generator room either on top or alongside the downstream wall of the foundation. This latter arrangement was resorted to because the government wanted to leave the user free in his choice of type of machinery. The construction also includes fall-increasers for the turbine draft-tubes, and débris sluices and log sluices.

*This matter is now before Congress, in the shape of a bill which would authorize such lease.

Various phases of the actual construction work are equally [illegible] with the above structural elements.

The present article describes this novel power project as a whole, leaving its separate elements and construction details to be described on other occasions.

Original Project for Two Low Dams

The original 2-ft. low-water depth in the Minneapolis end of the 14 miles of river lying between the twin cities at no time was able to carry commercial vessels. Twenty years ago, a project for canalizing the river in this section was worked out by the government engineers, and Congress approved this project in 1894. Two timber-crib

FIG. 2. LOCATION MAP OF ST. PAUL-MINNEAPOLIS DAM

dams were to be built—No. 1 at Minnehaha Creek, 6 mi. above the Omaha railway bridge in St. Paul, or about 3½ mi. above the mouth of the Minnesota River; and No. 2 at a point 2 mi. farther up, or about 3 mi. below St. Anthony Falls in Minneapolis. Each dam was to have a lock [illegible] ft., with a lift of about 13 ft. and a miter-sill depth of 5 ft. The upper pool would be about 6 ft. deep nearly to the falls.

Various causes delayed the start of the work until [illegible]. In that year construction of Dam No. 2, the upper dam (see sketch map, Fig. 2), was begun, as this dam by itself would support navigation between St. Paul and Minneapolis at least [illegible] months in the year, while the lower dam by itself would give only one month's navigation. The concrete lock-chamber and the timber dam at No. 2 [illegible] under the disadvantage of interrupted appropriations, and thus were not completed until the end of [illegible].

In [illegible] the construction of Dam No. 1, the lower dam, was started, and by [illegible] it was completed.

The Power Project

[illegible] conditions. The people of the region looked toward the power possibilities of the dams; the same water would pass them that has for years been supplying water to the Minneapolis mills at St. Anthony Falls. But study of the power question showed that the two combined dams would not be economical sources of power as compared with a single dam of the combined head. Upon working out the single-dam project, the conclusion was reached that the old project should be abandoned and the new project adopted. Congress authorized the change in the 1910 River and Harbor Act. The lower dam is being built to a height of 30 ft., and Dam. No. 2 will be submerged, a few feet of its top having been blasted off to give the required channel depth.

The navigation side of the project was modified somewhat in the same revision. A 6-ft. depth was adopted in place of the old 5-ft. depth, and the lock is expected to give 7 ft.; river works below have been planned to give 6 ft. Some account, even, has been taken of a possibility that 9½-ft. navigation may be wanted in the remote future. The dam is higher than the combined height of the original project, and the upper reach and upper entrance of the lock will give the 9½-ft. depth. But the river below the dam would need to be raised for a 9½-ft. depth at the lower entrance, by wing dams or equivalent work.

As designed and as being built, the dam will have a crest elevation of 743.5 Cairo datum (722.24 ft., sea-level datum), and the tailwater an elevation of 712, giving a head of 31.5 ft. Provision is made for using 3 ft. of flashboards, and the river work below will probably lower the tailwater about a foot. Thus the low-water head will be 32.5 without flashboards and 35.5 with flashboards. At high water, the head may be reduced to about 26 ft. Normal floods are expected to flow 4 to 5 ft. over the crest. The upper lock gate and the lock walls are built for extreme floods (never recorded, but believed to be remote possibilities) of 9 to 10 ft. over the crest.

The dam crest is 575 ft. long; out of a river width of about 900 ft. the lock takes up about 100 ft. and the power house about 200 ft.

This power development has an intimate relation to the famous Mississippi headwaters reservoir system. Beginning in the early '80's, a series of six large storage reservoirs was built about 400 miles above Minneapolis, partly by raising the levels of existing lakes and partly by damming river valleys. Their purpose is to increase navigable depths on the Mississippi above Lake Pepin, while the navigation actually existing in this stretch of river is very small, the effect secured in increased depth is considerable.

The normal drainage of the region aided in midsummer by the reservoir discharge, keeps the flow at St. Paul well above a minimum of 5000 to 6000 cu. ft. per sec. throughout the spring and summer months and on into late autumn. Beginning about November, a natural low-water stage and the closure of the reservoirs brings the flow between November and the middle of March to a point below 3000 and sometimes down to 1500 cu. ft. per sec. The high-water flow (June) rarely goes up to 40,000 cu. ft. per sec.; [illegible] is taken as a remote possibility.

The flow at St. Paul is augmented by the Minnesota River. At the dam it is figured at 4000 sec.-ft. summer flow for power.

Under these conditions, the power of the river at 35 ft. head can be taken at about 12,000-15,000 hp. utilizable for nine months of the year. The winter power, however, may at times drop as low as [illegible] hp. The consumption of current for lighting, pumping and street-railway [illegible]

by the two municipalities and by the State and Federal authorities in the local territory amounts to about 3000 kw. (4000 hp.).

The power-house substructure at the dam has been designed for four 3800-hp. units. If this capacity is installed and full demand develops, auxiliary power must be generated or bought, to bring up the deficit during the period from November to March. It is probable that a steam power station would be built as a supplementary source as soon as the demand grows beyond the winter power.

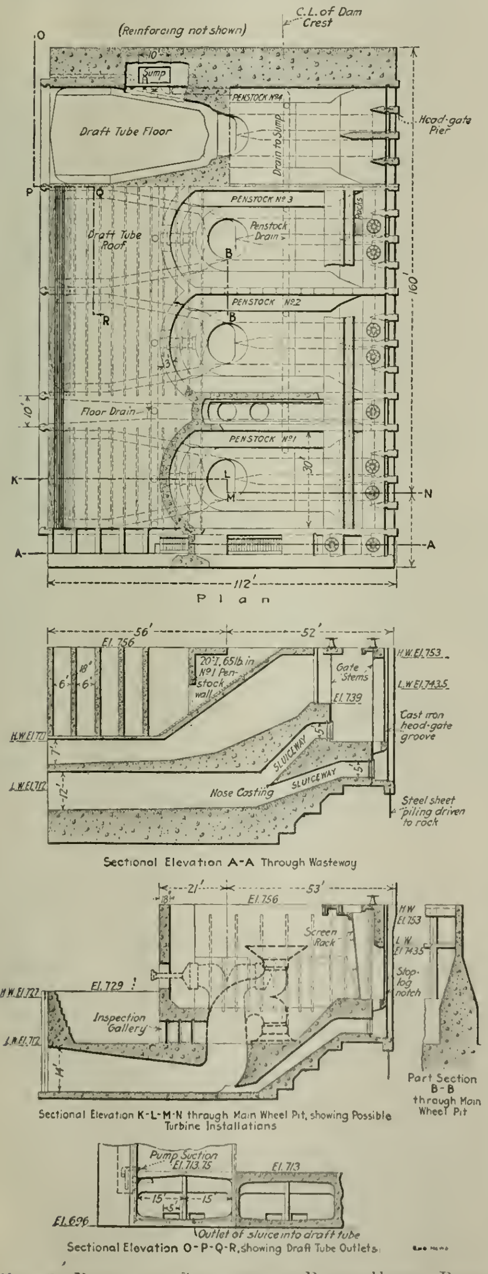

Fig. 3. Plan and Sections of Power-House Base, St. Paul-Minneapolis Dam

The power-house layout is sketched by the two sections and the plan in Fig. 3. At the land end of the four cells or chambers is a narrow bay divided into three sluiceways, one above the other, the lowest two, merging into a common outlet, being the débris chutes, while the upper one is a log chute. Between the first and second power bays from the land end is a narrow exciter bay. The power bays are simple vertical cells divided by a floor some distance above the downstream pool level, which separates the headbay from the tailbay or draft-tube section. The draft tube is a curved tapering passageway changing from circular to rectangular section, and at the same time bending from vertical to horizontal direction. At its lower bend an opening from the upstream side enters; this serves partly as sluiceway and partly as fall increaser (Herschel style). The exciter draft tube has no such fall increaser. The position of screen racks, gates, and stop-log notches is apparent from the drawing.

The water-wheel chambers are intended to be large enough to accommodate either vertical or horizontal wheels. In the case of vertical wheels an intermediate machinery floor would have to be built, and over it a house inclosing and covering the waterwheel cells. In the case of horizontal wheels the power house would be downstream of the lower forebay wall, on a ledge provided for the purpose above the draft tube.

The principal change made from the original designs of Gardner S. Williams, of Ann Arbor, for the hydraulic layout was shifting the exciter bay one panel toward the land—it was originally located between the second and third cells—and making the downstream walls of the forebay in the shape of three chords to the original circular arch.

This concrete substructure is fully reinforced in all directions. The vertical partitions between the wheel cells were designed and reinforced as cantilevers to resist the pressure when one cell is full and the adjoining one empty. In a similar way the downstream walls of the wheel cells are designed as cantilevers from the dividing walls; at the middle of each of the downstream segmental walls there is an expansion joint, to localize any possible formation of cracks.

The foundation work at this locality was somewhat troublesome, inasmuch as the St. Peter sandstone rock which forms the almost vertical bluff of the river gorge dips down below foundation level at about one-third the length of the power house out from the land end. The result is that part of the power house rests on rock and part rests on piles—1200 piles, 10 to 20 ft. in length. The subsoil here is a sand and gravel river deposit which is believed to be very hard and firm. No differential settlement of the two parts of the foundation is anticipated.

The lock and dam were designed by the U. S. Engineer office of the St. Paul District. Up to August of 1912, Lieut.-Col. F. R. Shunk was in charge of the district, and since that period Lieut.-Col. Charles L. Potter has been in charge. During both administrations the work was under the superintendency of Assistant Engineer Geo. W. Freeman, who has also been in charge on the ground as works superintendent.

Operation of Sand and Gravel Plants

By W. H. Wilms*

SYNOPSIS—This is a continuation of the article on "Development of Sand and Gravel Deposits," by Mr. Wilms, in Engineering News *of Nov. [illegible], 1914, p. [illegible]. The present article discusses the necessary equipment for a screening, washing and crushing plant, method of operation, the necessary facilities for a successful plant, with some recommendations based on several years' operating experience.*

Screening and Washing

Screening—The conical revolving screen, better known as the Gilbert screen (patent rights run out) has now practically supplanted all other types of screens in the screening and washing of sand and gravel. The screen is cantilevered, being supported at one end only, except in the very large sizes when the screen shaft extends through the screen with a bearing at each end. The small end of the screen is closed by a solid casting, in which the screen shaft is fastened. In the operation of the screen the material is carried to the small end of the screen in a chute (Fig. 1), which runs into the screen and discharges almost against the head at the small end.

The material, [illegible] must reverse its direction to work out of the screen and in so doing practically all of the original velocity gained in the feeding chute is lost at this point, and the gravel passes slowly and evenly through the screen, due to its [illegible] and inclined [illegible]. Thus the entire screen surface becomes effective and large capacity and uniform sizing result.

The screens are generally arranged in a series as shown in Fig. 1. The oversize from the first screen drops into the [illegible] and the material which passes through the perforations is carried by water through a [illegible] into the [illegible] end of the second screen. This process is repeated [illegible] each size of [illegible] separated.

The first screen has usually 1½-in. or 1¼-in. perforations, and all material over 1½ (or 1¼ in.) is discharged into a chute leading to the crushers for reduction.

Washing—The washing process now begins, the revolving motion of the screens breaking the soil and foreign matter away from the gravel. The next size of gravel is separated from the mass by the second screen in the same manner as the first. The second screen usually has ¾- or ⅝-in. perforations, and the material in the second bin is everything between 1½- or 1¼-in. and ¾- or ⅝-in.

The remaining screens are sand screens with perforations dependent upon the size and grade of the sand desired. After the material passes through all the screens the sand and muddy water remain, the sand being taken from the water by a settling tank.

To assist in the washing process and to prevent the material from discharging too rapidly and carrying over some of the finer parts, fresh water is injected into each screen. This fresh water is a rinsing water also, and prevents the material passing through the screen from piling up in the spouts directly beneath.

This in brief is a description of the screening and

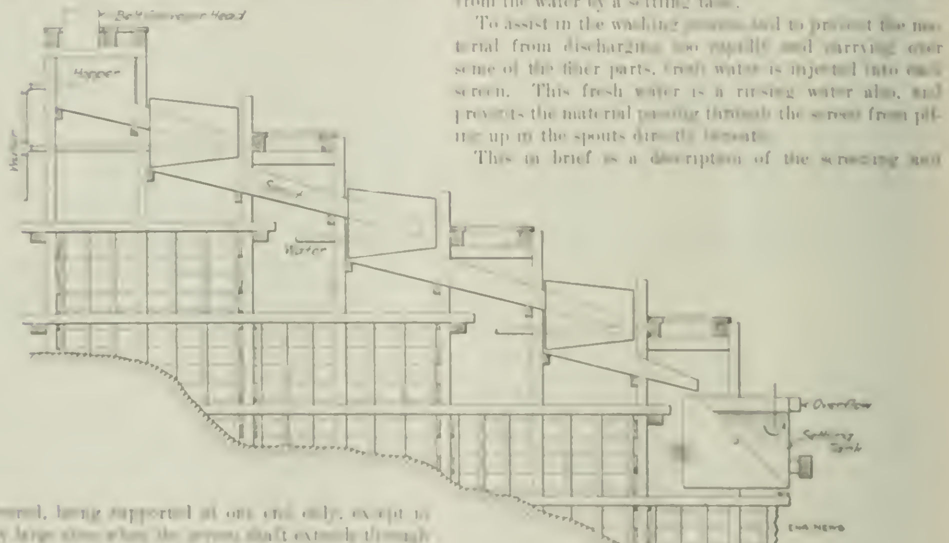

Fig. 1. Ordinary Arrangement of Gilbert Screens

washing process in use at the present time. The arrangement of screens and other details, of course, vary with the conditions and the ideas of the operator, but the process is essentially the same in all plants using the Gilbert screen.

Feed Hopper—By whatever means the material is elevated to the screening bay, it is quite essential that it should first be delivered into a large and ample bin or hopper before being fed into the initial screen, for it is here that the material receives the greater part of its [illegible]. The chute carrying the material from this bin to the initial screen should have as low a pitch as possible; otherwise the water will quickly escape and its [illegible] and [illegible] action will be rendered nil.

Ordinarily at least [illegible]% of the entire amount of water used should be delivered into this [illegible] hopper. I recently visited a large plant where this hopper was nothing more than an extension of the chute leading into

*[illegible] Engineer [illegible]

the initial screen. This chute was on about a 45% slope with the result that the water injected into the material flowing in the chute had no washing action whatever. The material has been so imperfectly washed as a result of this feature that the superintendent of the plant has decided to tear down the present arrangement and rebuild.

Wash Water—There are several methods employed in applying water to the material in the screen, depending upon the amount of dirt and impurities in the gravel and the size of the screen perforations. Fig. 2 shows the ordinary method when the dirt, clay or other impurities are in the free state and easily washed out.

When the material contains considerable foreign matter, or the gravel is coated with a hard film of clay, it is often necessary to supplement the spray pipe, shown in Fig. 2,

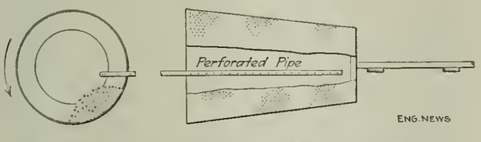

Fig. 2. Ordinary Method of Applying Water to Screens

with an injection of water under pressure in the manner shown in Fig. 3. The pressure of this stream tends to keep the material in the screen for a longer period, resulting in a more thorough washing. In the screening of some sands that have a tendency to clog the screens, it is often necessary to keep a spray of water playing on the outside screening surface to prevent this (Fig. 3).

Amount of Water—The amount of water necessary for the thorough washing and cleansing of the material depends upon the amount of impurities contained in it, the nature of the impurity, whether loam or clay, and whether or not this loam or clay is finely divided and

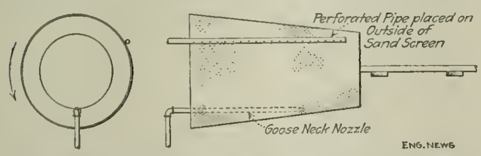

Fig. 3. Method of Applying Additional Wash Water

in a free state or covers the material in the form of a hard film.

The amount of water necessary also depends upon the percentage of sand contained in the gravel being screened and upon the nature of the sand, whether light or heavy, fine or coarse. As a minimum for reasonably clean bank or stream deposits, 1 gal. per min. per cu.yd. of material should prove effective, although if the percentage of sand runs high, this figure will probably have to be increased. Too much water can hardly be used—the more water the more effective the screening. Extremely dirty material will often require double the above amount, and even then the results are not likely to prove entirely satisfactory.

The necessity of an adequate and reliable water supply cannot be too strongly emphasized. I know of an instance where an efficient and otherwise promising plant proved an utter failure due to the impossibility of obtaining a sufficient water supply for effective washing and screening. This feature is of equal importance with the quality of the bank gravel itself, and the determination as to whether there is a sufficient and reliable water supply available should be one of the first considerations in a new development.

Re-using Water—A number of plants that are suffering from a lack of sufficient water—and there are many—have improved the quality of their product considerably by using part of the water over again. The waste water from the settling tank is permitted to flow into a storage tank provided with an overflow, located either upon the top of the storage bins or upon the ground. A centrifugal

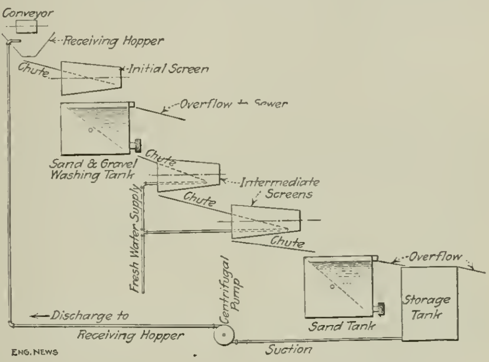

Fig. 4. Washing Arrangement with Automatic Settling Tanks

pump is used to pump this waste water from the storage tank back to the gravel hopper at the head of the screens. No fresh water is used in the gravel hopper, the preliminary washing here being effected with this return waste water.

While this method will undoubtedly improve the quality of the material where the water supply is insufficient, it can be improved upon considerably by providing an arrangement whereby this return waste water after effecting the preliminary washing in the receiving or gravel hopper is not permitted to enter the screens, but is allowed to run to waste. The present methods of washing sand and gravel without exception are all open to the objection of permitting the dirty water from the receiving hopper to travel with the material through the entire battery of screens to the settling tanks. When it is considered that the greater part of the washing is effected in the receiving hopper, the reason why some plants handling dirty material are not producing a clean product becomes apparent.

It is my contention that with dirty material, and most bank gravel contains far more dirt and foreign matter than is generally realized, the water used in the preliminary washing should be taken from the overflow of the settling tanks and should not be permitted to enter the sizing screens at all.

With the same amount of water, a plant washing its material in this manner would undoubtedly produce a cleaner and better material than with present methods. To effect such an arrangement for washing, it would only be necessary to first deliver the material directly from the receiving hopper to the initial screen to take out the oversize and then deliver it to a settling tank, similar in design and operation to a sand-settling tank, for taking off this dirty water. The initial screening is necessary so

go to remove the coarse material which would otherwise clog up the discharge openings of the tank.

Automatic Settling Tanks—Extensive test runs with automatic settling tanks handling 1½-in. material and sand show that such tanks when properly designed with large discharge openings will operate satisfactorily when used for this purpose. It should be understood, however, that complete washing of the material in such a tank is not to be expected, as a considerable quantity of the dirty water must of necessity pass out of the tank with the material to cause it to flow and discharge itself. More than half of the dirt and impurities, however, can ordinarily be removed by the tank. Fig. 4 is a sketch of the washing arrangement above outlined.

Screens

Both round and slotted perforations are used in sand screens, depending upon the shape and size of the sand grains. A great many river sands and some bank sands contain a considerable percentage of long, angular-shaped grains, while the grains of common bank sand are usually round.

Attention should be called to the necessity of providing at least one intermediate screen between the initial and sand screens. Any attempt to screen out all of the sand by means of only two screens will almost surely result in failure. Where all of the material passing through the initial screen is taken direct to the sand screen, as is only too often the case, the sand screen becomes overcrowded and unable to effectively perform its screening, resulting in a large percentage of the sand and dirty water going over the screen with the gravel.

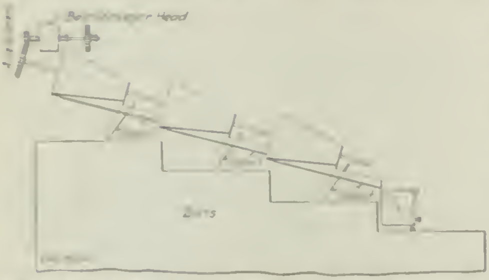

Fig. 5. Battery of Screens of a New Type Made by the Raymond W. Dull Co., Chicago, Ill.

I have seen instances where this crowding of the sand screen was deliberately done to get rid of some of the sand, of which there was an excess in the bank and which could not otherwise be disposed of. It is done, however, only at a sacrifice of the quality of the material produced. To prevent crowding and to permit of effective screening, an intermediate screen should be used even though there may be no demand for the size of the material the screen produces.

Perforations—In screening some sands it is often necessary to use a round perforation, as these long, angular particles of sand would effectively clog up the perforations of a slotted screen, whereas a round hole will reject them. I have also had experience with a sand that, when screened through a screen having round perforations, would so effectively clog them up as to require the use of a screen-guard and hammer to clear the holes. With a slotted screen, however, I had no trouble in getting this sand through without clogging.

In the manufacture of sand screens, that side of the screen plate upon which the punching of the perforations was performed should be made the inside or wearing surface of the screen. Punched holes in steel plate are slightly larger upon one side than upon the other, and in order that the perforations may freely pass through any particle when once started, it is necessary that the small diameter of the hole be on the inside. This feature, though a small one, has caused many operators much trouble and expense. While many screen manufacturers are aware and take care of this detail, many do not; therefore it should always be mentioned when ordering sand screens.

Speed—The speed of conical screens that has been found most effective is from 12 to 14 r.p.m. for the ordinary size of screen, and 9 to 11 r.p.m. for the extremely large sizes. Faster speeds than this cause the material to climb up on the side of the screen with a consequent loss in screening capacity. From test runs it has been found that the most effective speed is that at which the material in the screen makes an angle of about 30° with the vertical.

Pitch—The screening surface of a Gilbert conical screen has a pitch of 1½ in. to the foot for all sizes. While many screens having different ratios of length to diameter at the small end are in use, the following sizes have more or less been standardized, having been found the most effective under average conditions (dimensions are given in the order of small diameter, large diameter and length):

24x30x54 in.	36x54x72 in.
28x44x60 in.	42x61x84 in.
	48x72x96 in.

Size—The size of screen necessary for a given capacity depends upon so many factors, such as size of perforation, uniformity of feed to the screen, amount of impurities in the material, amount of water, etc., that no table of capacities can be given that would be of any value.

The size most used, however, is the 36x54x72, the required capacity being obtained by using a number of these screens in parallel. In order to reduce the number of spare parts necessary to be kept in stock for emergency use and to permit of the interchangeability of the screen plates of the various screens, it is generally advisable to have all of the screens with the exception of the initial screen of the same size.

Wear—The wear on screen plates is very severe and rapid, the perforated holes become enlarged, resulting in imperfect grading. As heavy a screen plate as practicable should be used. It should be remembered, however, that as the thickness of the screen plate increases, a larger diameter of hole becomes necessary for the screening of a given-size material. The following sizes of plates for the different sizes of perforations have been found by experience to be very economical and effective under ordinary conditions:

[illegible]
[illegible]
[illegible]
[illegible]
[illegible]

Size of Perforations—To make a given-size product, a larger diameter of round perforation must be used owing to the angle and thickness of the screen plate at the point where the stone passes through. The follow-

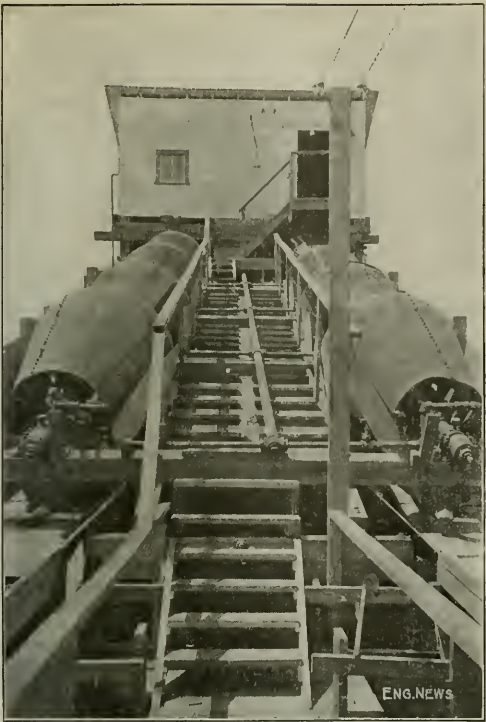

Fig. 6. Battery of Screens; Chicago Sand & Gravel Co.

ing table gives the relative sizes of material and screen perforations:

Size of material	Screen perforation
¼-in.	$\frac{5}{16}$- to ⅜-in.
⅜-in.	½-in.
¾-in.	⅞-in.
1-in.	1¼-in.
1½-in.	1¾-in.
1¾-in.	2¼-in.
2- in.	2½-in.
2½-in.	3- in.

Chutes—The grade of the chutes or spouts into the screens, and of the outer skirts carrying the material passing through the screens, varies from 3 to 4 in. to the foot, depending upon the size of the material and the amount of water being carried.

The tendency here is to use too great a grade for the chutes between the various screens, resulting in an excessive height to which the material must be elevated. I know of a case where in the reconstruction of a certain large plant something like 8 ft. in elevation was saved by reducing the excessive chute grades between the screens. It is not unusual to see plants with chutes having grades as high as 8 in. to 1 ft.

The chutes between the gravel screens very rarely require a fall of more than 3 in. to 1 ft., while the chutes between the sand screens and settling tank can generally be operated on as low a grade as 1½ in. to 1 ft.

In the handling of very dirty gravel it is especially important that the grades of the chutes be no more than what is actually required, for in such cases it is necessary to introduce jets of water in the chutes to effectively wash the material. If the grades of the chutes be excessive the gravel will travel or flow about as fast as the water, consequently the scrubbing action of the water which would obtain on a flatter slope, would here be ineffective.

Double Screens—Where the screening out of the oversize material is performed on top of the plant at the head of the battery of sizing screens, it has sometimes been found advisable to perform this initial screening in the first sizing screen by means of an inner screen plate extending about 6 in. beyond the discharge end of the outer screen plate.

While this method eliminates an extra screen with the consequent saving in head room, a larger screen than is ordinarily required must be used to compensate for the decreased capacity of the outer screen plate.

This screen plate receives its material its entire length and not at the head end as is usually the case. Consequently, material passing through the inner screen plate and upon the outer plate at the end of the screen receives very little if any screening. For this reason, the screen must be made amply large where the two are combined in the above manner.

It is sometimes found advisable to provide a screen with an inner skirt or screen plate with perforations about ¼ in. larger than those of the outer plate, the skirt extending nearly the full length of the main screen plate. This is for the purpose of increasing the screen's capacity by relieving it of the larger sizes and for making the separations more accurate.

Deflector Vanes—Where the material is extremely dirty, short pieces of angle iron bolted to the initial washing screen, and arranged spirally on the inside of the screen plate, have often proved effective by retaining the material in the screen for a longer period, resulting in a more thorough washing.

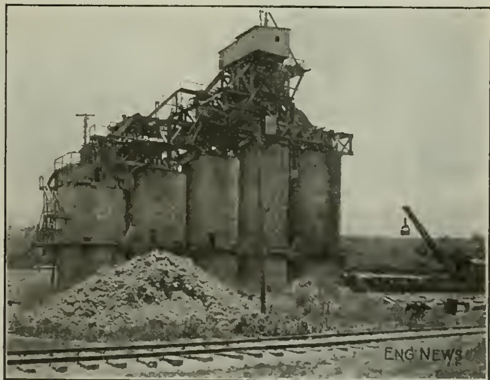

Fig. 7. Storage Bins; Chicago Sand & Gravel Co.

Inclined Gravity Screens—In the operation of a plant, it is often necessary to use short sections of inclined gravity screens; such screens, however, should be used sparingly, for even under the best of conditions such screens produce a material that is very imperfectly graded. The material in sliding over the screen plate acquires a velocity in a very short time that prevents the material from going through the perforations. For this reason only the first 4 or 5 ft. of the screen are really effective.

Inclined screens of the bar type have the further objection of permitting a large percentage of over-size material to pass through the bar openings. Neither can a thorough washing and cleansing of the material be effected on this type of screen. I have yet to see anything like a well graded and washed material produced over gravity screens.

A New Type of Screen.—Mention should be made here of a washing screen that has been in service in a large number of plants throughout the country during the past two years. This screen is giving such satisfactory results that it is worthy of a brief description. One of the largest plants in this country with a daily capacity of [illegible] cu.yd. is now installing a battery of 24 of these screens.

This type of screen is in many respects an improvement over the Gilbert screen. Referring to Fig. 5, the screens of a single battery are all mounted on the same shaft. A single pair of gears is used to drive all the screens, thus dispensing with a separate drive for each screen, with the attendant line shafting, bearings, gears, sprockets and chains. The material also travels differently in this style of screen, being delivered into the large end and traveling toward the small end as shown in Fig. 4.

The feature that appeals to the writer in this type of screen, however, is that the large end of the screen does the principal work. The large end has more perforations, more screening surface and consequently a greater capacity than the Gilbert screen. Greater screening efficiency, less power and small upkeep expense are claimed for this type of screen.

The screen has longitudinal joints and can be dismantled from the shaft without disturbing the shaft. Pipe nozzles are placed at the discharge end of the screens for injecting water to prevent the material from discharging too rapidly and carrying over some of the finer parts. This screen is patented and manufactured by the Raymond W. Dull Co., of Chicago, Ill.

[This article will be concluded in a forthcoming issue.—Ed.]

Rapid Construction of a Large Reinforced-Concrete Warehouse

The Austin-Nichols warehouse, which has just been completed at North Third St. and Kent Ave., in Brooklyn, N. Y., is a good example of a modern reinforced-concrete building of the warehouse type, and the remarkable progress made in its construction is indicative of what can be done in reinforced concrete with proper organization and supervision.

The building is located on the East River waterfront, immediately alongside of one of the railway terminals, tracks from which enter the second story of the

Figs. 1 to 6. Progress Views of Construction of Austin-Nichols Company Warehouse, East River Waterfront, Brooklyn, N. Y.

[illegible]

warehouse. These tracks are carried on steel girders and columns, but the entire remainder of the building is of reinforced concrete, the structure being of the regular column, girder and slab type. The building is 440 ft. long and 178 ft. 8 in. wide, and has six stories and basement, the story height being 12 ft. 6 in. from floor to floor. It is to be used as a storage warehouse for the large grocery firm, Austin Nichols & Co. Each typical floor bay is 16 ft. 6½ in. by 19 ft. 5 in. and is carried on 2-ft. x 7-in. beams framing into 2-ft. 5-in. x 12-in. girders, which frame into the columns. It was erected on soft foundations, which required timber piles and reinforced-concrete grillages carrying the column footings. It contains 23,000 cu.yd. of reinforced concrete, which required 32,200 bbl. of cement and 1567 tons of reinforcement. There were over a million square feet of lumber in the forms and some 2500 piles used in the foundation, which had 26,400 cu.yd. of excavation. These figures will give some idea of the size of the building.

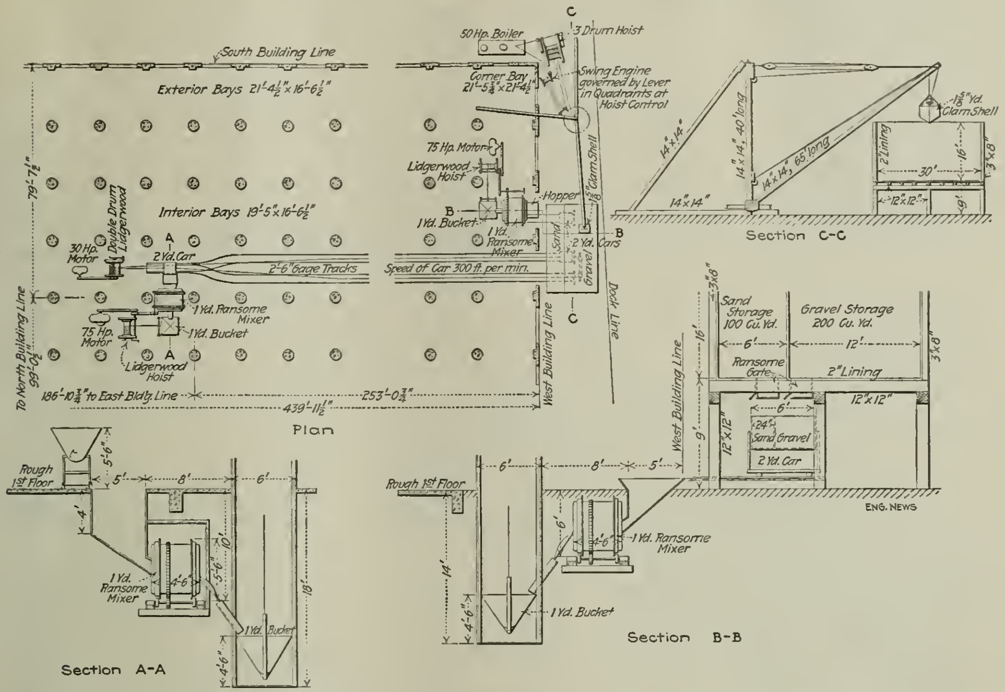

FIG. 7. DETAILS OF CONCRETING PLANT ON AUSTIN-NICHOLS BUILDING

The contract for the building was awarded on Dec. 1, 1913, and called for substantial completion on Sept. 1, 1914. Work was started on the foundations very soon after the awarding of the contract, but concreting was not commenced until March, 1914. From that time on, speed records in concrete construction were made. The mixing plants were installed as shown in the accompanying Fig. 7. One plant was located at the dock line of the building, and here was placed the storage for the concrete material, which was brought in by barges, and loaded directly above the mixer in sand and gravel bins. Alongside of the storage plant was located a mixer and a concrete elevator. Into this mixer the materials were chuted by gravity. The other mixing plant, a duplicate of the first, was located at the other end of the building, and was approached from the storage bin by narrow-gage tracks, on which cars, driven by an endless cable, carried the material to the mixer. All machinery was electrically driven. With these two plants, 695 cu.yd. of concrete were placed in one 8-hr. day.

The progress in carrying up the building is shown in the accompanying views, Figs. 1 to 6, which give approximate monthly progress on the work. As a rule, one entire floor, including columns, beams, girders and floor slabs of 80,000 sq.ft. of floor space, was concreted in five days at the rate of 16,000 sq.ft. of floor per working eight-hour day, with 600 men working on the building. One set of side-wall forms was used and the stated progress permitted the removal of the first placed side forms on any one floor for the beginning of the next floor by the time the first floor had been finished; that is, the side forms were allowed to stay in about five days. The struts supporting the floor system were, of course, allowed to stay in the regulation three weeks.

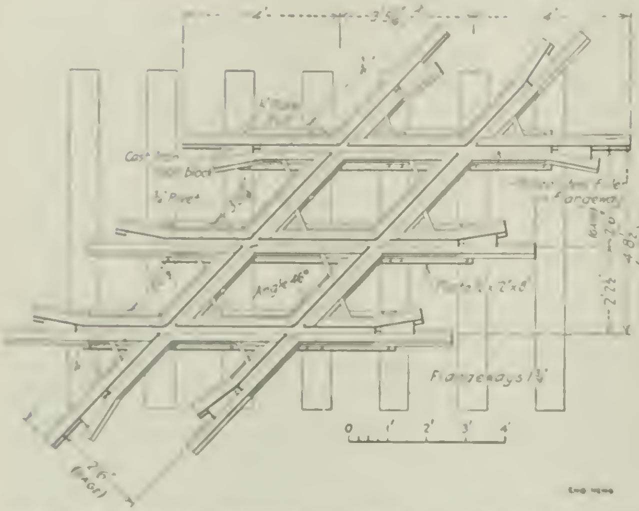
The architectural design of the building, which was made by Cass Gilbert, of New York City, is somewhat unique, as Fig. 6 will show. The grouping of small windows in parallel lines in both directions gives a different appearance to the building than is common in reinforced-concrete buildings. This was permissible, of course, on account of the nature of the building, which did not require any very great amount of natural light.

The entire contract was carried out by the Turner Construction Co., 11 Broadway, New York City, in the contract period of nine months.

Track Crossing for Mixed Gage

In the yards of timber- and tie-treating plants, systems of narrow-gage tracks for the cylinder cars are required to serve the storage yard, treating plant and shipping platforms, and some of these are three-rail or mixed-gage tracks for both the tram cars and standard-gage cars. The crossings of these tracks are somewhat complicated, and we illustrate herewith the crossing of a mixed-gage track and a narrow-gage track in the yard of the new tie-treating plant of the Louisville & Nashville R. R. at Guthrie, Ky.

The crossing is built of 70-lb. rails, with a ½-in. plate, 12 in. wide and 8 ft. long, riveted under each rail of the three-rail track with ¾-in. rivets, thus making a very substantial construction. These plates are punched with



TRACK CROSSING FOR A MIXED-GAGE (4 FT. 8½ IN. AND 2 FT. 6 IN.) AND NARROW-GAGE (2 FT. 6 IN.) TRACKS IN THE YARD OF THE TIE-TREATING PLANT AT GUTHRIE, KY., L. & N. R.R.

¾-in. square holes for the spikes. Fillers of rolled or forged steel extend the full length of the straight portion of the flangeways (which are 1¾ in. wide and 1⅞ in. deep), and 1½-in. knees of the same material are fitted at the intersections. Cast-iron footguards are placed at the flared ends of the guard rails. The rails, fillers, etc., are put together with ⅞-in. bolts, there being seven bolts in each end portion and five between each pair of intersections. J. H. Lindsay is Superintendent of Timber-Treating Plant.

Liquid Chlorine for Water Treatment at Milwaukee, Wis., is being considered as a substitute for the hypochlorite treatment now employed. [illegible]

New Municipal Asphalt Plant, San Francisco, Calif.

By B. E. Dunn*

The city of San Francisco has under construction a new plant for the manufacture of asphaltic-paving mixtures, the cost of which will be approximately $57,000. The plant, property and railroad facilities, represent an investment of about $130,000. The capacity will be 180 batches or 320 cu. yd. of wearing surface, or binder, per day.

AGGREGATES—All material is brought to the plant on cars, no teaming being necessary. The sand, rock or gravel is dumped from the cars into a concrete receiving hopper having a capacity of four carloads or 200 tons, from which it is hoisted to a screen and segregated into the proper bin. The elevator has a capacity of 85 tons per hour. The screen is 18 in. in diameter by 22 ft. long, with adjustable jacket. All lime dust is unloaded from the car into a storage room, whence it can be taken as needed (see plan and elevations, Figs. 1 and 2).

STORAGE BINS—As designed, storage bins for the rock and sand are of reinforced concrete, 12 in number, 12 ft. square and 24 ft. deep and have a combined capacity of 1536 cu. yd. Under the storage bins are two belt conveyors with a capacity of 36 tons per hr., and the material is fed from the bins upon the belt conveyors by special measuring gates (Fig. 3).

SPECIAL MEASURING GATES—These gates can be opened or closed by a shaft gear directly over the belt, which in turn is operated by the belt conveyor. On the shafts are fitted eccentrics, which operate a lever, and by means of a pawl and ratchet the gate is revolved. Each gate has a range of capacity of from 2 to 12 cu. ft. per min., and any mixture of fine or coarse rock or sand can be sent to the dryers.

The material when taken from the belts is hoisted by an elevator and discharged into the uptakes of the dryers. These uptakes are fitted with baffle-plates over which the material slides, coming in contact with and being partially heated by the escaping gases before entering the revolving drying drum.

DRYERS—The drying cylinder is designed with an inclination of 1 in 16. Its shell is ⅝ in. thick, 5 ft. in diameter and 12 ft. long, lined internally with eight 6-in. channels by which the material is carried up and dropped through the flame, gradually working its way toward the lower end of the drum. Each dryer is fitted with a firing hood, on wheels, similar to that used for an ordinary cement cooker.

HOT MATERIAL BINS—Below the firing hood are two flight conveyors each with a capacity of 36 tons per hr., and designed for hot material. The flight conveyors dis-

*Assistant Engineer, Board of Public Works, San Francisco.

charge to elevators of the same capacity, which in turn empty into the small storage bins for hot materials above the mixers.

The lime dust is conveyed from the storage room to the hot bins by a flat belt-conveyor fitted with oak strips. The dust is emptied directly upon the belt through a hopper, and all the free dust arising is drawn through a fan discharging into a centrifugal separator, from which it falls back upon the belt.

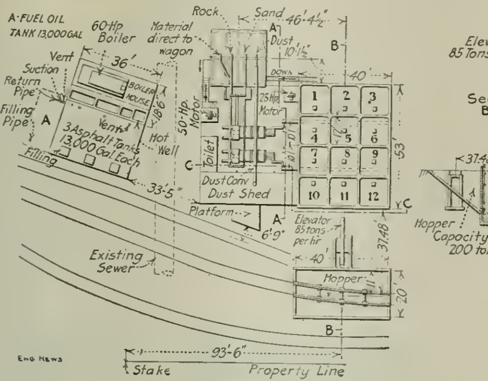


Fig. 1. Plan of the New Municipal Asphalt Plant, San Francisco, Calif.

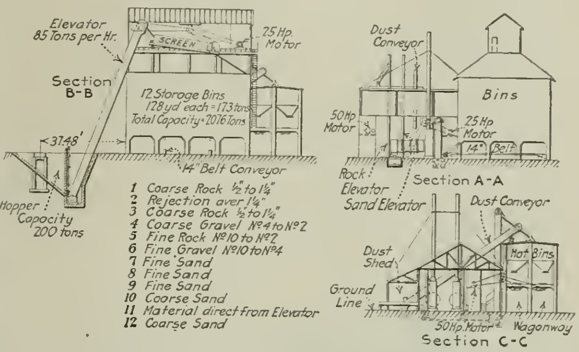

Fig. 2. Sections of New Municipal Asphalt Plant, San Francisco, Calif.

The hot bins and mixing platform are of reinforced concrete and the dryer shed of steel and corrugated iron.

Measuring Hot Aggregates—Under the hot bins are special measuring boxes for sand, rock, dust and asphalt. Those for sand, rock and dust consist of revolving cylinders open on one side. When the opening in any cylinder is opposite the bin material drops in, and when the cylinder revolves again until the opening is underneath, the material drops out into a hopper. The rock and sand cylinders have a capacity of 3 cu.ft. per dump.

Asphalt Measuring Device—Asphalt is fed to the mixers in a liquid state and is measured in horizontal cylinders having an internal piston worked by a screw and hand wheel. By changing the position of the piston the size of the chamber and the amount of asphalt used can be controlled. Each cylinder is steam-jacketed and is fitted with a thermometer so that the attendant can easily read the temperature of the liquid before injecting it into the mixer. Asphalt is forced from the measuring cylinder into the mixer by means of compressed air.

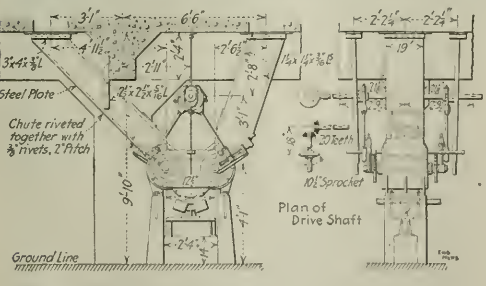

Fig. 3. Measuring Device for Aggregates, San Francisco Municipal Asphalt Plant

Mixing Units—The mixers are 4 ft. 8 in. long x 3 ft. 5 in. wide, with a capacity of 12 cu.ft. per mix. The shafts are 3 in. square and are fitted with 12 sets of semi-steel paddles on each shaft. The shell is ¼-in. steel plate and the heads are of cast iron. While the mixer works on one batch the next batch will be prepared in the hopper directly above. One man can perform all of the operations for each mixer.

Asphalt Heater—A 60-hp. boiler with superheater furnishes steam for heating the asphalt in the tanks, each tank having forty-eight 20-ft. lengths of 1½-in. pipe, with all screwed joints welded. The temperature of the asphalt is controlled by a thermostat operating a valve on the steam line. A steam line also furnishes a means of heating asphalt in the car, which is unloaded by a 2½-in. gear pump, the suction and discharge piping being 3 in. in diameter with an internal ½-in. steam pipe for heating.

An oil-burning system for the boilers is operated with compressed air, which is also used for blowing out the asphalt pipes when closing down. The plant is also equipped with a large centrifugal pump for pumping out any of the elevator pits, should water collect.

All machinery is driven by electric motors, one 50-hp. motor being used to operate the main elevator and screen; one 25-hp. motor to operate the belt conveyors, elevators and dryers; one 25-hp. motor to operate the flight conveyors' elevators and mixers. The air compressor is operated by a 10-hp. slip-ring motor, automatically controlled.

To operate the entire plant, nine men are required: one for the receiving hopper, one in the screen house, one for the dryers, two for the mixers, one for the boiler house, one for the dust shed, one to tend asphalt and dust cars and one superintendent.

The buildings and equipment were designed under the direction of M. M. O'Shaughnessy, City Engineer.

All Paving Records in Galveston, Tex., have been Broken by the city expending more than $200,000 on street pavements during the first nine months of the present year.

A New Rotary Air Compressor

A task which has attracted many inventors is the production of a successful rotary air compressor. For low pressures, such machines are, of course, in very extensive use, the two best known types being the fan blower, suitable for operating against pressures up to a few ounces, and the pressure blower, consisting of two interlocking pistons, which can compress air with fair efficiency up to three or four pounds pressure.

Another type of machine which is becoming more and more common is the high-speed multi-stage compressor, which, while it operates on the same centrifugal principle as the fan blower, is built with an accurately formed blading system like a turbine pump. These machines have to be driven by steam turbines or electric motors to secure high rotative speed and are best adapted to locations where a very large amount of air is desired.

None of these machines, however, meets the demand for a rotary compressor of moderate size which can furnish compressed air at pressures from 10 lb. to 100 lb. per sq. in. and which will be readily portable. The limitations of speed of the reciprocating air compressor and the fact that it is generally an unbalanced machine, requiring substantial foundations, combine to make the positive displacement rotary air compressor a machine of great usefulness if it could be produced and sold at a reasonable figure and were capable of operating at reasonably high efficiency.

There have been occasional attempts to manufacture such positive displacement rotary compressors, but so far as we are aware, none of these have been permanently successful.

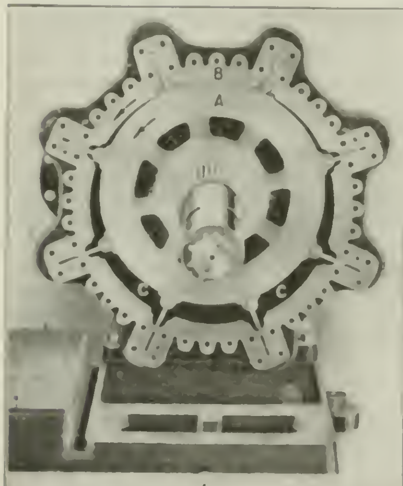
We illustrate herewith a new rotary air compressor designed on very novel mechanical lines, which seems to have considerable promise. The rock on which most designers of rotary air compressors have split has been the great friction between the closely fitting rubbing parts. In the air compressor here illustrated the inventor has overcome this difficulty by ingeniously contriving that both the rotor and its casing shall revolve in the same direction and at the same speed. Being on different centers, however, the rotor has an eccentric motion within its casing, and it is this eccentric motion which is utilized to effect the compression of the air.

The rotor shaft is hollow at each end and serves for the intake and discharge of air. It runs in roller bearings and in the machines now built is driven by a belt. The annular space between the two elements is divided into eight compartments or pockets by plates fitted to recesses in the casing and having shoes which bear against the face of the rotor. For each compartment the rotor has an intake and a discharge passage; these passages are radial and connect with the hollow portions of the shaft.

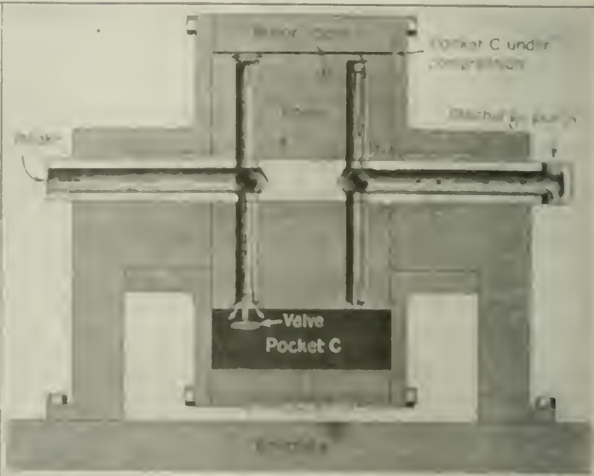
Fig. 1 is a section of the compressor, the rotor being in position for intake at the lower pockets and compression at the upper pockets, and it will be seen that the clearance or dead space in the latter position is very small. Fig. 2 is a diagrammatic longitudinal section. The rotating parts are balanced, and the sliding parts have relatively short travel and slow motion, thus reducing friction. The pressure in any one pocket during compression is greater than that in the following pocket, so that the sliding vanes are pressed against the walls of the recesses, thus preventing leakage.

The machine is air-cooled, the outer wall of each pocket giving a very large radiating surface in proportion to the volume of air under compression, while the entire outer surface of the outer case (revolving at high speed) forms effective cooling area. Lubrication is effected by a small geared pump.

Each intake valve is operated by means of a lever or link having one end attached to the rotor and the other end upon which the valve stem rests, riding upon a fixed cam. This construction is shown in Fig. 3. The discharge valves are operated automatically, by the dif-



1



2

A New Rotary Air Compressor

(Fig. 1 is a view of the interior and Fig. 2 is a diagrammatic longitudinal section.)

ference in presure. It is not practicable to operate these mechanically as the time of opening depends upon the receiver pressure, which is not a fixed quantity.

No packing is used between the end faces of rotor and case. The clearance between these faces is very

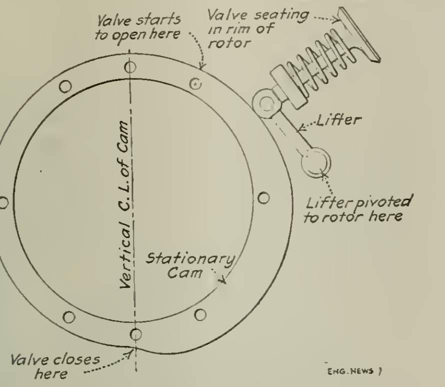


Fig. 3. Intake Valve and Valve-Operating Mechanism of Rotary Air Compressor

small, less than 0.001 in. Oil in very small quantities is fed into the intake to lubricate this surface and helps to seal it. The friction of these surfaces is extremely low because both are revolving in the same direction. The radial movement, or stroke, is small, being only 1½ in. on a rotor of 15-in. diameter.

The machine is at present built in one size only, having a displacement of 86 cu.ft. (or 75 cu.ft. actual delivery) when operating at 100-lb. pressure and at the maximum speed of 400 r.p.m. (giving 3200 compressions per minute). It requires approximately 20 hp. to operate the compressor under these conditions. The weight complete is about 1700 lb. It is claimed that tests thus far made indicate an efficiency at least equal to that of reciprocating compressors of about the same capacity. The rotary compressor is particularly adapted for use as a portable machine on construction work or steel erection, and in mines, quarries and industrial plants. One compressor has been in use for over a year.

This compressor is the invention of W. A. Hatcher, and is being manufactured by the Wernicke-Hatcher Pump Co., of Grand Rapids, Mich.

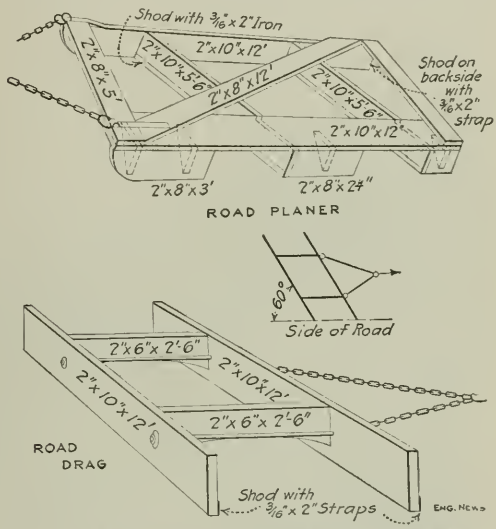
Road Maintenance in Minnesota

Under the road laws of Minnesota, it is the duty of the county commissioners of each county to maintain all state roads within the county, in accordance with the rules of the State Highway Commission, and 20% of the state-aid allotment must be expended for that purpose, with the due proportion of the county funds.

The maintenance may be done under the road-patrol system, the maintenance-section system or the road-drag system. The systems in question are outlined as follows in the rules prepared under the direction of Geo. W. Cooley, State Engineer, and John H. Mullen, Deputy Engineer of Roads:

ROAD-PATROL SYSTEM—One man to be appointed for a 5- to 7-mile section of road, and to be employed continuously from the opening of the season until final freeze-up. He will be furnished with shovel, rake, and such other hand tools as are necessary and also a wheelbarrow to cart surfacing material to fill holes, etc. The duties of the patrol will be to keep ruts from forming, remove loose stones from roadway and to keep surface of road in good condition. He will also be required to keep lines of drainage open and to keep weeds cut along the road. This system is applicable to macadam and well built gravel roads.

MAINTENANCE-SECTION SYSTEM—The state roads in a county to be divided by the County Board into sections of 20 to 30 miles (not necessarily one continuous stretch of road). The section to be in charge of a foreman, hired for the season, commencing as soon as work can be effectively done in the spring. This section foreman should be required to furnish hand tools and a team and wagon every working day, and the county to furnish him with a light grader, a road drag,



Road Planer and Drag Recommended for Road Maintenance Work by the State Highway Commission of Minnesota

slush scraper and plow. The duty of the maintenance-section foreman would be to keep lines of drainage open and weeds cut and to keep the surface of road in best possible condition at all times. The County Board should also authorize the foreman to enter into agreements with residents along the road to drag sections of it after very heavy rains, and also to employ extra men and teams as the occasion might require, but with a limit as to the expense incurred in this manner each month. This system is recommended to be adopted in most cases, as it will meet almost any condition.

ROAD-DRAG SYSTEM—A superintendent of dragging to be appointed by the County Board, who shall be given authority to contract with residents along the state roads to drag the same after each rain or whenever ordered by him. This superintendent also to have available a road grader with authority to employ an engine or teams to operate the machine when occasion requires. He should devote all his time to directing the work of general repair and maintenance, and see that the contracts for dragging are properly executed. Also to see that drainage lines are kept open and to arrange for cutting weeds along the state road. This system is especially applicable to the prairie and gumbo sections of the state.

Road Drags—A large amount of road maintenance by dragging is done in Minnesota, and a pamphlet issued by the State Highway Commission shows the recommended forms of drags. These are shown in the accompanying cut. It is stated that the drags which have proved most satisfactory are the home-made road-planer and the King road drag, and that the consistent use of these will insure a good road surface at all times.

New York Rapid Transit Railway Extensions*

By F. Lavis†

VI--Sewers, Pipes and Conduits

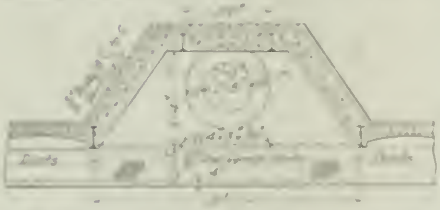
ELECTRIC CONDUITS

Four-way vitrified ducts with round holes (3½ in.) are used almost entirely for electrical conduits in the subway; they are located in the side bench walls, as shown in the various cross-sections, usually a double tier 5 high, making 40 single ducts.

The specifications require that the outside dimensions (of 4-way ducts) be not less than 9¼ in. or more than 10 in., with square outer lines and that the outside walls and webs be ¾ in. thick.

A jointed mandrel is used for laying and the joints are wrapped with muslin wraps soaked in cement grout. The mandrel is arranged so that the back part of it holds the joint last made, while the forward end holds the joint being made. One or two other forms of wraps have been tried but with little success. The whole bank of ducts is usually laid up, then the outer face of concrete, and top of the bench wall put in place. This is usually done before [illegible] to insure the stability of the duct bank.

Wherever it is at all possible, connections are made from all splicing chambers to the street, so that cables may



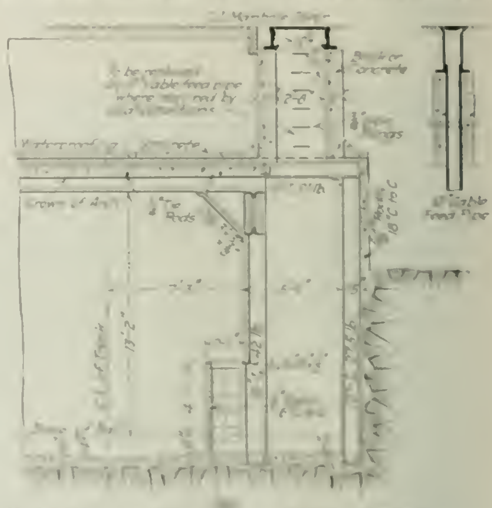


FIG. 24. HORIZONTAL SECTION OF SUBWAY WALL AT CABLE SPLICING CHAMBER AND VERTICAL SECTION THROUGH MANHOLE

be passed or withdrawn from the street surface, on account of the difficulty of handling them in the subway after operation has been started. Where space allows, a separate manhole is built from the splicing chamber to the street surface, but where this is not possible a [illegible] pipe is built in. The splicing chambers are, of course, set back and project outside the ordinary cross-section, a typical form being shown in Fig. 24.

The prices for these conduits as shown by contract abstracts [illegible] are approximately 10 to 15c. per lin. ft. of single duct.

EXISTING UNDERGROUND STRUCTURES

The construction of the subway, of course, necessitates many changes in the existing underground structures, such as sewers, water and gas pipes, electric conduits, etc. The isometric drawing, Fig. 30, shows conditions at Prince St. and Broadway on the line of the present subway as they existed 14 years ago. Since that time very great additions have been made to the underground street piping. The picture, however, gives some idea of what is found at many street intersections, though, as a matter of fact, the general appearance of one of these cross streets in the down-town section is more that of an intricate and confused jumble of pipes and cables of all descriptions instead of the orderly appearance of the drawing. Fig. 30 shows part of the plan of the intersection of Prince St. and Broadway and is fairly typical of conditions in the lower part of the city.

It would seem at first thought that certain large trunk sewers and other important subsurface structures might have considerable influence on the location of the rapid-transit lines, but it has generally been found easier or less costly to change these than to change the position of the subway. This latter, of course, is usually located as near the surface as possible, and any change would mean lowering it, which would be undesirable from the standpoint of those who have to use it, and, of course, would mean increased excavation with proportionately greater expense, so that generally speaking, the subway is located regardless of any of these structures and these latter moved if necessary. There are a few instances where it has not been practical to move some of the large trunk sewers, and these will be noted further on.

The work connected with the changes, etc., required in the existing underground structures is all taken care of by two divisions, each covering the whole city in its own special department. One under C. N. [illegible] has charge of the relocation of all pipes, conduits, etc., and the other under L. D. [illegible] has charge of all the sewer relocation, design and reconstruction. The importance of this part of the work may be gathered from the fact that there are employed in these two departments alone, taking

*Copyright, 1914, by F. Lavis.

†Consulting Engineer, [illegible] New York City.

care of work in a way entirely outside of the main construction, some 150 engineering assistants, the changes in the sewers alone involving an expenditure of $6,000,000 to $7,000,000 and the construction of some 60 miles of new sewers.

Gas Mains—One of the most important developments in taking care of the pipes, etc., on the new work has been the bypassing of all the gas mains, that is, the construction of new pipes for gas, on the surface of the street and the stoppage of the flow in the pipes underneath before commencing the excavation. This, of course, involves also new temporary house connections as well, but the danger of the accumulation of gas underneath the decking is thereby eliminated. The very great danger from this source was demonstrated by the recent explosions at 23rd St. and 5th Ave. (Eng. News, Mar. 12, 1914), which while generally attributed by the public press to the subway construction, were caused if at all only very indirectly by this work. The following description of the method of dealing with the gas mains is contributed by C. N. Green.

"The present specifications for subway construction call for the street to be planked or decked over in the business sections or where traffic is heavy, so that business may be carried on as usual and with as little inconvenience to the public as possible. This decking then forms a temporary street surface under which the excavation is carried on. In time dirt and the sweeping of the street make the decking tight and prevent a circulation of air that would free the excavation of gas if a main should leak.

"Cast iron is used for gas and water mains when they are laid underground for the reason that it lasts much longer under such conditions than wrought iron. It is difficult, however, to keep the lead-calked joints of such pipe tight even when they are undisturbed, but when they are moved in excavating and hung up on the timbering, some joints are sure to be strained and begin to leak.

"All gas mains are, therefore, 'killed' where they would be underneath a closely decked street, except in rare cases where small transverse cast-iron mains are replaced under the decking by wrought-iron pipes with screw connections. A temporary system of wrought-iron pipes or bypasses for gas distribution is laid in the gutters and connected with the live mains in the transverse streets and the house and street-lamp services are transferred from the cast-iron mains below the street surface to the temporary system. There is then no live main or pipe containing gas below the street surface." (Figs. 26 to 29.)

"An 8-in. gas pipe broken off in the excavation might, under existing conditions, deliver 1000 cu.ft. of gas per minute. A 10% mixture of gas and air will perhaps not always produce a maximum explosive effect, but this is assumed for convenience and is very near a maximum. This would make 10,000 cu.ft. of explosive mixture per minute. A subway cut 25 ft. deep, 60 ft. wide, would contain 390,000 cu.ft. in a city block, so that theoretically in 39 minutes the block would be filled with an explosive mixture. This, of course, would not be absolutely true as the gas would not diffuse itself with such rapidity and the mixutre would be higher in gas near the break in the main and perhaps be too low in gas at the farthest point to explode, if the mixture should explode, however, the gas would burn where there is an excess and probably set fire to the timber with results as disastrous as the explosion itself.

"Gas mixed with air forms a very explosive compound which only needs a spark to ignite it. This spark might be furnished by the underground trolley of the surface

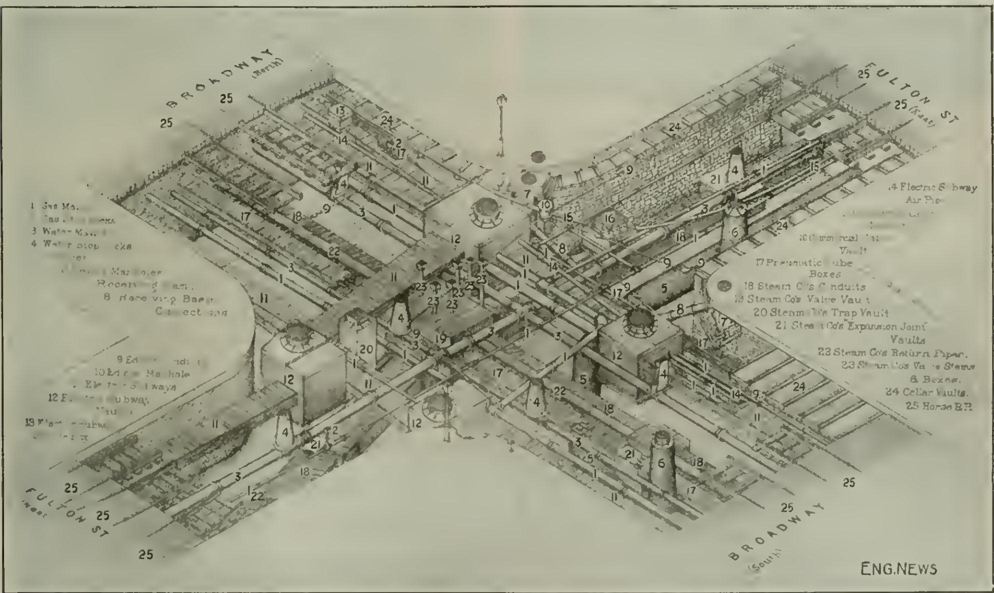

Fig. 25. Isometric View of Underground Piping at the Intersection of Broadway and Fulton St. in 1890

subway, in case of the numerous cables exposed during the construction by a lighted match thrown away, by fire engines, by the shoe of a horse, or by blasting, etc. The violence of such explosions has been frequently shown when manhole heads have been blown into the air, and by numerous sewer explosions which have occurred in the last few years. Philadelphia and Boston had examples in the construction of their subways and various minor instances have attested to the power of such a mixture.

Fig. 26. A Temporary Gas Main Run Next the Street Curb

"Knowing the danger from gas, both the gas company and the engineers of the Public Service Commission have taken every precaution to avert it. It was, therefore, decided not to leave any cast-iron mains, carrying gas, under the decking unless properly ventilated by means of gratings or protected by watchmen. Where mains crossing the subway excavation could not be cut out of service temporarily, wrought-iron pipe bypasses were to be built over the street or in the case of small pipes carried across under the decking. All connections between the cast-iron mains and the wrought-iron bypasses were to be carried far enough back into solid earth to avoid the danger of breaking off the pipe if a slide or cave-in should occur.

"In mains to be 'killed,' the flow of gas was first stopped by inserting bags in the pipe and readings were taken to see if the pressure prescribed by the Public Service Commission could be maintained. The pressures were

Fig. 27. Overhead Gas Main at Lexington Ave. and 112th St.

taken continuously for several days and if these readings were satisfactory the longitudinal mains were cut off and capped at intervals of two blocks. In the meantime the bypass pipes were laid in the gutter and connected up. These were 6, 8, 10 or 12 in. in diameter, depending on the requirements of the different districts. Depending on conditions, one or two lengths of pipe were used to carry back in the transverse street and the turn at the curb was made with a pipe bent to fit the radius of the curb corner, Fig. 26. The pipes in each transverse street

Fig. 28. Overhead Gas Main on Lower Broadway

were then cut and capped about 10 ft. back of the sheeting line on both sides of the proposed excavation. Connection was then made with the largest pipe underground on each side of the street and the bypass continued underground across the transverse street.

"Generally there are from one to five pipes on each side of the transverse streets. Where there is more than one

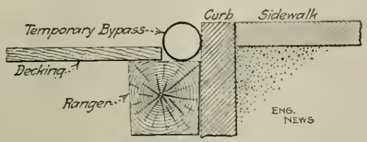

Fig. 29. Typical Method of Placing Gas Main at Curb

pipe on the same side of the street, each is connected back of the caps with a 1½-in. circulation connections, the vertical legs of which are tapped into the top of the pipe.

"In laying the first bypasses little attention was paid to the necessity of keeping the tops of the pipes level with or below the curb. As a consequence, numerous accidents occurred, due to persons slipping or tripping over the pipe. In one instance where the pipe did not lie close to the curb, a boy's leg was broken by being caught between it and the curb. Now all pipes are laid close to the curb, with the top not higher than the curb even if necessary to remove the gutter stones, and the remaining space is filled with concrete.

"Extra heavy wrought-iron pipe has been used generally, so that when the bypasses are moved the pipe can be used to relay the cast-iron mains over the subway. The gas company has found this desirable, as the vibration from the passing trains loosens the calking in cast-iron pipes.

"In Lower Broadway from Canal St. south are two mains 16 and 20 in. in diameter, respectively, supplying the lower part of the city. These mains were bypassed during the building of the subway from Vesey St. to Canal St. Wrought-iron pipes with flanged connections were laid about 14 ft. above the sidewalk. The trestle bents were so placed as to avoid entrances and interfere with business as little as possible. At cross streets where trestle bents could not be erected, the pipe was trussed with wire rope anchored to the pipe with clamps.

"In 138th St. are one 16-in., one 20-in. and one 24-in. gas mains forming a crosstown connection between the works and the lower west side of the Bronx. As these were within the sheeting lines, they were killed, and to take their place two 24-in. riveted steel pipes were laid on trestles, one on each side of the street.

"In various locations are large feeder or pumping mains crossing the line of the subway, and these mains generally were bypassed overhead, giving about 14 ft. clearance for the street cars and other vehicles. A description of one would be typical of all. Fig. 27 shows the bypass for the 36-in. main crossing Lexington Ave. at 112th St. The bypass pipe is a 30-in. wrought-iron riveted pipe carried on two gallows-frame supports back of the building line in the side street. Between these frames the pipe is suspended from two wire ropes carried over the gallows frames and each anchored back to a deadman. The deadman consisted of an inclined I-beam carried well below the street surface and its lower

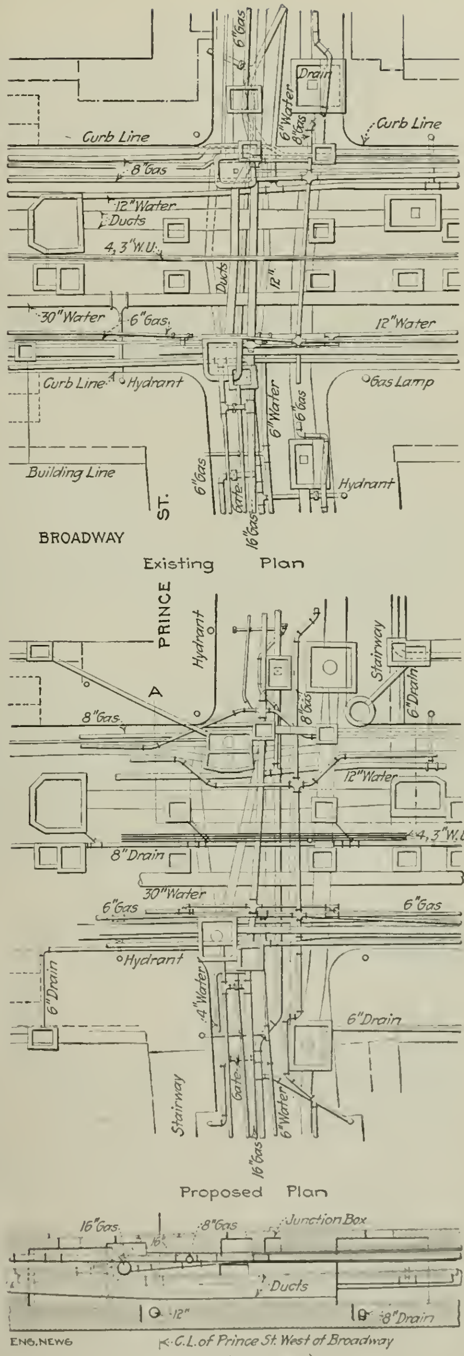

Fig. 30. A Typical Rearrangement of Underground Piping at a Street Intersection. Old and New Plans of Underground Piping at Broadway and Prince St.

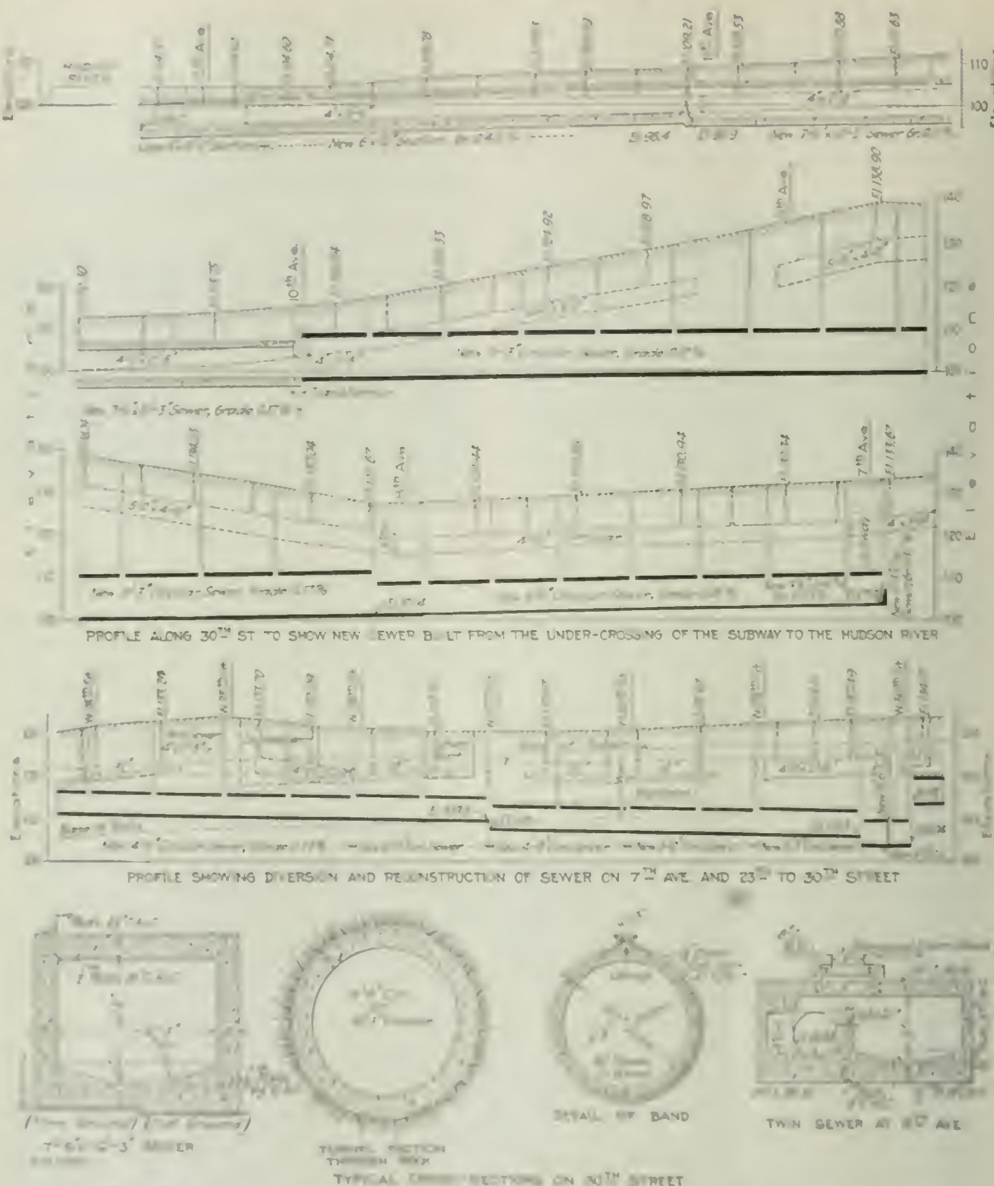

FIG. 10. TYPICAL SEWER RECONSTRUCTION WORK ON 30TH ST. AND SEVENTH AVE.

and embedded in a block of concrete. The main in the street was bagged off, the pipe cut and a three-way and valve inserted at the end of the pipe. This operation was repeated on the other side of Lexington Ave. The bypass was then connected to the three-ways on either side of the section, the bags removed and the valve closed to throw the gas into the bypass and cut the main underground.

"The cost of bypassing service mains, using 6- or 8-in. wrought-iron pipe laid in the gutter, varies but little from $10,000 per mile of street bypassed. The distribution mains requiring 3- to 20-in. bypasses in general run across the island from the east to west, thus crossing most of the subway lines nearly at right angles. The cost of carrying a distribution main across the street we found may vary from $1000 to $10,000, depending on local conditions. The average cost, however, should be about $2500.

"After the construction of the subway and the restoration of the underground pipes, the bypasses are removed and the street restored to its original condition."

Sewers.—The work of the department in charge of the

necessary sewer relocations commences as soon as a new route is proposed, as, although the subways are generally located with little regard for existing subsurface structures, minor changes and adjustments in elevations and gradients are quite often found to be desirable. General studies of the sewer situations are, therefore, necessary from the beginning. The sewer changes are worked out in consultation with the city authorities and the plans are made part of the contract drawings. This same department makes the preliminary studies, final plans and supervises construction.

Generally the existing sewer line is located in the center of the street. The construction of a subway therefore usually involves its complete elimination, and the substitution of two lines, one on either side. In Manhattan also the main trunk sewers and intermediate main lines are generally located in the cross streets running east and west to the Hudson or East River. The construction of a subway on one of the main north and south avenues therefore cuts these all off, as they are nearly always located below the level of the roof.

the surface of the street was raised 5 ft. to enable the subway to pass over the top of the sewer.

Generally speaking, however, the large sewers where they have been encountered have been passed under the subway by means of siphons, and while this is not generally considered desirable for sewers, those so far built seem to be working satisfactorily. The general principle on which they are designed is much the same for all; that is, a comparatively small pipe for the so called "dry-weather" flow, with one or two larger pipes for the storm flow. The plan and section shown, Fig. 32, of the siphon at 110th St. and Lexington Ave. is quite typical. Most of the siphons have been built with easy slopes for the drop or rise, but in one instance in Brooklyn, at Hudson St., perpendicular raises were required on account of the cramped conditions. In this case a wide, very shallow additional safety overflow was provided over the roof of the subway.

Cross-sections of particular forms of construction not usually met with in sewer work, but required by the exigencies of limited clearance in many cases in con-

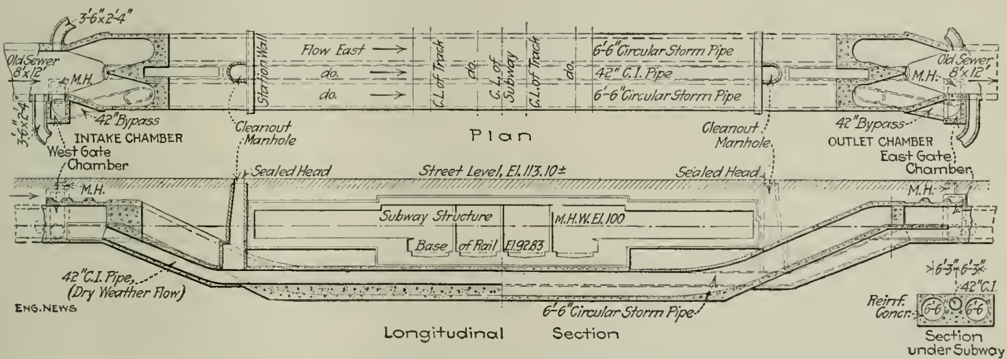

FIG. 32. INVERTED SIPHON CARRYING SEWER UNDER SUBWAY AT 110TH ST.

On what may be referred to as the down stream side of the avenues the problem is usually comparatively simple. A new line is laid between the subway and the buildings, connecting at the cross streets to the existing sewers, which, however, of course only get part of their former flow. On the up stream side, however, not only do the buildings adjacent to the subway have to be taken care of, but also the flow from the cross drains which have been cut off. The least important of these cross sewers are, therefore, collected in a main laid parallel to the subway and carried to some convenient crossing point, where either the subway can be lowered, to pass the sewer over the top, or where topographical conditions permit the sewer to go under and continue with sufficient fall to the point of discharge into the river. The conditions at 30th St., New York, are quite typical of this condition, Fig. 31. The construction of this one line, giving a new outlet all the way to the North River, cost over $500,000.

In a very few instances there have been large trunk sewers which could not be changed and which have necessitated a very considerable adjustment of the gradients of the subway to enable the line to pass them. At Canal St. and Broadway and at Duane St. and West Broadway, Manhattan, the subways were depressed to go under the sewer, while at Brook Ave. and 138th St., in the Bronx,

nection with the subways, are shown in Fig. 33. An interesting temporary expedient was adopted on the Fourth Ave. subway in Brooklyn. At one place on this line it was necessary to take care of quite a large volume of sewage until such time as a new relief trunk sewer could be built by the city. The subway at this point was built for six tracks, so one whole bay at one side for a length of 2200 ft. was isolated by being walled in, waterproofed and turned into a sewer until such time as the relief sewer was built.

The Duane St. sewer in Manhattan is typical of certain conditions which have to be met and where advantage was taken of the peculiar topography of New York and the long established habit of drainage into the rivers on both sides of the city. The drainage from Centre St., through which the so called Loop line runs from Duane to Delancy, was to the East River. This was cut off by the construction of the Loop, which was too deep to permit the construction of the sewer underneath, so a deep-level sewer was built under the original subway, through Duane St. to the North River, thus reversing the flow from what was formerly the up-stream side of Centre St. It is this new sewer that the Seventh Ave. route in West Broadway has to go under, as referred to above.

Nozzle Testing, Fitchburg, Mass., Sewage Treatment Plant*

The problem of finding an efficient method of uniformly distributing sewage over the surface of a rock filter is one which has been the subject of extensive studies.† Severe winter conditions preclude the use of any traveling distributor, and the method generally employed is the discharge in the form of a spray through some type of fixed nozzle operating under a varying head.

No nozzle has yet been used that will give a uniform distribution in practice. Some are better than others, and it has been the purpose to test the types of nozzles now on the market, and from the result of these experiments to select a nozzle and design a tank, which combined, will effect the most uniform distribution. These tests to the first of May, 1914, numbered over 1000.

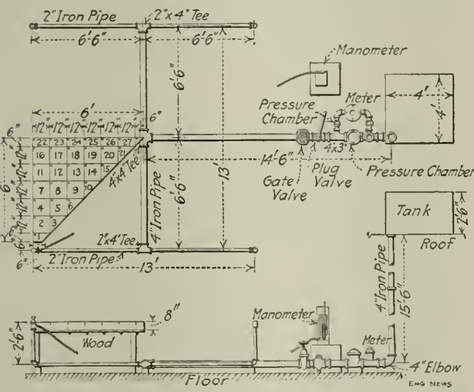

FIG. 1. NOZZLE-TESTING APPARATUS, SEWAGE-TREATMENT PLANT, FITCHBURG, MASS.

The plant for testing the various nozzles was set up in a garage connected with the sewer department building. The first experiment showed that satisfactory results could not be readily obtained by studying the discharge of a single nozzle; consequently, the plant was so arranged that the distribution would be analogous to that obtained in practice if the nozzles were placed on the corners of squares or interlocking hexagons whose sides were 13 or 15 ft.

Fig. 1 shows the apparatus when set up to study the distribution of nozzles set on the corners of a square with a side of 13 ft. The pan and distributors were later extended to study the distribution of the same nozzles spaced 15 ft. Only those nozzles designed to throw a spray over a square area were tested with this form of apparatus.

Three nozzles on the apices of an equilateral triangle are sufficient to show the distribution as effected by nozzles placed on the apices of interlocking hexagons. Fig. 2 shows the apparatus as used when the nozzles were considered as placed on the apices of hexagons with sides of 13 and 15 ft. Only those nozzles which throw a spray over a circular area were tested with this scheme of spacing.

For determining the head under which a nozzle operates, the mercury pressure gage, shown in Fig. 1, was later replaced by a water column, which proved far more satisfactory. It was found that for measuring the actual discharge in gallons of a given nozzle at a given head, it was more accurate to plug all risers except one and insert a small meter in a 2-in. distributor, than to use the large meter for all nozzles. Consequently, the large meter shown in the sketch was removed. The piping was arranged in all cases as symmetrically as possible, and every precaution was taken so that the pressure on all nozzles was equal.

For collecting the discharge and studying the distribution of those nozzles designed to throw a square spray, a 45° galvanized-iron pan representing one-eighth of a square inclosed by the nozzle was used. The pan was divided into sections as shown in Fig. 1. Each section is drained by ½-in. pipe about 3 in. long soldered to one corner and closed with a rubber stopper during the test.

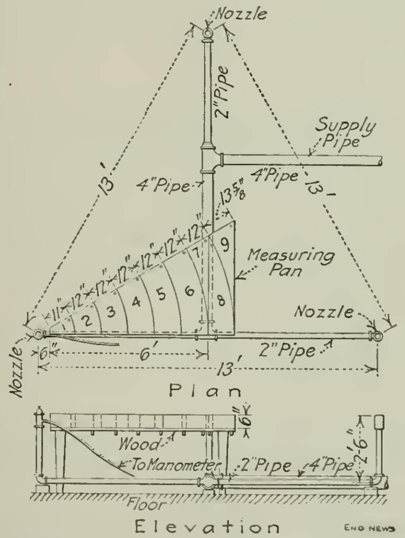

FIG. 2. TESTING APPARATUS FOR CIRCULAR NOZZLES

The whole pan rests on a wooden base and can be moved readily.

For collecting the discharge of those nozzles which throw a circular spray, the pan shown in Fig. 2 was designed. It was later divided into smaller sections along the line of radii drawn from the center to the desired points on the arcs. It covers one-twelfth of the total area dosed by each nozzle when the hexagonal spacing was used.

Using Fig. 1 as an illustration, a typical test was conducted as follows: The tank on the roof was filled with city water by means of a hose and, with the water still running, the pan unstoppered, and the plug valve open, the gate valve was regulated to give the desired head as indicated by a water column.

The plug valve was then closed and the pan stoppered.

*From the Seventh Semiannual Report of the Sewage Disposal Commission of Fitchburg, Mass.; for description of Fitchburg Sewage Treatment plant, see "Engineering News," June 5, 1913, p. 1176.

†For a description of the sprinkler testing apparatus used at the Massachusetts Institute of Technology in 1907, see "Engineering News," Jan. 9, 1908, p. 28; Aug. 20, 1908, p. 199.

At a signal time the plug valve was opened quickly and the water allowed to discharge through the nozzles under constant head for 5 or 2 min. At the end of the time period the plug valve was closed quickly and the amounts collected in the various pan sections measured with a properly graduated cylinder.

The discharge of each type of nozzle was determined separately with a small meter, as noted previously. Consequently, the amount collected in the pan should be one-eighth of the total discharge for any particular head. Any difference at low head would be due largely to eccentricity of the nozzle spindle or variation in the deflecting cone, while at higher heads, the effect of overlapping would be apparent. It was for the purpose of best studying this overlap that the battery of nozzles, instead of the single nozzle was used.

The amounts collected in the pan sections and the meter readings were recorded on special blanks and all subsequent calculations were made from these data. Duplicate or triplicate tests beginning at 2-ft. head and ending with 9-ft. head constituted a series.

Two makes of square type and two of circular type of sprinkler were studied. The work was discontinued through the cold weather, but was resumed in early spring, when a special nozzle designed by the department was studied.

Ladder Dredges with Side Ladder Frames

A type of ladder dredge which is used extensively on the Ohio River, is peculiar in having the ladder frame carried at the side (and clear of the hull) instead of in a central well in the hull. These machines are employed largely in obtaining sand and gravel from the river bed, and are frequently of rather rough-and-ready construction.

The left-hand view, in Fig. 1, shows one of these dredges built by the Missouri Valley Bridge & Iron Co., of Leavenworth, Kan., and now in use by this company on its contract for the construction of Dam No. 14 in the Ohio River at Woodland, W. Va. The arrangement of the machinery, etc., is shown on the plan, Fig. 2. The hull is 24x[illegible] ft., and of very shallow draft. The deck extends on the ladder side to support the ladder and protect it from gravel barges lying alongside. A 10-hp. single-cylinder marine engine is belted to a countershaft from which are driven the tumbler shaft of the ladder (by belt), the pump shaft (by gearing), and the sand screen shaft (by sprocket chain).

The ladder is 63 ft. long, and is made of two timbers 6x18 in., spaced 39½ in. apart, trussed laterally and vertically, and having cross struts about 6 ft. apart. It is pivoted around the main shaft (about 17 ft. above the deck) by means of boxing bolted to the timbers.

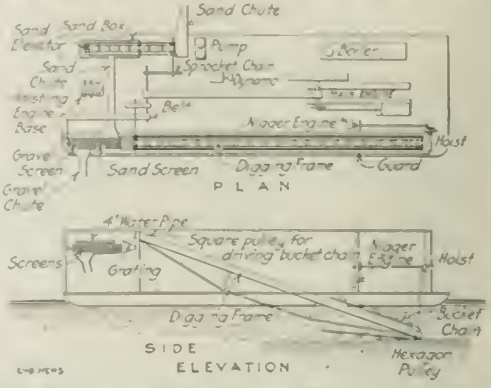

Fig. 2. Plan and Elevation of Side-Ladder Dredge

Keyed to the shaft is a square tumbler, each side of which is equal in length to that of one link of the bucket chain. The lower end of the ladder has a large hexagonal idler pulley, and to this end is attached a hoisting chain for raising and lowering the ladder. The chains wind on a large drum, operated by a small reversing engine through bevel gearings.

The ladder carries an endless bucket chain made up of link bars about 12 in. long, to which the digging buckets are bolted 5 ft. apart. Each bucket holds about 1 cu. ft. As the buckets pass over the tumbler on the main shaft, they dump the dredged material on an inclined grating, from which the larger stones roll back into the water, while the material passing through goes to two inclined cylindrical screens. The first or sand screen is of ¼-in. mesh and about 5 ft. long, following that is the gravel screen, of 2 in. mesh and about 4 ft. long.

The material entering the screen is washed by jets from a perforated 1-in. pipe, placed immediately over the screen, and these jets serve also to keep the meshes free. The finer material passing through the sand screen is led by a chute to a box on the other side of the hull. The material passing through the gravel screen is led by another chute into barges on the ladder side of the dredge. Any stones too large to pass through the screens go overboard. The sand-collecting box is about 4x12 ft.,

Fig. 1. Side-Ladder Dredges for Excavating Sand and Gravel in the Ohio River

(The dredge at the left, operated by the Missouri Valley Bridge & Iron Co., has a hull [illegible] ft. and a ladder frame [illegible] ft. long. The dredge at the right [illegible] has a hull [illegible] ft. and a ladder frame 75 ft. long.)

6 ft. deep, with a small weir on one side for the water to escape, carrying with it the dirt, clay or floating material. A bucket elevator takes the sand from this box and discharges it into a chute leading to barges.

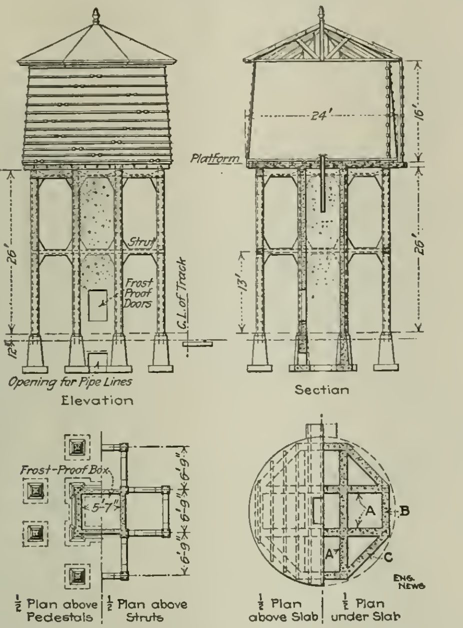

Fig. 1. Standard Reinforced-Concrete Tower or Substructure for 50,000-Gal. Water Tank; Erie R.R.

A two-drum hoisting engine, supplied with steam from the boiler, is used instead of the crabs and capstans usually employed for raising spuds and handling barges. The spuds are raised by cables running to the drums, while the barge lines are moved by the winch heads. The crew consists of engineman, fireman and two deck hands. In ordinary digging the machine will excavate about 50 yd. of sand and gravel per hour.

A larger dredge of the same type is shown at the right in Fig. 1, and is one of two used by the T. A. Gillespie Co., of Pittsburgh, Penn., on its contracts for lock and dam work on the Ohio River. The ladder is 75 ft. long, 4 ft. 6 in. wide over all and carries 28 buckets of 4½-cu.ft. capacity, made of ⅜-in. steel with reinforced lips. The ladder chain makes a complete revolution in about four minutes. The sand conveyor has 16 buckets of 3 cu.ft. capacity, and its chain makes a complete revolution in about 1¾ minutes.

This boat carries two marine boilers, one main engine (10½x36-in.), which operates both the ladder chain and the sand elevator, two capstan engines to operate the ladder hoists, and two double-spool steam capstans; also engines for operating the spuds or anchors, barges, lines, etc. The hull is 120x28 ft. and 5 ft. deep, with a draft of about 2 ft. when coaled and under steam. The weight of the ladder is counterbalanced by placing the boilers, sand bin and coal bunkers on the opposite side of the boat.

The dredge can operate successfully in water 30 ft. deep. Its capacity depends to a large extent upon the material to be handled, but for ordinary purposes it is estimated at 400 yd. per 8-hr. day. This boat was built by the Dravosburg Dock Co. and the machinery was manufactured and supplied by the Goodman Engine & Machine Co., of Pittsburgh, Penn. The total cost ready to operate was about $20,000 for each of the Gillespie Co.'s dredges.

Concrete Tower for Water Tank: Erie R.R.

The towers supporting railway water tanks are usually of timber or steel construction, but concrete has been used in a number of cases and the accompanying cuts show the standard design of the Erie R.R. for a reinforced-concrete tower for 50,000-gal. tanks, the tank itself being of wood. Fig. 1 shows the general design, while Fig. 2 shows some of the details.

There are four inner columns 8x8 in. and eight outer columns 14x14 in., with horizontal connecting struts at mid-height, except that these may be omitted when the height is less than 20 ft. The inner columns are built integrally with 8-in. curtain walls forming a frostproof air chamber around the pipes. At the top there are transverse beams and an octagonal ring girder 16 in. deep, supporting a 10-in. concrete slab 23 ft. diameter. On this are placed 6x6-in. timber sleepers to support the bottom of the tank. The slab is reinforced by 70-lb. rails, laid 2 ft. c. to c. All members have 1-in. chamfered edges.

Gravel concrete is used. The foundations are designed for a load of 30 tons per column, the foundations being

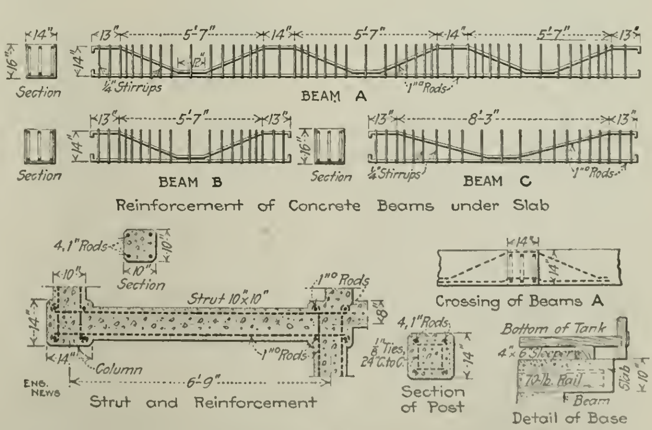

Fig. 2. Details of Reinforced-Concrete Tower for Water Tank

carried to such depths as may be made necessary by the character of the soil. These structures are built under the direction of R. C. Falconer, Superintendent of Construction, Erie R.R.

Field and Office

Bricklaying Costs for 5 to 10-Ft. Brick Sewers at St. Louis, Mo.

By C. L. French*

An attempt to standardize bricklaying methods in sewer construction so as to secure the greatest efficiency at each step of the work was recently made in St. Louis. The contract on which this attempt was made was for the [illegible] section of the Glaise Creek Joint Sewer, which was carried out by the American Contracting Co. This contract consisted of 7510 ft. of brick sewer, varying from 5 to 10 ft. in diameter and from 13 to 18 in. in thickness. The total amount of brickwork was 10,261 cu.yd., consisting of 9600 cu.yd. common and 661 cu.yd. of vitrified brick masonry (to line the invert for the dry-weather flow).

It was found that by planning the work so that a certain number of bricklayers could be constantly employed, the best men could be kept. The importance of this feature is nearly always underestimated by contractors. The difference between the work done by a good man and an average man is at least 10%, and where full time can be made the very best men are obtainable.

The next step was to get the maximum of work from the bricklayers. This meant not harder work, but eliminating lost motion. The essentials were proper working room, sufficient materials in the right place, and safe working conditions. Solving each of these problems required much experiment. Too many or too few bricklayers in a given space was found to be equally expensive. Materials in the right quantity, just where needed, make it unnecessary for a $[illegible]-a-day bricklayer to wait for a $2.50 laborer.

The principle of "safety first" was found to be of more importance than merely a humanitarian measure. Accidents demoralize efficient work, and a little extra care and expense along this line will more than pay for itself. For example, brick baskets were used instead of slings, and only material immediately to be used was allowed on scaffolding.

The elimination of useless labor was one of the greatest problems. Mortar was mixed by machinery at a cost of less than [illegible] per cu.yd. for power. Great care was taken to have the mortar of just the proper consistency. It was found that, everything else being equal, the day's work could be increased [illegible] by having the mortar exactly right all the time. The mortar was dumped directly from the machine into barrows and then passed into chutes. Thus the helpers had only to dump the mortar into the mortar boxes. Mortar mixers and mortar tenders were thus eliminated. Materials were stored as close to the ditch as possible and in the same quantity as would be used in that length of sewer.

The job was started Nov. [illegible], 1913, and finished Aug. [illegible], 1914.

The cost data are based on the following prices for labor and material delivered:

Bricklayer	$1.12½ per hr
Laborer	0.31 per hr
Brick, common	8.50 per M
Brick, vitrified	16.50 per M
Cement	1.40 per bbl
Sand	0.85 per cu.yd.
Electricity	0.10 per kw hr

The constants for each cubic yard of brick were:

430 common brick at	$8.50	$3.66
338 vitrified brick at	16.50	5.58
0.65 bbl. cement at	1.40	0.91
0.35 cu.yd. mortar at	0.85	0.30
0.10 kw hr. at	0.10	0.01

The mortar was 1 part cement to 3 parts sand

This makes the material cost $4.88 per cu.yd. for common and $6.80 per cu.yd. for vitrified-brick masonry.

The monthly records were as follows:

	Cubic yards laid			Cost per cu.yd.		
Month	Common	Vitrified	Per day of 8 hr. per bricklayer	Labor	Total, common	Total, vitrified
Nov., 1913	768	53	9.3	$2.2[illegible]	$7.11	$9.[illegible]
Dec., 1913	1444	99	10.8	2.02	6.90	8.82
Jan., 1914	1290	87	11.7	1.90	6.78	8.70
Feb., 1914	60	4	12.0	3.00	7.88	9.80
Mar., 1914	116	29	10.5	1.90	6.78	8.70
Apr., 1914	1132	78	11.8	1.78	6.66	8.58
May, 1914	970	68	11.0	2.24	7.12	9.04
June, 1914	1419	70	9.9	2.26	7.14	9.06
July, 1914	1912	133	12.6	1.77	6.65	8.57
Aug., 1914	619	41	8.5	2.65	7.53	9.45
	9600	664				

Average cu.yd. per bricklayer per day of 8 hr.		$11.0[illegible]
Average labor cost per cu.yd.		2.02
Average cost of brickwork per cu.yd.	common	6.90
	vitrified	8.82

The high cost of labor in May is due to tunnel work at night, when double time was paid to bricklayers. The high cost for June is due to bad working conditions, where frequent cave-ins caused much delay. The last month's figures are not significant, as the best men had left for other jobs and lots of cleaning up was necessary.

*[illegible] Engineer to Sewer Commissioner, [illegible] St. Louis, Mo.

Adjustable Orifices for Measuring the Flow of Sewage

By John H. Gregory*

The control and measurement of the flow of small volumes of sewage is somewhat troublesome and the writer was especially interested to read the article by Geo. T. Hammond (Oct. 22, 1914, p. 836), on the use of calibrated orifices for the purpose at the Brooklyn Sewage Experiment Station. The writer was confronted with a similar problem in 1904 when designing the sewage-testing station at Columbus, Ohio,[1] and after careful consideration, adopted adjustable brass orifices as being the simplest and most practicable device for measuring and regulating small volumes of flow.

The Columbus orifices, as are the Brooklyn orifices, were used in connection with a box in which the sewage was maintained at a constant level but differed from the Brooklyn orifices in that they were adjustable horizontally instead of vertically and were set inside of the box, with the inside face of the orifice flush with the inside of the box, instead of outside of the box as at Brooklyn. Also they were so constructed that all four edges of the orifice were in the same plane.

*Consulting Engineer, 170 Broadway, New York City.

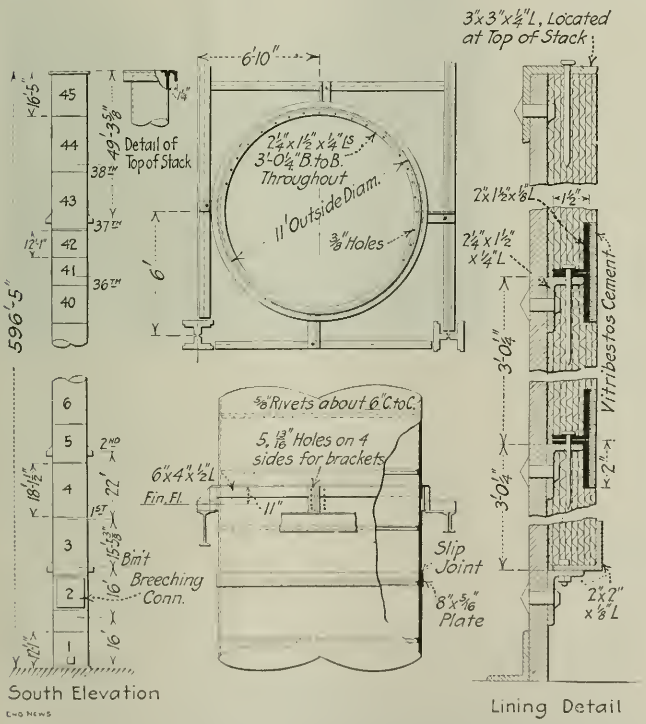
[1]"Engineering News," [illegible]

The orifice was adjusted by means of a handwheel carried on the end of a stem which projected out through a threaded nut set in the side of the box. The opening of the orifice and corresponding flow was obtained by determining, by means of a scale, the position of the wheel with reference to the nut.

The principle involved in the Columbus and Brooklyn orifices is the same, the differences between them being in the details of construction and setting. These differences are only of minor importance, as orifices of this kind should be calibrated if the most accurate results are desired.

Largest Interior Steel Stack, Equitable Building

The largest stack included in the construction of any office building to date, is the lined-steel stack of the new Equitable Building, New York City. It is 11 ft. in diameter by 596 ft. 5 in. high, plates $\frac{5}{16}$ in. thick. The stack is supported on the steelwork of the building at every other story. Just below each point of support is a slip-joint to allow for expansion. The general design of the stack, the method of anchoring to the building steel, design of the supporting bracket, type of slip-joint, the method of holding the stack lining in place, and other features of the construction are shown in the accompanying drawing.



General Design of Equitable Stack

Erection of the Stack—The steel sections, which vary in height from 12 to 18 ft. ½ in., were trucked from lighters on West St. to the front of the site on Broadway. As a problem in transportation, it is interesting to note that only one street was found which gave sufficient clearance throughout its length to permit the sections being carried directly to the site, without being unloaded and rolled under elevated railway structures. The city requires that all structures over streets shall have a height of at least 13 ft. above the pavement. In this particular instance, the loaded truck required a clearance of 16 ft.; a depression on Morris St., under the elevated-railway structure gave a clearance of 16 ft. 4 in., and here the load could get through under the structures on Greenwich St. and Church St.

At the site, a section was lifted from the truck, on Broadway, by a derrick, and deposited on the steelwork above. A second derrick picked up the section and swung it into the stack shaft. An ordinary derrick gang was able to handle a section.

The stack rises from a concrete base at the sub-sub-basement level. Its rate of erection was dependent upon that of the steelwork of the building.

Lining Stack—The lining of this stack differs from that of most interior stacks in that it extends the entire length.

The lining used (J-M Vitribestos) is formed of alternate layers of plain and corrugated asbestos board coated with a supposedly vitrified compound. It comes in curved slabs about 40x35 in. in plan by 2 in. thick. The slabs are sawed to fit between angle irons which encircle the inside of the stack 3 ft. apart, and they are held against the stack by angle clips fastened to the circular angles by nails, and the joints closed with Vitribestos cement, as shown in the vertical section sketch.

Application of the lining was not commenced until the stack steel had risen 26 stories. A piece was then cut from the section at the 12th floor, large enough to permit the entrance of workmen and material. After all the slabs were placed from the 12th to the bottom, the joints were cemented. An opening was then made in the stack at the 24th floor and the above process repeated. Later the cut pieces of steel plate were welded back in place.

The lining was applied by two men on a scaffold suspended in the stack. A third man prepared the cement and lowered it and the slabs, etc., down to the workmen. The work advanced at the rate of about 20 ft. per day, which was considered very satisfactory progress.

Personnel—The steelwork of the stack was furnished by the Dover Boiler Works, and erected and lining applied by the Thompson-Starrett Co. (George Simpson, Chief Engineer; H. S. Gardner, Superintendent of Construction), New York City, general contractor for the building. The lining was furnished by the H. W. Johns-Manville Co.

Notes on the Computation of Boundary Surveys

By A. W. B[illegible]*

Computations for boundary surveys should be put on quadrille ruled paper; that is the results, the logarithmic work not being saved.

In finding the latitude and departure of a course the work is simplified by writing the *log distance* in the center with the *log cos* and *log sin* above and below it, additions being made at both top and bottom. When the latitude and departure of a course are given and the bearing and distance are required, the *log tan* of the bearing is found by subtracting the *log latitude* from the *log departure*.

Then either the *log sin* or *log cos* of the bearing is looked up (whichever is greater; the larger function is always in the right-hand column), and subtracted from the *log latitude* or *log departure* (whichever is greater) which gives the *log distance*. The reason for doing this is that the percentage of error of the smaller function, taken together with the shorter side, is relatively so great as to make it less reliable in determining the length of the hypotenuse.

Searles's five-place *log* tables are nearly as accurate as Vega's for single minutes only, and much quicker. [illegible]'s traverse tables are very quick for finding latitudes and departures, but cannot be used for the reverse operation. If very much of this kind of computation is done, the most efficient way is with five-place tables of natural functions and a computing machine, which will save about 50% of the time. All computations should be checked either directly or by the reverse operation.

With angles read in the field to minutes, and distances to 0.01 or 0.05, the final courses should not be computed any closer than those measured; to do so only gives a deceptive implication of greater accuracy.

It will often improve the closure to first distribute the angular error before commencing computations. The error in latitude and departure is distributed only on the longest courses.

The D. M. D.'s and latitudes need not be closer than tenths in multiplying for areas, which in turn need only be recorded to single square feet. Results will then be reliable to 0.001 acre.

It is quicker to multiply for areas than to interpolate with logarithms. Areas can be *checked* graphically by subdividing the plot into triangles and scaling the bases and altitudes, with results generally accurate to 1 in 300.

When the area is known, in square feet, a rough check on the acreage may be found by pointing off six places and multiplying by 23, which is nearly the reciprocal of 43,560.

*[illegible], N. Y.

Portable Concreting Plant with Telescopic Tower

In building the concrete bridges and the railway floors in the grade-crossing elimination work at Tower Grove, St. Louis, Mo., two different methods were employed for placing the concrete. For the portion over the St. Louis & San Francisco Ry. (done by contract), a portable plant with mixer and short telescopic elevator tower was employed, while for the portion over the Missouri Pacific Ry. (done by company forces) the plant was stationary and had the usual tall tower and long chutes.

The portable plant, shown in the accompanying cut, was very inexpensive, and was readily moved from place to place as the work progressed. It consisted of a $1\frac{1}{3}$-yd. mixer with a small steam engine and boiler, mounted on a self-propelling four-wheel frame or truck. The elevator tower was mounted on a pair of sills, having the end supported by and bolted to the mixer frame, while the rear end was carried by a pair of wheels.

The usual cable for hoisting the charging skip of the mixer was disconnected from the drum, and a right-angled hook was spliced upon its end. A hole was bored in the face of the drum to engage this hook. A similar hook was attached to the bucket-hoisting cable. This arrangement permitted the use of the same drum for hoisting the charging skip and the concrete bucket, the one being removed while the other was in operation. This was done by a man stationed at the drum for this purpose.

Portable Concrete Mixing and Delivering Plant with Telescopic Elevator Tower

The tower was $4\frac{1}{2} \times 4\frac{1}{2}$ ft. in plan in the lower section, which was 3[illegible] ft. high. The upper section was slightly larger than the lower half and could telescope over the latter, so that a minimum height of [illegible] ft. could be obtained, for passing under electric wires. This upper section was 18 ft. high, and the maximum height of tower was 54 ft. The tower was raised and lowered by the hoisting cable and a set of blocks.

A tilting elevator bucket was used, and at the top of its travel it discharged the concrete into a hopper attached to the tower. From the bottom of this hopper extended a chute 35 ft. long, which was suspended by stays from a boom at the head of the tower.

This portable concreting plant with telescopic tower was designed jointly by Percy [illegible], Assistant Engineer, St. Louis & San Francisco Ry. (who is in charge of the grade-crossing elimination work at Tower Grove),

and G. D. Weeks, Superintendent for the Jarrett-Richardson Co., which has the contract for this work.

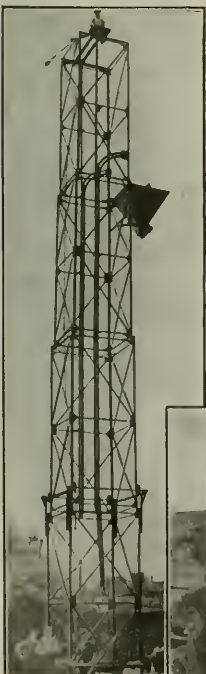
When the nature of the work in progress does not require the tower, it is uncoupled, the charging skip is rigged to the drum and the mixer is then available for concreting the street foundations, sidewalks, etc.

The capacity of this plant was about ⅓ cu.yd. of concrete at a batch and 1½ minutes was required for each batch. The highest record of work done by the plant was 90 cu.yd. in 10 hr. This plant was very satisfactory for the work, which consisted of retaining walls with a maximum height of 14 ft., having expansion joints 35 ft. apart, the wall being built in alternate sections. These walls were situated on three different streets, along which ran numerous electric wires and on two of which ran street cars. The tower was moved twice in the length of the walls, and the work was done without interrupting the street traffic.

Fire-Pail with Foil Cover—An improved metal fire-pail covered with foil to prevent evaporation and the accumulation of rubbish, is made by the Eureka Chemical Fire-Pail Co., Philadelphia, Penn. The pail is refillable. The foil, which is easily broken by the hand, is protected by a metal lid normally. The pail is enameled.

A Sectional Telescoping Hoist-Tower

A sectional telescoping hoist-tower is a novelty brought out by the Lorentz Iron & Machine Works, 95 Liberty St., New York. The two views herewith show such a tower in position, set up and when telescoped and loaded on a wagon. The tower is built in 15-ft. sections, telescoping successively, framed of steel angles. The lowest section is provided with winding shafts, worm-geared, by means of which the several sections are raised to extended position. Important features of advantage are the speed of setting up and taking down the tower, and the absence of damage or deterioration in taking down and reërecting.



Telescopic Concreting Tower

Testing a Testing Machine; Simple Method

By Julian C. Smallwood*

For calibrating vertical testing machines of the Olsen or Riehlé type, the makers recommend the use of "proving levers" such as are illustrated by Fig. 1. Arranged as shown, the force produced by weights suspended from

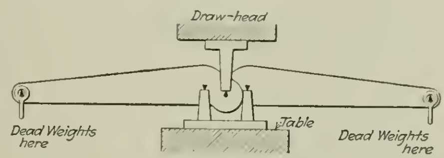


FIG. 1

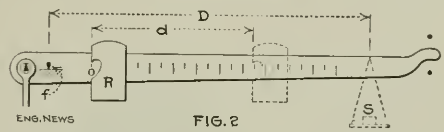

FIG. 2

Fig. 1. Proving Levers on a Testing Machine

Fig. 2. Weighing Beam with Auxiliary Scale Pan in Place

the ends of these levers will be multiplied by the ratio of lever arms, 10, and transmitted to the table of the testing machine. The multiplied force may then be measured on the testing-machine beam, and the machine calibrated. It is customary to test the machine in this manner up to one-tenth its capacity. It should be noted that the calibration, being static, does not duplicate the actual conditions of use, namely, the balancing and measuring of moving forces.

It was sought by the writer to prove a 200,000-lb. machine used in the laboratory of Syracuse University. The method outlined above was objected to because it involved the handling of 2000 lb. of dead weights. Consequently another method was devised, the theory of which is as follows:

The New Method

The weighing beam of the machine, Fig. 2, is fulcrumed at f and carries the rider R which may be adjusted at a distance from the fulcrum such as to balance any load applied to the testing-machine table. With no load, the rider is in the position shown, its pointer being at the zero graduation and its beam floating. With a load W on the table, the rider must be moved through a distance d to secure balance. If the machine is correct, the weight of the rider must be such that the distance d will be that between the zero and the graduation marked W. Now, instead of using the rider, another weight could be applied at any convenient part of the beam as shown by S, of such amount as to secure a balance when the load W is on the table. Therefore, the moment of the weight

*Associate Professor, Experimental Engineering, Syracuse University.

S about the fulcrum F must equal the moment of the rider which is replaced. Letting R denote the weight of the rider,

$$S \times D = R \times d$$

Let the ratio of the load on the table to the balancing weight S be L. Then

$$S = \frac{W}{L}$$

Substituting this in the first equation, and simplifying, we find the weight which the rider must have in order to suit the existing graduation of the beam:

$$R = \frac{D}{d} \times \frac{W}{L}$$

To apply this relation to the calibration, a value of W is chosen, and the distance between the beam graduation marked W and the zero graduation is carefully measured. This determines W and d. A point is then chosen to represent D, and its distance measured from the fulcrum F. To find the ratio L, it is not necessary to apply the full weight W to the table, since the ratio $W \div S$ is constant for all values of W, the ratio of levers being established by the selection of D. Therefore the following procedure is used. An appreciable, but not inconvenient, number of weights is placed on the table, these having been previously measured with a platform scales to within 1 lb. They may consist of anything available that can be readily moved. A balance pan, improvised from pasteboard and wire, is then attached to the beam at the distance D from the fulcrum, and to this pan are added shot or other small weights until a balance is secured. If desired, the weight of the pan may be previously balanced by the usual beam counterweight so that the experimenter need deal with the added weight only. The latter should then be accurately weighed to a fraction of an ounce. This result, divided into the weight applied to the table, gives the desired ratio L. The value thus obtained completes the data necessary to calculate the weight of the rider according to the equation previously deduced. The rider is then removed from the beam and weighed. If the actual checks the calculated weight, the machine is proved at the graduation marked W. Any other graduation may then be checked by proportion, since the distances of the graduations from the zero mark must vary directly with the indicated loads.

Test of a 100-Ton Machine

Following are the data and results from the test of the previously mentioned 200,000-lb. machine:

Beam carried two tandem riders to balance increments of 100,000 lb. each; W was chosen at 100,000 lb. so as to make the error in measuring d as small a percentage as possible; d = [illegible] in.; D = [illegible] in. To find L, a dead weight was placed on the table equal to [illegible] lb. Balancing weight, acting at D, rider being at zero, was [illegible] lb. Hence

$$L = [illegible] \div [illegible] = [illegible]$$

Then the rider should weigh

$$R = \frac{100,000}{[illegible]} \times \frac{[illegible]}{[illegible]} = [illegible] \text{ lb.}$$

The actual weights of the riders were found to be [illegible] lb. and [illegible] lb. The lever system of the machine was thus proved to about [illegible]% of error.

When determining L, it is well to make several trials involving different loads on the table, for checks. It is also important that the error brought about by lack of sensitiveness of the beam be estimated. This may be done after a balance has been secured, by noting what weight of shot may be added to or subtracted from the improvised pan to appreciably disturb the balance. The proportion that this bears to the whole weight of shot gives the proportion of error in the determination of L, since the load on the table is found with comparative exactness.

Sources of Error in Testing Machines

It is believed that this method of calibration is quite as reliable as the proving levers, besides having the merit of convenience; but, on the other hand, it seems that any static calibration should be supplemented by further examination. The question arises, at what points in a geared testing machine may sources of inaccuracy be looked for. One would not expect ordinary service to alter the arrangement of the levers, and, if this is the case, the beam would be expected to retain its accuracy, if the riders are not tampered with. Abuse of the machine might conceivably set the links connecting the levers or the knife-edges awry, which might make the balance sluggish without materially affecting the lever ratio. Grit from stone or concrete samples, if allowed to collect around the knife-edges, would have this result, as would the rounding or flattening of the knife-edges. In regular operation, sluggishness of the lever system would result in the rider being always behind its true position.

The rider is commonly advanced along the beam by means of a screw actuated by a handwheel set in the frame. The reaction on the beam caused by the force transmitted through the screw causes a slight lifting effort on the beam. If the rider does not work freely on its screw, this lifting effort may be considerably increased so that, in operation, the rider will be materially in advance of its true position in order to balance the lifting effort.

From these considerations it will be seen that the static calibration of a testing machine should be supplemented by an examination of all its knife-edges, and that the handwheel controlling the rider should be tried for its frictional resistance. Further, it should be ascertained that the table is free from the power screws, and from the guide bolts passing through it. Finally, a test for sensitiveness may be made as follows:

Test for Sensitiveness

A large rigid metal piece of any convenient shape is placed on the table as for regular compression test. A moderate load is applied, say [illegible] to [illegible] lb., the beam balanced by advancing the rider, and the reading recorded. The rider is now further advanced by a few inches, then returned until the beam again balances, and a second reading taken. If this is less than the first, the difference may be due to the reversal of frictional resistance of the screw, the lifting effort being changed to a depressing one. If greater, it may be due to sluggishness of the lever system. If the two readings depart more than 1 or 2% from their average, the cause of the error should be sought. This experiment should be repeated at several loads, care being taken not to exceed the elastic limit of the material under compression.

Unit Steel Forms for Concrete Floors and Walls

The accompanying view, Fig. 2, shows the wall forms used by Collins Bros., contractors, in the construction of the reinforced-concrete building for Henry Dart's Sons Co., at Rock Island, Ill. These forms, which are used in the building for both wall and floor-slabs, are of special unit type devised by the Blaw Steel Construction Co., Pittsburgh, Penn. The diagram in Fig. 1 shows the sheeting in detail.

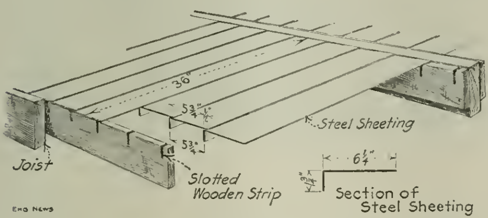

FIG. 1. DETAILS OF BLAW STEEL SHEETING FOR CONCRETE WALL AND SLAB FORMS

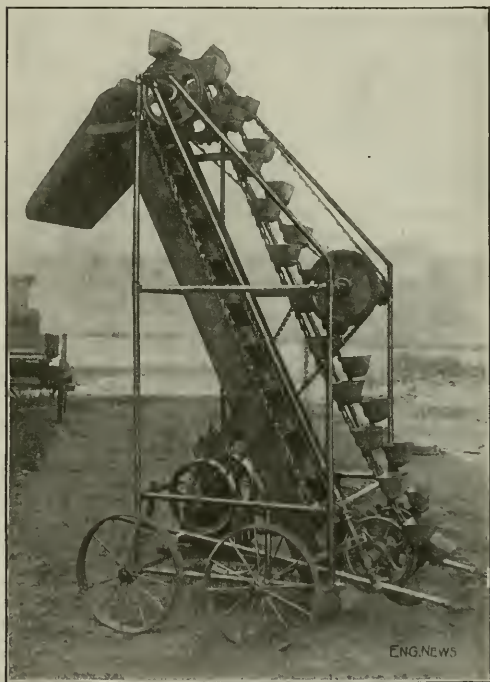
Each unit consists of an L-shaped section of light pressed steel, 36 in. long and 6¼ in. on the long side and 1¾ in. on the short side of the L. This 36-in. length spans the joists of the falsework in a floor or the studding in a wall form, the short leg of the L fitting into saw kerfs spaced 5¾ in. apart on light studding nailed to the main joist, as shown in the upper part of Fig. 1. This spacing allows a ½-in. overlap of the long leg of each unit on the next unit and the continuous line thus presents a tight surface for the concrete of slab or wall, broken only by the evenly spaced ridges at the overlap.

FIG. 2. WALL OF DART BUILDING, ROCK ISLAND, ILL., SHOWING UNIT FORMS IN PLACE

At the end of a few days, when the concrete has taken an initial set, the supporting studding may be taken down and the sheathing made ready for use again; meanwhile the slab or wall is supported at 36-in. intervals by the joist or stud which is left in place for the three or four weeks required before the entire removal of forms.

A Light Portable Wagon Loader

The use of mechanical wagon loaders in place of hand shoveling, for placing gravel, stone, sand, coal, ashes, etc., on wagons or motor trucks, is becoming very general, on account of the large saving in cost over hand shoveling. In the machine of this sort here illustrated, the effort of the designer has been to cut down the weight to facilitate the easy removal of the machine from one place to another. As seen in the illustration, a light steel pipe frame is used, and the weight of the entire machine has been cut down to a thousand pounds. Ball bearings have been introduced into the principal working parts, thus reducing the friction so that a little gasoline engine of only 1 hp. is sufficient to drive it; thus, the power equipment adds but little weight to the loader.



A LIGHT PORTABLE WAGON LOADER

In order to further facilitate the movement of the machine, its weight is balanced about the main pair of wheels, so that by pressing down on the projecting handles one man can balance it on these wheels and readily turn it. After the machine is set in place, ready for work, the handles can be pushed back out of the way. This machine, which is called the Jersey Wagon Loader, is manufactured by the Lorentz Iron & Machine Works, of Jersey City, N. J.

A New Dipper Handle for Dredges and steam shovels is composed of two steel channels placed with their flanges inward and welded together, so that they form a single member of rectangular box section. The design is patented and is being introduced by the American Steel Dredge Co., of Fort Wayne, Ind.

NOTES

A Good Record for an Old Dredge is reported in the "[illegible] Record" of Sept. 16. The French ladder dredge "Rad-[illegible]," which was built in Belgium in 1886, has just been condemned on account of defects in its hull. The dredge was operated at [illegible] for the French company organized after the [illegible] collapse and was beached when the work was suspended. It lay unused until [illegible] when it was repaired and put in service, about $[illegible],000 being expended in the work. Since that time it has been operated almost continuously. The fact that the iron hull and the machinery of this vessel have withstood the tropical climate of the Isthmus for twenty-eight years is noteworthy. The dredge had buckets of [illegible] cu.ft. capacity and was capable of excavation to a depth of [illegible] ft.

Plaster-Board Forms and Ceiling for Ribbed Concrete Floors—A new type of ribbed-floor construction in reinforced-concrete employs inverted troughs of gypsum plaster-board as permanent forms for the ribs and slab, with flat plates of the same material for the ceiling. This material (Sackett plaster-board) is pressed to shape for the troughs, and before setting these in place the ceiling plates are attached to the flanges by means of metal clips. The construction is shown in Fig. 1, and Fig. 2 shows the troughs nested for transportation.

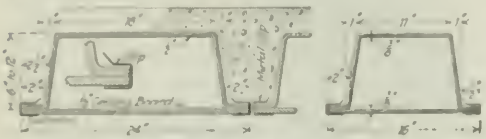


FIG. 1. RIBBED CONCRETE FLOOR CONSTRUCTION, USING FORMS AND CEILINGS OF GYPSUM PLASTER-BOARD

The troughs are made of different sections, in 36-in. lengths, and can be sawed to any required length. Their ends are closed by flat plates. The plaster board is treated with a waterproofing composition, so that it will not be liable to injury by the weather during transportation or on the work. The material adds very little to the weight of the floor, the weight being only about 3½ lb. per sq.ft. for troughs 24 in. wide and 10 in. deep, with ceiling board in place.

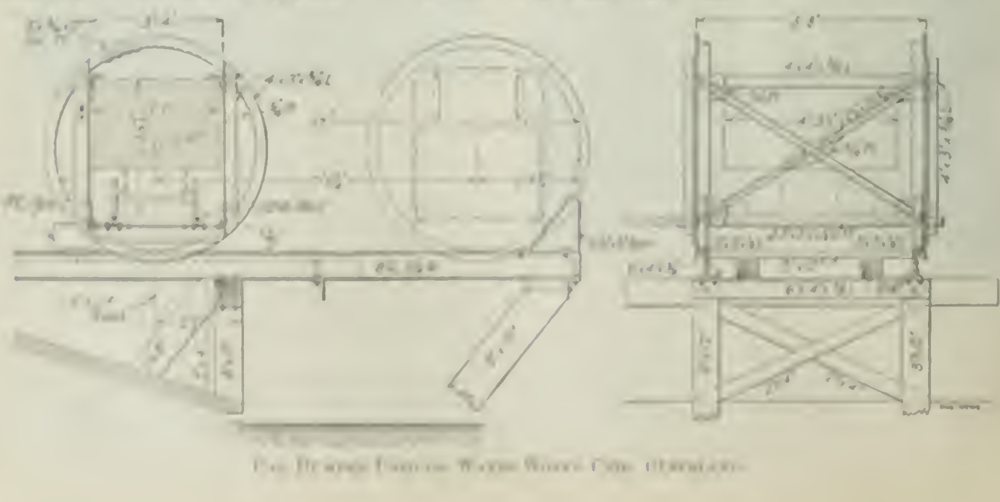
The plastering for the ceiling is stated to cost 25 to 40% less with this construction than with steel lath. The plaster-board form is rigid and will not sag or bulge. The extra fire protection of the surface of the concrete ribs by ½ to 1 in. of plaster-board is claimed as a further advantage.

This system of floor construction has been adopted for the Y. M. C. A. Building now under construction at Streator, Ill. This is a three-story building of reinforced concrete, about [illegible] ft., with spans of 17, 18 and 24 ft. The loads

FIG. 2. FORMS OF PLASTER-BOARD FOR RIBBED CONCRETE FLOORS

are 150 lb. per sq.ft. for the first floor and 6[illegible] lb. for the upper floors. The troughs are 24 ft. wide over the flanges, with a depth of 6, 8 and 10 in. for the three lengths of span noted. The material is supplied by the United States Gypsum Co., of Chicago. The contractor is H. Tappendorf, of Streator. The architects for the building are Foster & McLane, of Streator.

An Improvised Car Dumper, designed by S. E. R[illegible], Assistant Engineer, Cleveland Water Department, and built under his direction, has been in use at the water-works intake at Cleveland in the disposal of the excavation from the tunnel and of the débris from cleaning out of an old tunnel which leads into one of the cribs. In the accompanying figure details of the dumping device are shown. On the crib into which the tunnel leads there is erected a cantilever frame carrying two 8-in. channels out over the lake. On these channels as rails a [illegible] steel framework rolls from a fixed bumper, made of 8-in. channels riveted to the top of the rail channels above the crib, to an outside bumper made of [illegible] in. bars bent up at the extreme end of the cantilever frame. When at its inside position the [illegible] frame carries at its bottom section a narrow-gage track, which is continuous with a track leading out from the elevator in the crib. A small narrow-gage dump car is filled from the elevator and run out over the track into the [illegible] frame. The frame is then given a push by laborers and rolled out by a slight down grade of the cantilever, the car automatically overturning and being held from falling out by brackets [illegible] riveted to uprights shown in the cut. When the car load is thus dumped overboard, the empty car in the frame is pulled back into its place.



CAR DUMPER USED ON WATER-WORKS CRIB, CLEVELAND

The Market for Municipal Bonds

In the three months since the declaration of war in Europe, from Aug. 1 to Oct. 31, the sales of municipal bonds in the United States fell off about \$50,000,000, according to statistics collected by the *Bond Buyer*. The total sales of municipal bonds during these three months were \$31,311,000, whereas in the same three months in 1913, \$79,790,000 was marketed. In the three months preceding the outbreak of the war over \$100,000,000 of such securities were sold.

There are signs, however, indicating that the coming month may see a revival in the demand for municipal bonds. A large proportion of the sales of such bonds are to savings banks and life-insurance companies, and there is little doubt that during the closure of the stock and bond markets since the war began, money has been accumulating to a considerable extent which is available for investment. There has been, in fact, a very marked improvement in the general tone of the Wall Street money market.

Two influences which have withheld investors from purchasing have been the feeling that with the opening of the financial markets again it would be possible to obtain exceptional bargains in investments, and the feeling that with the uncertainties of the world situation, it was a safe plan to keep a considerable supply of money available for instant use. Both these conditions are passing, and as soon as the bond market is fairly in operation, a considerable increase in the sales of municipal bonds may reasonably be expected. If this prediction is realized, it will be most gratifying to the cities who are holding back important public works until they can secure capital, and to engineers and contractors whose employment depends upon such financing.

Commission Government for Buffalo

The City of Buffalo at the election last week voted to adopt the commission form of government, and will be the largest city in the United States to try this plan of administering its municipal affairs. As our readers will recall, Engineering News has at no time maintained that the commission plan was an ideally perfect form of municipal government; and as most intelligent men realize, no plan of government for a city, or a state or nation can be successful, save as it is administered by men of ability and honesty.

It remains true, nevertheless, as every engineer, at least, will agree, that the old plan of city government with its multiplication of officers is cumbrous and inefficient compared with the commission plan and its concentrated responsibility.

That old plan of city government, which is still in use in many cities, where the mayor is the executive head with two different legislative bodies to act as a check upon each other, was intended to be a copy of the scheme of government in use in the several states. One main defect of a government of this sort is that it is far better adapted to prevent things being done than it is to do things. A century ago, when the old aphorism that that government was best which governs least was widely accepted, the attainment of efficiency in a municipal or a state government was not necessarily a matter of vital importance.

The governments of the present day, however, are doing many things which were undreamed of a century ago and the tendency all the time is to increase the work undertaken directly by the municipal government. Under these conditions it makes a vital difference to the taxpayer and the citizen whether efficiency or inefficiency prevails in the government of his city. The mere fact that the commission form of government is more efficient by far than the old mayor, aldermen and council plan makes the change in Buffalo one upon which its citizens are to be congratulated.

One-Sided Engineering Contracts

Something is radically wrong with either engineers or lawyers when a lawyer* is led to write as follows:

> The entire trouble is with the present-day construction contracts and their specifications or at least the general conditions of the specifications. In discussing the present-day railroad construction, the following has been stated: "It is safe to say that in no other business relations between men are such one-sided agreements customary; in no other relation is a man conceived to be clothed, by reason of an instrument, in a mantle of infallibility, as is the engineer in customary railroad contracts." The same is true of all United States, state and all municipal contracts, and even of many private contracts. From personal knowledge of contracts of the City of New York and the interpretations by the Corporation Counsel and some of the engineers, I am of the opinion that in signing such a contract the contractor, architect, or engineer gambles worse than on the stock market. He frequently becomes an insurer and an exponent of faith, hope and charity.

A contract is supposed to be a fair bargain. In all the decisions and discussions of engineers, fairness is always assumed to be the keynote of the relations between the engineer and contractor; but by the above quotation and by very general experience as well, many (if not most) contracts are so far from fair that it would be undeserved praise to even call them unfair.

A mere ethical protest against such a condition might be commendable; but it would have little chance of success. If engineers can write such contracts and enforce them, they will doubtless continue to do so, notwithstanding all ethical protests. But when courts of law decline to recognize such contracts, and insist on interpreting them in the courts' own way, on a basis of fairness, regardless of the specific terms of the contract, then engineers are bound to stop and give the matter thought.

*Wm. L. Bowman, in a recent address before the Harvard Society of New York, "The Engineer and the Law."

How long will engineers continue to write contracts and specifications that are not only grossly unfair, but are without legal force?

The Yale Bowl

The novelty of the structure erected at Yale as a football amphitheater lies not only in its popular aspects, but just as much in its construction and design. Gathering 61,000 people in a walled camp, which can be entered and left only through tunnels, is rather radically new. There is every reason to believe that the innovation will be fully justified by the success of its first trial—at the Harvard-Yale football game on Nov. 21.

To build a concrete grand-stand on a freshly placed earth embankment is almost as novel as the general idea of digging out an amphitheater below ground-level in order to furnish material for the embankment—an operation which called for the adoption of very special methods of excavation in order to handle the job cheaply and expeditiously. Of course, the problem was to secure a dense and firm embankment on which the seats could be built without settlement, and there was some difference of opinion, we understand, as to how this problem ought to be handled.

The original project contemplated making the embankment a simple dump, without much or any attempt at consolidation; the material was to be deposited in thick layers and not rolled. The contract and specifications were actually drawn on this basis. Later, when the contract had progressed some distance, after the tunnels through the bank and the first few feet of bank had already been constructed, the engineers in charge modified their views, and came to believe that the embankment should be made fairly firm and solid from the start. The contract was thereupon altered to call for what amounts to reservoir-embankment construction, depositing the material in thin layers and rolling it thoroughly.

Of some interest in the same connection is the fact that it was originally planned to build the concrete seating structure all the way up the slope, on the fill as well as on the part in cut, and thus with unconsolidated fill as originally contracted for. The later decision to put a temporary wooden seat-deck on the embankment, and restrict the concrete seating for the present to the portion which is in cut, will certainly be regarded as wise.

The [illegible] structure, unfortunately, will be very [illegible]. [illegible] it is to be used for the college football games only. It means that only in the fall, and then for not more than possibly half a dozen afternoons, will it be in service. The field is too small for baseball, and the whole structure [illegible] regarded as unsuitable for track and field sports, for which another stand on another field will be provided. On account of its large seating capacity the bowl [illegible] pay [illegible] in [illegible] under the circumstances.

Original Cost vs. Replacement in Railway Valuation

In commenting [illegible] [illegible] the Federal Railway Valuation Act at the time it was passed, we criticized the clause in the act which requires the valuing engineers to determine not merely the cost of replacing the line at the present time, but also what was the original cost of construction, together with the amounts which have been expended since on improvements. We suggested that this clause in the law would require a search into past history, requiring a vast amount of labor, and that many of the facts necessary to complete the records could never be ascertained.

An interesting illustration of how this task of searching past history works out in practice is furnished by a circular issued by the Valuation Committee of the Central Railroad of New Jersey, of which Charles Hansel is the Chairman. The circular states that representatives of the railway company who will accompany the Federal Valuation Engineers, will point out to them certain obscure items which materially increase the cost of the completed work, and which are not apparent in a field inspection. Mr. Hansel makes the following list of some of the items which may have caused a large increase in the cost of original construction, and yet be not at all apparent now.

Sunken embankments, old excavations filled up, trestles and other structures which have been filled with earth embankment, sink holes, cuts which were wet during construction and therefore caused extraordinary costs, but which are now dried out, disintegrated or earth-covered rock cuts, which might now be classified as earth at a low price when compared to the original cost of rock excavation, temporary roads, trestles, tracks, embankments, [illegible] and other structures required during construction, traces of which have disappeared, excessively costly foundations of bridges, [illegible] and other structures, unexpected drains and culverts, conduits, sewers, [illegible], water pipes, [illegible], dams, [illegible], retaining walls, flumes, [illegible], rip-rap, mattresses, etc., not readily discovered, and especially those which are outside of the right-of-way, roads, channels and streams which have been diverted, the knowledge of which cannot be had from mere inspection, [illegible] which were originally [illegible], but which have settled below the subgrade; items incident to eliminating grade crossings, [illegible], or [illegible] trains, particularly [illegible] traffic, and similar extraordinary construction items; [illegible] paid contractors for delay in furnishing material or facilities; extra cost of work owing to extraordinary weather and other conditions, strikes, etc., or on account of [illegible] and other [illegible] of the construction [illegible], [illegible] drainage, etc., of streets, and [illegible] of the construction, [illegible], drainage, etc., of streets, and other improvements of various kinds off the right-of-way, paid for wholly or in part by the railroad companies; [illegible] agreements [illegible] against the railroad companies for [illegible] [illegible], etc.

Mr. Hansel declares that in many cases the only way to determine the facts in the relation to many of the items above cited will be through the personal recollection of those who were connected with the original construction work. He is therefore sending this circular to every present employee of the company and to all former employees, as far as they can be located, especially in the engineering department. He appeals in the circular for old field books, maps, profiles and plans, and for the addresses of retired officers and employees, or of contractors who may have done work for the road formerly.

From the railway company's point of view, it is, of course, desirable to present these matters to the Federal Valuation Engineers to enable them to form a fair estimate of what it would cost to replace the road at the present time, as well as the estimate which the law requires of the original cost of construction. The very fact, however, that a knowledge of these items depends [illegible] on personal recollection makes it clearly evident how futile is the task of trying to obtain a complete history of construction and betterment expenditures on railways built a half century or more ago, as were a large

part of the lines comprising the Central Railway of New Jersey system.

How few of the engineers and contractors, who were in responsible charge of work even 30 years ago, are still living and able to furnish authentic information. Even when such men can be found, their recollection of events occurring so long ago, must of necessity be more or less vague and hazy, and will be an uncertain foundation on which to base a dollars-and-cents estimate of cost.

There is, however, another and still more important aspect of this search into past history. The ultimate purpose of the valuation is doubtless to furnish an authoritative basis for fixing railway rates.

Now a very little study and in fact the common sense of the individual indicates that a railway is entitled to earn a fair income on what its property is worth today, not on what it may have originally cost. This is merely applying to railways the rule which applies to all other lines of business and industry. It is the universal rule that the income from a property—be it a farm, a factory, a mine, a house or a going business—depends on what it will now earn in net income, not at all on what it may have originally cost the owner. Of course, railway rates cannot be based on a valuation governed by net earnings, since the rates themselves determine the earnings, but they can fairly be based on what the railway's entire property as it stands today as a going business could be reproduced for under present conditions, since this is the condition under which other industries are carried on.

A manufacturer, for example, buys a complicated and expensive labor-saving machine as soon as it appears on the market. He thereby gains such an advantage over his competitors that for a year or two he is able to make very large profits. At the end of that time, the machines are produced in such large quantities that his competitors can buy them at a comparatively low figure. He must meet their competition, based on low-cost machinery, and reduce the prices of his goods to compare with their quotations, regardless of the prices he may have paid for his own machines.

If an inventory of his plant were made, the machines would be appraised at what they could be replaced for, no matter what fancy price may have been paid for them originally. Similarly, the owner of a piece of real estate can obtain a rental for it based on its present selling value. This value may be several times as much as he originally paid for it, or on the other hand, it may be very much less.

So a railway company may, in the early years of its history, have spent a vast amount of money in excavating a hard rock tunnel with hand drills and black powder. It is entitled today to earn interest only on what the tunnel could be built for with modern machinery and dynamite. On the other hand, it may have done a large amount of work in its original construction with very low-priced labor or with convicts, whereas today the restrictions of the labor unions or other economic conditions would make the reproduction of the same work twice as costly. The true valuation of its property is the valuation at which it could be replaced under present-day conditions.

So with the real estate that the railway company owns and uses in its transportation business. This may have been secured originally for a nominal consideration, or even given outright by a municipality for use as terminals. The railway is nevertheless entitled to earn an income today on the present value of this real estate, based on what it would cost at present to acquire it. Of course the rule works both ways. Some of the real estate now held by the railways, owing to business and residential changes, is worth less than its original cost.

The economic basis for this rule with reference to valuation lies in the fact that it applies to the public utility corporations the same rule that is applicable to all other industries in which free competition prevails. If it were indeed possible to have free competition in the operation of public utilities, then at any time when a railway charged exorbitant rates a competitor could build a line alongside and could base its rates on the cost of its new construction, which would compel the reduction of rates on the old line to that standard, no matter how much more costly the old line was to build. The rule, therefore, simply aims to compel, by process of law, what would take place through the natural force of competition, were the business one in which competition could prevail.

We are aware that there are strong influences in favor of the other plan of valuation, by ascertaining what the company has actually expended in the creation of its property and upon improvements thereto and taking this sum less depreciation as the value of the plant on which it should be permitted to earn an income.

Were it possible to ascertain these historic facts with anything like accuracy, and if the company had been under public control as to rates, service and expenditures from its establishment, much might be said in defense of this plan. But these conditions obtain in few cases. Many railways were originally built by construction companies, which were organized for the express purpose of making a large profit on the difference in the price paid by the railway company and that received by the actual contractor. A part of this profit may even be legitimate as a part of the necessary promotion expense in bringing the railway into being; but it is not to be believed that the public will stand for rates which make the profits reaped by dead financiers a generation ago a part of the permanent capitalization on which rates are to be based.

The influences which carried the Federal Valuation act through Congress, in fact, bitterly opposed this very thing. The idea that the present railway capitalization represented in large part "dead capital" and not present values, was the impelling motive in bringing about the passage of the act. If therefore, the historic basis should be used for railway valuation instead of the replacement basis, there is danger that the whole work may lose its authoritative character and that the public may refuse to accept it as fair.

We freely admit that the unearthing of past records, showing difficulties and extraordinary expenses in connection with the work, may have a certain value in making the Federal Valuation Engineers give fair allowance in their estimate of replacement value for those extraordinary items in connection with construction, which so often play a large part in increasing the final cost over the original estimate. But to attempt to make a complete valuation on the historic basis is attempting the impossible in most cases and even if it were fully determined, the public would discard it as unfair.

Letters to the Editor

Experience with Concrete-Pile Foundations in the Detroit Clay

Sir—The article on "Foundation Design, Michigan Central Railroad Terminal," in your Oct. 1 issue, has been construed by some to mean that no concrete piles were found which could safely be expected to carry a load of 30 tons each. This was not the conclusion drawn by the Michigan Central R.R. as is evident when it is known that on a portion of this terminal Raymond concrete piles were used on the recommendation of G. H. Webb, Chief Engineer, under the above mentioned loading.

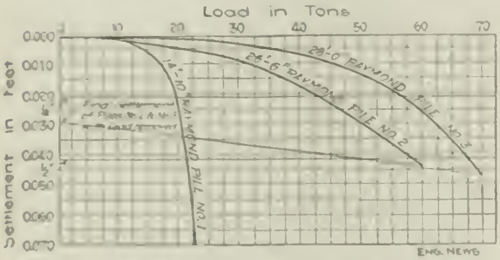

Fig. 1. Load-Settlement Curves for Three Raymond Piles in Tests for Michigan Central Terminal Foundation

Pile 1 was short, being driven through hard-baked crust on surface, but was tested after hard rain. Piles 2 and 3 were driven in pits excavated through surface crust. The final load per square foot of friction surface was nearly the same for the three piles.

Pile	Friction Area, Sq. Ft.	Final Load, Lb. per Sq. Ft. Friction Area
1	3? 50	1064
2	93 50	1130
3	1?? 25	12?0

While some types of concrete piles seemed unadapted to the local soil conditions, the curves in Fig. 1 herewith will show that 30 or even 40 tons could be safely placed on the tapered piles tested, provided, of course, that they were driven to a reasonable depth, which in this locality was from 20 to 30 ft.

Pile 1 was driven under unusual conditions in that the surface of the ground consisted of hard-baked crust caused by an extreme drought which occurred just previous to this time. Piles 2 and 3 were driven in shallow excavations which penetrated this crust. Between the time of driving Pile 1 and the placing of the test load, the crust was thoroughly soaked and softened by abundant rain, so that the conditions when the load was applied were similar to those under which the two other piles were driven, after the upper crust had been removed. This short pile is therefore interesting, not for the total load carried, but for the relative load, i.e., the load carried per square foot of lateral surface. This, as shown below the table of curves, is remarkably close to the frictional value of the two longer piles.

The cost of placing concrete piles, however, together with the fact that there was some doubt as to whether the piles could be driven to a sufficient depth in the large piers required, on account of the extraordinary nonconpressibility of the soil, made the adoption of the mat foundation economical, as stated in your article.

The only gray clay under the Michigan Central Terminal is much more dense than the general soil of the Detroit district. The geological formation is very similar, however, to that found for a considerable distance from this point along the shores of the Great Lakes. Fig. 2 shows the character of this soil, which is so tough that it has to be actually cut out, and handled with a fork (shown in the photograph). The holes in the clay made by the fork can be clearly seen even though the clay has been exposed to a hard rain for several days. In time, however, this material will "weather" and run into a solid mass again. The material under the downtown district of Detroit is much softer and is considered on the whole much less trustworthy for building purposes. In the last few years over 60,000 ft. of Raymond concrete piles have been driven in Detroit, under 12 buildings. None of these piles is loaded less than 20 tons and the majority carry 30 tons. In some cases the calculations have shown that the actual load on the piles after the building had been erected and filled was 35 tons, but in no case has any appreciable settlement been evident or the slightest difficulty experienced with the foundations. Engineers therefore feel justified in using 30 tons as a safe load to allow on tapered Raymond piles.

Fig. 2. Slices of Clay Subsoil Excavated at Michigan Central Terminal Site

(Were excavated by hawk-bill and handled with fork (fork shown in view). The pile was exposed to several days' rain before the picture was taken, but the slices still show the fork holes.)

In 1909, the Bohl Mfg. Co., of Detroit, built their five-story warehouse on Raymond concrete piles, loading them to 30 tons each. Even though these loads have been increased over what was originally contemplated, no settlement has been found. This was the first building in Detroit to be built on concrete piles. Since then, Ray-

mond concrete piles have, been used under the following buildings:

Date	Name	Loading, Tons per Pile
Dec., 1910	Buhl Malleable Co.	25
May, 1911	Boyer Campbell Warehouse	30
July, 1911	Free Press office building, first half	30
Aug., 1911	Kiefer Building, office and store building	30
Aug., 1911	Murphy Iron Works, office building	25
Mar., 1912	Free Press office building, second half	30
Apr., 1912	Murphy Iron Works, factory	25
July, 1912	Central Heating Co., power plant	30
Jan., 1913	Standart Bros. warehouse	20-30
Jan., 1912	Dodge Bros. warehouse	30
Sept., 1913	Michigan Central R.R. Co. station	20

Flat Slab Indulgences

Sir: In your issue of Sept. 24, 1914, p. 632, there appears the new Chicago building code as applied to flat slabs. Some uncertainties in the ruling for the four-way system should be pointed out:

Strip A (a strip crossing the columns and of a width equal to one-half the panel length) is said to have a negative moment "at the edge of the column cap or over it" with a coefficient $^1/_{15}$. Is the designer permitted to make his own selection as to the location of this bending moment and if he selects "over it," is he permitted to consider the column shaft as part of his resisting section—an inverted T-beam of any depth desired?

Another feature of the code is the entire absence of any provision in columns for the tremendous bending moments that they must take unless the load happens to be balanced. It is true that the code says: "Special attention shall be given to the design of the column capital in considering eccentric loads;" but how on earth can a column capital have eccentric loads without the same being taken by the column shaft?

How any designer can compute tremendous bending moments in column capitals and then totally ignore these in his column shaft is a mystery. And yet this is the common way to design a flat-slab system, and it is sanctioned by this code. The proof that this code allows a bending moment, *even in wall columns,* is found by comparing the moment coefficient for wall panels supported by columns and girders and that for panels on brick walls. Another proof is in the placing of the point of inflection one-quarter of the distance center to center of columns.

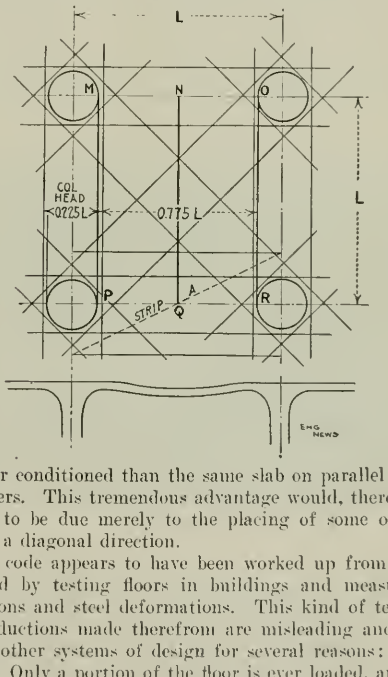
The bending moment in Strip A is found to be $^1/_{80}\ wL^3$ at middle span, where w = total load per sq.ft. on the slab. (The coefficient $^1/_{80}$ is brought in by using w as the load per sq.ft. in place of using W as the load per lineal foot on a strip $\frac{1}{2}\ L$ in width.) Now in the rectangle $MPRO$ (see accompanying cut) we have a slab which, for purposes of discussion, we may consider supported along PM and RO. In the section NQ of this slab there are three complete bands of rods, but since two of these are at 45°, they will be equivalent, if fully stressed, to 1.41 bands. Hence the full resisting value of the bands of rods, assuming all bands alike, is 2.41 times that of one band, in the section NA, or $2.41 \times {}^1/_{80}\ wL^3 = 0.03\ wL^3$.

In the slab $MPRO$, the bending moment at NQ plus that at MP or OR must, by the theory of flexure, be equal to the product of the load on the span and one-eighth of the span length, or $w \times 0.775\ L \times L \times \frac{1}{8}\ L \times 0.775 = 0.075\ wL^3$. The minimum value of the moment either at MP or NQ is then one-half of this, or $0.0375\ wL^3$. In each of these sections named, there is the same reinforcement. Taking, then, the best possible condition, the actual bending moment at its minimum is 25% greater than that given by the code. A similar analysis of the wall-panel moment reveals a somewhat more excessive divergence.

The foregoing presupposes just the proper balance of load over the columns and just the proper deflection to give exactly equal moments at the several sections considered. These are not possible conditions, except for one arrangement of loading; they are, however, the most favorable assumptions possible for the four-way system.

Building codes allow a moment coefficient of $\frac{1}{12}$ for interior slabs. Introducing $0.775\ L$ as the span length, this would be $0.5\ wL^3$ as the moment. Thus the plain-slab designer would have to use 67% more effective steel reinforcement than the flat-slab designer.

The advantage that this code gives to the flat-slab bidder is obvious. It has never been shown, and in fact it is not claimed that a flat-slab over rows of columns



is better conditioned than the same slab on parallel lines of girders. This tremendous advantage would, therefore, appear to be due merely to the placing of some of the rods in a diagonal direction.

This code appears to have been worked up from data obtained by testing floors in buildings and measuring deflections and steel deformations. This kind of testing and deductions made therefrom are misleading and unfair to other systems of design for several reasons:

(1) Only a portion of the floor is ever loaded, and in the nature of the construction the surrounding slab offers large aid to the part tested. Other systems are based on tests of isolated parts.

(2) The tests made are lower stories in buildings where the columns are large and are capable of giving great aid to the slabs not only because of their size, but also because they themselves are only carrying a small part of their load.

(3) The measurements taken are greatly influenced by the tensile strength of the concrete. Users of other systems are compelled to ignore tensile strength in concrete.

The Yale Bowl; an Amphitheater of Earthwork

By Thomas C. Atwood*

SYNOPSIS— [illegible]

Yale is building a new coliseum at New Haven to seat 61,000 spectators. It is built on a different plan from that used on previous structures of this type in this country, being practically a mass-concrete and earthwork structure with the seat slabs laid directly upon the earth, instead of the usual reinforced-concrete slab supported above ground on beams and columns. It is built on a level plain in a similar manner to a cut-and-fill reservoir, the earth being excavated to a depth of about 27 ft. in the center and the material used to form an oval-shaped embankment rising to about 27 ft. above the natural ground and completely surrounding the playing field.

FIG. 1. THE YALE BOWL, A 500x300 FT. FIELD SURROUNDED

The "Bowl" occupies a field of 25 acres, ample room being allowed for entrance and exit of the large crowds. The outside dimensions of the structure are 930 by 750 ft., and the playing field is 500 by 300 ft. The main axis of the field lies about NW and SE so that the afternoon sun in the fall will be at right angles to the side lines and not shine in the players' eyes.

It may be of interest to note that the largest of the ancient amphitheaters, the Colosseum of Rome, had outside dimensions of 620 by 513 ft., with inside dimensions 287 by 180 ft., while the great structure at Pompeii, which the "Bowl" most resembles, is 460 by 345 ft. outside and 217 by 114 ft. inside. The seating capacity of Pompeii was 20,000 and that of the Colosseum 87,000, [illegible]

The location is ideal for such a structure with [illegible] the embankment, the material being a coarse sandy gravel giving perfect natural drainage. It was realized that there will probably be some slight frost action (expected to be very slight owing to the coarseness of the sand), but this and also the danger of unequal settlement in the embankment has been provided for by making the concrete blocks of the seating structure quite small and reinforcing them heavily. The embankment is faced on the outside with grass, the slope being approximately 1 on 2. A retaining wall holding the foot of the slope prevents outsiders from climbing up the bank.

The promenade around the top of the bank and the 50-ft. walk around the outside of the Bowl have a surfacing of broken stone with the interstices filled with screenings, all watered and rolled.

Retaining-Walls

The outer retaining-wall is of the gravity type and is 9 ft. high above ground. It has a gutter cast in the top for carrying off the surplus water from the bank above it. The inner retaining-wall, which defines the playing field, is also of the gravity type and has also a gutter cast in the top for carrying off the water falling on the seats.

Both the inside and outside walls have been built in short lengths with pilasters between, the pilasters being built later and acting as expansion joints.

The public entrances are tunnels cut back into the bank with curved walls connecting their portals to the outside wall.

The inner retaining-wall is surmounted by a concrete parapet wall [illegible] ft. high, which serves as a fence between the seats and the field and is so designed as to appear to lengthen the field wall from the field side and thus give a better architectural effect.

The surface of the concrete has been given a smooth finish by rubbing it up with a [illegible] as soon as the forms were removed, except that the pilasters and coping of the outside wall were brushed up [illegible]

*Construction Engineer, Yale University, [illegible] New Haven, Conn.

TUNNELS

There are 30 tunnels provided for the entrance of spectators, all running from the ground level outside to about the middle of the bank of seats inside. These tunnels are 7 ft. wide and 8 ft. high inside. They were built in the open and the embankment built around and over them. The walls of the tunnels are 15 in. thick and the roof 8 to 15 in. thick. The roof is waterproofed with three layers of tarred felt and one layer of "tartex," each layer being thoroughly mopped with pitch before the next was put on, while a single layer of pitch was mopped onto the sides. The tunnels average about 140 ft. in length, some being longer than others on account of the fact that the outside ground level on the northerly side is lower than on the southerly side, thus lengthening the outside slope and consequently the tunnels.

There are two tunnels which run from the outside ground level to the playing field. One of these, the Main Tunnel, is 15x10 ft.; is on a grade of about 7½%, and has an 8-in. concrete pavement. It will admit the working force to the field and will also serve as an exit for processions and for the large crowds which will come down onto the field after the games. The other, the Players' Tunnel, 10x8 ft., gives access to the players from the south side where the visiting team will have its quarters, and where the large clubhouse for the accommodation of all teams will be built.

All tunnels are lighted by electricity.

SEATING STRUCTURE

The seating structure consists of concrete slabs, as mentioned above, laid directly on the surface of the ground with steps cast in the top and with wooden benches supported over the edge of the concrete steps by steel standards. The present contract provides for placing the permanent seating structure up to the original ground level only, and placing a temporary wooden seating structure above that level. It is expected that this temporary structure will be used only for the Yale-Harvard game on Nov. 21, 1914, and that next year it will be removed and the permanent structure carried to the top of the bank. For the opening game over 75,000 applications for seats were made and in order to accommodate as many as possible 7500 additional temporary seats are being built on the promenade at the top.

The concrete slabs vary in length from 8 to 17 ft., most of the slabs being under 13 ft. long. All except those on the cross-aisle are three steps wide, or 8 ft. overall. They are reinforced in both directions and both top and bottom so as to carry their load if supported only at the edges or only in the middle. One radial joint in the seating slab between each pair of tunnels is filled with Carey's "Elastite" to provide for expansion.

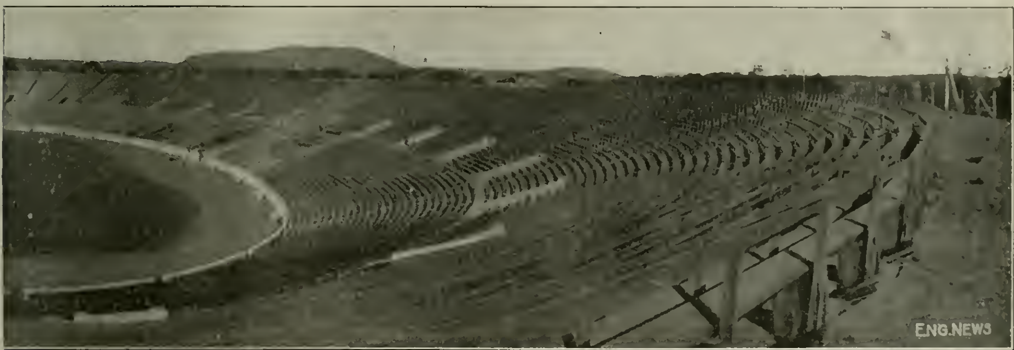
The surface of the steps, both tread and riser, has been given a smooth sidewalk finish with a ½-in. mortar coating placed integral with the concrete. The mortar was colored with lampblack to a dark bluestone, to prevent the glare from the natural cement color.

An aisle leads directly down from the inner end of each tunnel to the playing field, a flight of steps being provided at the foot of the aisle. A cross-aisle connects the inner ends of the tunnels and from this two aisles extend to the top of the bank of seats between each pair of tunnels.

SEATS

The benches are made of 1¾x9¾-in. (finished) planks supported on steel standards or brackets and provided with a back rest consisting of a 1⅛x4¾-in. strip supported on wooden posts bolted to the back side of the steel standard. The steel standards are bolted to the concrete by ⅝-in. Tobin bronze U-bolts. All steelwork is galvanized or sherardized and then painted with a rust-preventive paint. The seat plank is set so that its front edge projects 1½ in. in front of the concrete riser, giving plenty of room for the heels, and it is set so as to slope backward at such an angle so as to give the most comfortable seat. The seat planks are fastened down with lagscrews from underneath so as to leave the top of the seat smooth. The top of the plank is shaped to a special curve determined by experiment and this is thought to be a great improvement in the making of wooden benches. The back rest is curved on the front side so as to have no projecting corners.

The wood for these seats is Douglas fir. This was decided upon after an exhaustive investigation, it being desired to obtain a wood which has a good appearance, which can be obtained in clear lumber and with all vertical grain (to eliminate the picking up of splinters on the top of the seat), and which is as durable as possible.



BY 61,000 SEATS (FROM A PANORAMIC PHOTOGRAPH)

The only woods to fulfill all of these conditions were Douglas fir, Western hemlock and redwood. Redwood was eliminated because it is liable to stain clothing when wet and Western hemlock because it is less durable than the Douglas fir and delivery could not be guaranteed. The only defect allowed in the Douglas fir was a reasonable number of pitch pockets, and trouble from these was eliminated by having the wood kiln dried.

The wood has been treated for preservation by giving it two coats of Carbolineum wood oil, one before erection and one after.

The temporary benches were made similar to those last added to the old wooden football stand, and have a 1⅝x9½-in. spruce seat plank and ⅞x3½-in. spruce back rest. A press box has been built accommodating 100 and provided with ample telephone and telegraph service.

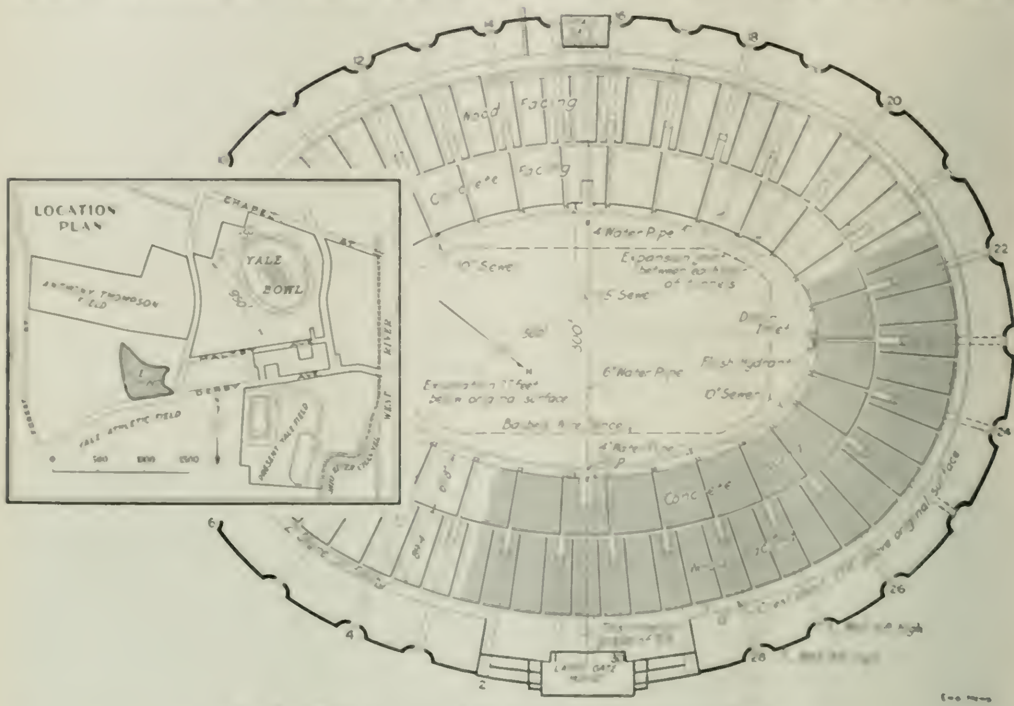


FIG. 2. GENERAL PLAN OF YALE BOWL AND LOCATION PLAN

PLAYING FIELD

The playing field was built on a bed of sand 30 ft. below the original surface of the ground. Special attention was given to designing a field which should be as perfect as possible. It was feared that with the perfect drainage underneath, and only sandy loam to use for surfacing, trouble might be experienced with the field drying out. This condition was met by putting on an extra thick layer of loam (total thickness 18 in.), and mixing into the top layer humus, which is practically a natural leaf mold and has the property of retaining moisture a long time.

FIG. 3. [illegible]

The entire field (and the pipe trenches) were first heavily watered to settle any place which had been accidentally dug below grade, and then an 8-in. layer of black loam was spread and rolled with a 5-ton roller. A second layer was then spread and rolled [illegible] and top dressed to a true surface 17 in. above subgrade. An inch of fertilizer humus was applied and harrowed in, and the surface rolled with a hand roller. Then 2 in. of sod was put on, the field being left 1 in. high to provide for anticipated settlement. The field was turfed the latter part of August except for working space left outside of the gridiron near the wall. Screened loam was spread over the turf and raked in. No further rolling was done until the last of October, when the 5-ton steam roller was put over the field before any practice was allowed on it. The result has been a perfectly smooth field with a fine springy turf.

The field is crowned 12 in. between side walls, 5 in. of this being between the side lines of the gridiron. The crowning was made with a special curve so as to give reasonable drop between the center and side lines without having an excessive drop between the side lines and the wall; it has worked out very well.

Architectural Features

The purely architectural features are in the two large gate-houses, which are expected to be built next year. One of these, the Main Gate House, is 96x47 ft., 42 ft. high, and provides quarters for the home team and for the ticket department. The Small Gate House is 60x43 ft. and 40 ft. high, and provides quarters for the visiting team.

A large stairway is to be built on either side of the Main Gate House, from the top of the bank to the ground, this together with the gate-house providing an impressive feature at the main entrance.

The tunnel portals have been worked out very effectively.

Water-Supply and Drainage

A 6-in. main connected with the city water system is laid into the playing field; a 4-in. main is run around the field and another 4-in. main around the outside of the Bowl. Numerous flush hydrants have been placed to give short lines of hose (2-in.) for watering the grass.

A vitrified drain is laid around the outside of the Bowl and one around the playing field, both emptying into a main drain running to the West River. The water falling upon the seats runs down over the steps to a gutter just in front of the bottom riser, from which it is discharged under the steps leading to the playing field. A small catch-basin located under these steps takes this water and also that which runs off from the playing field.

Automobile Parking Fields

Among the many problems connected with this work, that of handling the enormous traffic was not the least, and the automobile traffic is the most troublesome. The surplus excavation from the Bowl was placed upon the meadow between Yale Ave. and the West River, converting this swamp into 12 acres of good level land, admirably adapted for automobile parking and well above all but extreme floods. This space has been laid out in streets leading to a boulevard along the river, and footpaths between the streets lead toward the Bowl, the arrangement being such that the foot passengers do not cross any street on which the autos travel. Another even larger parking space is provided west of the Bowl.

Fig. 4. General View during Construction of Seatbanks

Contracts

The work has been done under three contracts, all of which were let to the Sperry Engineering Co., of New Haven. The first contract was let in July, 1913, and comprised the main excavation and embankment, the water-supply and drainage systems, the tunnels, and outer and inner retaining-walls. The second contract, let in July, 1914, comprised the seating structure and the parapet walls. The third contract, let in September, 1914, comprised the finishing up of the exterior grading and laying of macadam walks. Work was started on all of these contracts immediately after letting, and they are now practically completed.

Hon. T. De Witt Cuyler is Chairman of the Yale Committee of Twenty-one, Inc., for whom the Bowl is being

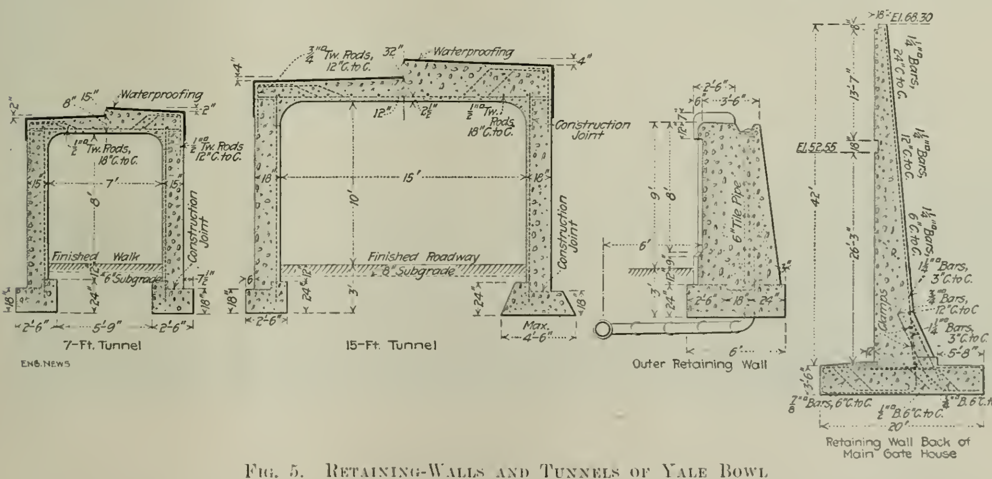

Fig. 5. Retaining-Walls and Tunnels of Yale Bowl

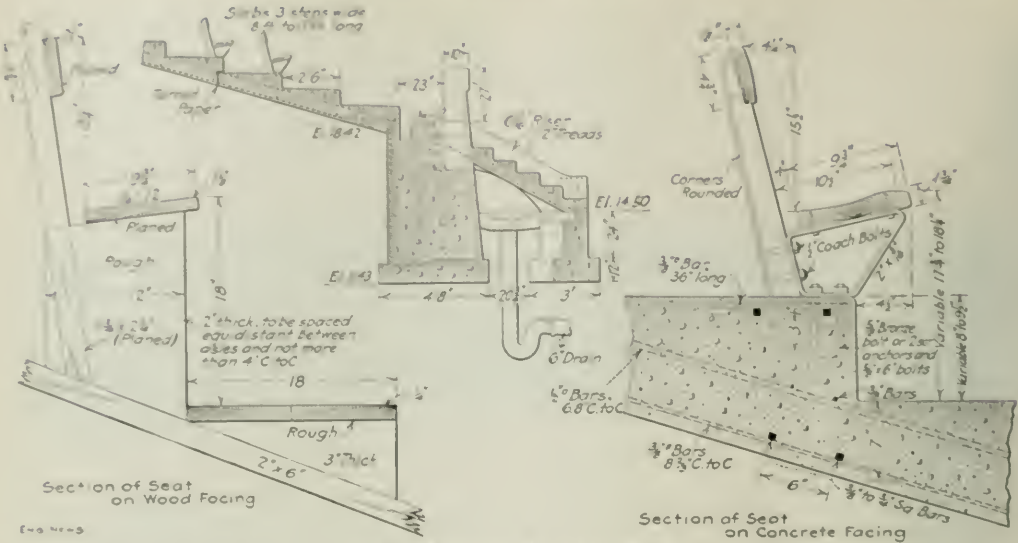

FIG. 6. SEATBANK SLAB AND SEATS

(Seating plank in permanent part of bank was shaped to special curve determined by experiment. The seats are fitted with backs—another unusual feature.)

built. The writer is Supervising Engineer, and C. A. Ferry, who conceived the original design of the Bowl, Resident Engineer. Edward G. Williams, of New York, is Advisory Engineer and Donn Barber, of New York, is Consulting Architect. David Daggett, of New Haven, Secretary of the Committee of Twenty-one, is Chairman of the Structures Committee. The playing field and details of the seating structure have been under the personal supervision of Everett Thompson, Assistant Secretary.

Clearing the Slide in the Panama Canal

We briefly noted on p. 852 of our issue of Oct. 22, the closing of the Panama Canal through Culebra Cut on Oct. 14 and the opening of a channel through it in five days by the canal dredges. A fuller account of the slide and its removal is given in the Canal Record of Oct. 21. We abstract it as follows:

A large slide on the east bank of Culebra Cut, directly north of Gold Hill, [illegible]

[illegible]

FIG. 7. EMBANKMENT OF YALE BOWL DURING CONSTRUCTION

[illegible]

Electric Storage Battery Vehicles [illegible]

The dredges were worked under triple shift. The 15-yd. dipper dredges "Gamboa" and "Paraiso" and the 5-yd. dipper dredge "Mindi" began excavation at the north side of the slide during the night of Oct. 14-15, while the mass was still in motion. The dipper dredge "Cardenas" was added to the fleet on Oct. 15, and during the 16th an extension of discharge pipe was laid from a point opposite Cucaracha slide, which allowed the pipe line suction dredge "No. 86" to take part in the work.

The channel was cleared sufficiently by noon of Oct. 20 to allow the passage during the afternoon of seven vessels, which had been delayed at the south end of the canal. The actual passage of the seven through the cut occupied about four hours; they followed each other at intervals of about half an hour, propelled by their own power, but passing the slide under the control of a tug fore and aft, to hold them to the course. Thirteen vessels were awaiting passage from the Atlantic entrance; nine of them were transferred to the anchorage basin in Gatun Lake, south of Gatun Locks, on Oct. 20, and are being handled through the cut today.

The slide which blocked the canal is 2100 ft. long, and broke back about 1000 ft. from the center line of the channel. It occurred in a part of the bank, formerly involved in the east Culebra slide, and is designated as the "New Culebra" slide. The old slide appeared to be dead, and the channel opposite it had been cleared to almost full width and depth. At the present time, no further movement is indicated, but practically all of the 725,000 cu.yd. involved in the movement of Oct. 14-15 will have to be dredged from the prism, which may cause further motion. The material is masses of rock and earth, in about equal proportions.

Following the preliminary survey made on the morning of Oct. 15, after the slide had come to rest, it was estimated that, unless further movements occurred, the channel could be opened in one week. A still later estimate set Oct. 22 as the first day on which vessels could pass the slide. The performance of the dredging forces in clearing the channel in two days' less time than was believed to be necessary indicates the fitness of the equipment and the loyal persistence of the personnel.

The excavation accomplished by the dredges at the base of the slide, in periods ending at 8 a.m. of each day named, was, in cu.yd.:

Dredge	15th	16th	17th	18th	19th	20th	Total
"Gamboa"	3935	5,160	6,175	6,910	7,800	5,775	35,755
"Paraiso"	4150	6,900	7,625	7,600	6,720	4,975	37,970
"Mindi"	1845	1,000	2,403	2,709	1,640	2,137	11,734
"Cardenas"	....	3,027	3,251	2,031	3,210	2,052	13,571
"No. 86"	....	....	3,825	5,850	6,250	4,650	20,575
Total	9930	16,087	23,279	25,100	25,620	19,589	119,605

The maximum day's output was 25,620 cu.yd. in the period ending at 8 a.m., Oct. 19, or Sunday, when the dredge and towboat crews appeared for duty, without orders or instructions.

On Oct. 31 another slide occurred in the same material north of Gold Hill and blocked the Canal until Nov. 4, when the dredges had cleared the cut sufficiently to allow vessels to pass.

Defeat of Municipal Bond Issues at Dayton, Ohio

The defeat of bond issues for grade-crossing elimination, a municipal electric-light plant and parks and playgrounds by popular vote at Dayton, Ohio, on Nov. 3, was caused by a number of conditions of more than local interest. These conditions are set forth in the following notes sent to Engineering News by S. H. Ankenny, Publicity Manager of The Greater Dayton Association:

Inasmuch as the "Dayton Plan" of municipal government is a subject of great interest at the present time, you may be interested in knowing the result of the first election, at which several municipal issues were at stake, since this form of government has come into power here.

About a month ago, the city commission put up to the people for ratification at the election on Nov. 3, two bond issues: one for $250,000 to be used in buying several dumps and improving them for parks and playgrounds, the other for $1,000,000 to be used in defraying the city's share (35%) of the cost of elevating the joint railroad tracks through the heart of the city.

At about the same time the socialist party, which has been against the new form of government from the first, petitioned the city commission to bring before the voters a bond issue for $500,000 to construct and operate a municipal electric-light plant. The city commission turned this proposition down, believing it would be financially inexpedient to engage in the electric-light business in competition with a private corporation which is now rendering adequate service at a fairly reasonable rate. This corporation has $8,000,000 invested in its local plant and, consequently, a half-million dollar plant would be at a great disadvantage and would be inadequate to meet the needs of all but a small portion of the city. The socialists took the proposition over the heads of the city commission by securing enough signatures to their petition to demand a referendum.

At the same time, the Greater Dayton Association began an active campaign for the passage of the bond issues for parks and playgrounds and grade-crossing elimination, and the defeat of the bond issue for the municipal electric-light plant. The vote Tuesday had the following results:

	For	Against
Parks and playgrounds..............	9,784	16,931
Grade-crossing elimination...........	10,453	15,871
Municipal light plant................	9,193	13,174

From these results it is seen that all of the propositions were defeated. While the city commission lost its proposed bond issues for parks and playgrounds and track elevation, it secured the indorsement of the voters in turning down the municipal electric-light plant.

The one great factor in the adverse vote on the bond issues was the present business conditions and the feeling of financial stringency prevalent throughout the country. There was also sectional opposition, as some parts of the city were opposed to track elevation because the plan did not include the elimination of grade crossings in these suburban districts. Other parts of the city were well provided with parks and, therefore, took an independent attitude upon this question. The municipal light plant, of course, attracted a large number of voters who favor municipal ownership in any form without regard to the reasonableness of the question at hand.

The result of the vote is not considered unfavorable to the city commission. In fact, it puts the present administration in a better position than it was previous to the election, inasmuch as there has been considerable agitation for track elevation and parks and playgrounds, and now all responsibility for failure to secure these things has been placed upon the people at large. There would undoubtedly have been criticisms of the city administration if these questions had not been put before the voters at this time.

NEWS NOTES

Bridge Falsework Was Washed Out at the new Milwaukee Bridge over the Chehalis River, at Mays, Wash., on the Puget Sound & Willapa Harbor Ry. The accident was caused by a log jam.

A 6½-Ft. Rise in the South Canadian River carried out six bents of a timber bridge on the Rock Island Lines, at Bridgeport, Okla., on Oct. 25. Two other similar accidents have occurred this year at the Bridgeport bridge.

A Fire at the New York Dock Co., Brooklyn, N. Y., early on Nov. 9, destroyed a nine-story brick building which contained the machinery for operating two adjoining grain elevators. The origin of this fire is unknown, as was that of the destructive pier fire of the Sicula-Americana line ("Engineering News," Nov. 5), which occurred on Nov. 4, within 150 ft. of the present blaze. The damage caused by the New York Dock Co. fire is estimated at $100,000.

A Collision of Electric Street Cars at Chicago occurred Nov. 3 in the Van Buren St. tunnel under the Chicago River. The tunnel has grades of 6.32% on the west and 11.06% on the east (Engineering News, Sept. 13, 1906). A car that had just passed the center of the tunnel and started up the eastern grade was stalled by the trolley pole jumping off the wire. The rules require that in such cases the conductor shall go back to stop following cars, but in this case the conductor at once mounted to the roof of the car to replace the trolley. Owing to the steep grades, the roof of the tunnel hid the standing car from the motorman on the next car until it was too late to stop, and it is reported that the air-brake did not work properly. One man was killed and five persons were injured. The conditions of steep grades and heavy traffic in the three Chicago River tunnels of the street-railway system would seem to call for the installation of some automatic block-signal system to indicate to each car its clearance from the car preceding.

A Convention of Alabama City Officials has been called by [illegible] of Alabama [illegible] for the purpose of [illegible] League of Municipalities. Address [illegible] of Engineering.

Buffalo, N. Y., Adopted Commission Government by [illegible] on Nov. 3. The general principle was approved [illegible] a few years ago, but it was not until [illegible] charter bill could be got through the [illegible]. [illegible] the bill was vetoed by the [illegible] the vote. (Legislation affecting [illegible] in New York State goes to the mayor for action.)

A Third High-Level Bridge across the Cuyahoga River valley at Cleveland, Ohio, was authorized by a county referendum [illegible] Nov. 3. While it is expected that the [illegible] Lorain Ave. route will be selected, the County Commissioners have asked the city and federal authorities to cooperate in picking [illegible] route which not only will give a desirable crossing but [illegible] to the necessary straightening of the Cuyahoga River. The [illegible] vote authorized a [illegible] bond issue.

Work on the Badin Hydro-electric Development of the Southern Aluminum Co., near Whitney, N. C., is reported to [illegible] although in an advanced stage on a [illegible]. As noted in "Engineering News," June 1, 1911, some 12,000 hp. was being made available for smelting operations. The project was being promoted by [illegible] French [illegible] and the engineers in charge of design and construction are reported to have returned to France.

The Ontario "Hydro-radial" Electric Railway Scheme, proposed to be built jointly by several municipalities and the Hydro-electric Power Commission (as noted in "Engineering News," April [illegible], 1914, p. [illegible]) were approved on Oct. [illegible] at elections in [illegible] towns out of 13 involved. The interurban lines under discussion at present extend from Toronto to Newmarket and Port [illegible], about 2[illegible] and 3[illegible] miles respectively. The construction work must wait on securing a promised provincial subsidy.

Stockton St. Tunnel Delayed by Strike—Work on the Stockton St. tunnel, San Francisco, described in "Engineering News," Jan. [illegible], 1914, p. 1[illegible], has been delayed by a strike of the local Plasterers' Union. This organization is dissatisfied [illegible] the tunnel is not plastered in accordance with the [illegible] of the plasterers, who would like the city to [illegible] to give the interior lining a smooth [illegible], despite the fact that it will probably be lined with [illegible] in the near future.

Bonds for Sewage-Treatment Works at Norristown, Penn., were defeated by a majority vote of three to one, on Nov. 3. The vote appears to have been [illegible] a defiance of the Pennsylvania State Department of Health, which we understand had ordered the Borough of Norristown to provide [illegible] works. [illegible]

Prizes for Essays on Highway Construction [illegible]

Freight Rates on Long and Bulky Materials [illegible]

A Tunnel in the City of San Francisco [illegible] Pacific Exposition has been given a rate of [illegible] per car for exhibits. The bore is [illegible] ft. in length and extends from Van Ness Ave. through Fort Mason [illegible]. Bates, Borland & Ayer are the contractors.

The Reconstruction of the Missouri River Bridge of the Chicago, Burlington & Quincy R.R. at Kansas City, Mo., has been contemplated, and some study of the situation has been made by the railway company, but we are informed officially that there is no prospect of any work being done in the near future, especially in view of the present financial situation. The general plan is said to be to construct a new double-track bridge a short distance upstream from the present single-track bridge. This present bridge is quite strong enough for the modern equipment, but the main purpose of a new structure would be to increase the train capacity by means of a double track. The old bridge, known as the Hannibal Bridge, was built in 18[illegible], but its superstructure was rebuilt in 1891. It has six fixed truss spans and a swing span.

More Rapid Reinforced-Concrete Construction—In our issue of Nov. 12, 1914, p. 966, we noted a large concrete warehouse in Brooklyn on which very rapid work was done. We now have to report similar fast construction on the new building now nearing completion for the Stanley Works at New Britain, Conn. This building, which is being put up by the Aberthaw Construction Co., of Boston, measures 63x2[illegible]3 ft., seven stories and basement. Ground was broken during the first week of August, the foundations poured on Aug. 2[illegible] to Sept. 11, the first-floor slab on Sept. 14 to 16, the second-floor slab Sept. 17 to 19, the third-floor slab on Sept. 24 to 2[illegible], the fourth-floor slab on Oct. 1 to 5, the fifth-floor slab on Oct. [illegible] to 12, the sixth-floor slab on Oct. 15 to 21, the seventh-floor slab on Oct. 24 to 2[illegible]. Roof centering was erected Oct. 2[illegible], and the last section poured Nov. 5.

The Flood Prevention Committee of the Miami Valley, Ohio, has decided to complete plans for flood protection without waiting for the final court decision on the legal questions involved, and the following men have recently joined the staff of the Morgan Engineering Co., which is making these plans: J. H. Kimball, M. Am. Soc. C. E., formerly Acting Chief Engineer for the Commissioners of Sewerage of Louisville, Ky.; B. M. Jones, formerly with the Electric Bond & Share Co., New York City; Walter M. Smith, M. Am. Soc. C. E., formerly Designing Engineer, and H. S. R. McCurdy, M. Am. Soc. C. E., formerly Division Engineer of the Board of Water Supply of New York City; Alfred B. Mayhew, Assoc. M. Am. Soc. C. E., formerly Designing Engineer on Arrowrock Dam, Idaho, U. S. Reclamation Service; S. M. Woodward, M. Am. Soc. M. E., Professor of Hydraulics, Iowa State University. Final hearing before the Supreme Court of Ohio on the constitutionality of the Ohio Conservancy Act will be held Nov. 12.

An 8-ft. Waterway in Illinois, connecting the Chicago drainage canal with the Illinois River, has been proposed as a substitute for the former projects for waterways having depths of 14 and 2[illegible] ft. to the Mississippi River. A report on this new project has been made to Governor Dunne by a board of engineers composed as follows: [illegible] [illegible]

The Specifying of a Patented Pavement by the city of [illegible], N. Y., has been upheld by the New York Supreme Court [illegible]

A 2,500,000-gal. Steel Water Tank, 100 ft. in diameter and 44 ft. 3 in. high, is being built by the Massachusetts Metropolitan Water Board, on Belleview Hill, in West Roxbury, to serve as a reservoir for the Southern Extra High Service. The concrete foundation has been completed by John E. Palmer, Boston, Mass., and the work of erecting the steel is being done by Walsh's Holyoke Steam Boiler Works, Holyoke, Mass. The bottom of the tank, which rests directly on the concrete foundation, is of ⅜-in. plates, while the side plates vary from ⅞-in. at the bottom to ⅜-in. at the top, there being seven courses. The horizontal lap joints are double riveted and the vertical butt joints have plates on both sides with special rivet arrangements. The lowest course of side plates is connected to the bottom by means of 6x3½x¾-in. Ls and the top of the tank is stiffened by 3x⅜-in. Zs. The steel for the plates conforms to the Standard Specifications of the American Society for Testing Materials for flange steel, except that the tensile strength is required to be between 57,000 and 62,000 lb. per sq.in. The butt joints are planed so as to be in perfect contact throughout and all calking edges are beveled. Rivet holes in all plates thicker than ⅜ in. are either drilled from the solid or punched $\frac{3}{16}$ in. smaller and reamed.

PERSONALS

Mr. Ralph H. Wilson has been appointed Advertising Manager of the Walter A. Zelnicker Supply Co., St. Louis, Mo.

Mr. W. L. Schneider has been appointed Inspector of Transportation of the Delaware & Hudson Co., with offices at Albany, N. Y.

Mr. S. E. Hutton, M. Am. Inst. E. E., Consulting Engineer, of Moscow, Idaho, has been appointed Engineer of the Public Utilities Commission of Idaho.

Mr. Olin H. Landreth, Professor of engineering at Union College, Schnectady, N. Y., has been elected a district delegate to the State Constitutional Convention.

Mr. M. F. Clements, M. Am. Soc. C. E., of Ridgefield, Wash., has been appointed Engineer in charge of track elevation of the Northern Pacific Ry. at Spokane, Wash.

Mr. H. N. Underhill, formerly with the Underpinning & Foundation Co., New York City, is now associated with the MacArthur Concrete Pile & Foundation Co., 11 Pine St., New York City.

Mr. H. M. Sperry, M. Am. Soc. C. E., for many years Sales Engineer of the General Railway Signal Co., Rochester, N. Y., has been appointed Manager of the department of publicity and education recently organized by his company.

Mr. R. J. Potts, former Professor of highway engineering at the Agricultural and Mechanical College of Texas, and recently with the Potts-Moore Gravel Co., Waco, Tex., has been appointed Engineer of the proposed country drainage district, including part of the City of Waco.

Mr. Elmer Ambrose Sperry, M. Am. Inst. E. E., of New York City, has been awarded the John Scott Legacy Medal and Premium by the City of Philadelphia, acting on the recommendation of the Franklin Institute. Mr. Sperry is made this award in recognition of his gyro compass.

Mr. M. Liebel, Jr., President of the Liebel-Binney Construction Co., General Contractors, Erie, Penn., has been elected a member of Congress from the 25th Pensylvania district. Mr. Liebel is also President of the Vulcan Rubber Co. and is identified with many manufacturing interests in Erie.

Mr. A. C. Bradley, recently Road Master of the Chicago, Rock Island & Pacific Ry. at Iowa City, Iowa, has been appointed Division Engineer of the Oklahoma division, with headquarters at El Reno, Okla., succeeding Mr. Garrett Davis, who has been transferred to the valuation work of the railway.

President R. C. Sturgis, of the American Institute of Architects, has appointed the following members of a committee to act in an advisory capacity to the Lincoln Highway Association: Messrs. Elmer C. Jensen, of Chicago, Ill ; Wilbur T. Mills, of Columbus, Ohio, and Benjamin Hubbell, of Cleveland, Ohio.

Mr. E. N. Brown, for many years President of the National Rys. of Mexico, has resigned. He has been connected with the construction and operation of the Mexican Rys. since 1887, when he was Engineer in charge of construction of the railway from Saltillo to San Luis Potosi. Later he was made Division Superintendent of this division.

Mr. Garrett B. James, of the engineering staff of the Underwriters Laboratories, Chicago, Ill., has been appointed Consulting Engineer of the U. S. Bureau of Mines, to carry on an investigation of the subject of oil fires. Mr. James has been granted a three months' leave of absence by the Laboratories and is now in the Texas oil fields.

Messrs. C. S. Rindsfoos, recently Secretary-Treasurer of the Foundation Co., New York City, and N. C. Fallor, recently Manager of the machinery department of the Canadian Fairbanks-Morse Co., Montreal, Que., announce that they have formed the United States Purchasing Corporation, with offices in the Woolworth Building, New York City.

Mr. Lynn E. Perry, Jun. Am. Soc. C. E., has been admitted to the firm of Oldfield & Brady, Cairo, Ill. The firm will be known under its present name. Mr. Perry was formerly with the staff of the New York City Board of Water Supply and the Philadelphia Bureau of Surveys. He will take charge of sewer and drainage projects soon to be begun by the firm.

Governor Haines, of Maine, has appointed three lawyers, Messrs. Benjamin F. Cleaves, of Biddeford; William B. Skelton, of Lewiston, and Samuel W. Gould, of Skowhegan, members of the State Public Utilities Commission, created by the new law which went into effect Oct. 30. The salary of the chairman is $5000 per annum, and of the other two members, $4000 per annum.

Mr. John M. Rapelje, recently Assistant General Manager of the Northern Pacific Ry. at St. Paul, Minn., has been promoted to be General Manager of the lines east of Paradise, Mont., succeeding the late E. A. Goodell. Mr. Rapelje was born in Canada in 1857 and began his railway experience as a brakeman on the Grand Trunk Ry. In 1898 he was a conductor with the Northern Pacific.

Mr. H. S. Van Scoyoc, Assoc. M. Am. Soc. C. E., recently Inspecting Engineer of the Canada Cement Co., Ltd., Montreal, Que., has been appointed Chief Engineer of the Toronto-Hamilton Highway Commission, which is to build a new highway between Toronto and Hamilton, Ont. Mr. Van Scoyoc was born in Philadelphia, Penn., and is a graduate of the University of Pennsylvania.

Mr. J. Vipond Davies, M. Am. Soc. C. E., Vice-President of Jacobs & Davies, Inc., Consulting Engineers, 30 Church St., New York City, has been awarded the Telford Gold Medal of the Institution of Civil Engineers, London, England, for his paper on the "Extensions of the Hudson River Tunnels of the Hudson & Manhattan R.R." This is the most coveted honor conferred by the Institution of Civil Engineers for the literary and professional accomplishments of its members.

Mr. F. C. Magruder, Assoc. M. Am. Soc. C. E., who for the past 11 years has been with the United States Reclamation Service, having been in charge of the Belle Fourche Project in South Dakota for the past four years, and Stephen C. Berry, also formerly with the U. S. Reclamation Service, have formed a partnership to engage in the general practice of engineering at Belle Fourche, South Dakota. Special attention will be given irrigation systems, drainage systems and municipal water-works.

Mr. Walter T. Spencer, Assoc. M. Am. Soc. C. E., former Division Engineer of the New York, New Haven & Hartford R.R. at Waterbury, Conn., and Providence, R. I., has been promoted to be Division Superintendent of the Old Colony division, with headquarters at Taunton, Mass., succeeding Mr. H. C. Oviatt, promoted. Mr. Spencer was born in 1869 and graduated from Sheffield Scientific School, Yale University, in 1890. He was Division Engineer from 1893 until September, 1914, when he changed to the operating department as Trainmaster at Providence, R. I.

Dr. J. A. L. Waddell and Mr. John Lyle Harrington, M.'s Am. Soc. C. E., announce the dissolution of the firm of Waddell & Harrington. The firm's business will be conducted as usual until the conclusion of its affairs in July, 1915, except that it is accepting no new commissions. Dr. Waddell will give his attention to special engineering and financial matters and to important advisory work. Mr. Harrington will be joined by the firm's Associate Engineers, Messrs. E. E. Howard, M. Am. Soc. C. E., and Louis R. Ash, M. Am. Soc. C. E., in the establishment of the firm of Harrington, Howard & Ash, Consulting Engineers. Mr Howard has been associated with Dr. Waddell for 14 years; for many years he was Principal Assistant Engineer and later Associate Engineer of the firm of Waddell & Harrington. Mr. Ash was formerly City Engineer of Kansas City, Mo., which office he resigned to become Associate Engineer and Office Manager of Waddell & Harrington. The new firm of Harrington, Howard & Ash is already engaged in a general consulting practice, including the design and construction of movable bridges. The principal office of the new firm is 1012 Baltimore Ave., Kansas City, Mo.

OBITUARY

Charles J. [illegible], a mining engineer, of San Francisco, Calif., died Nov. 1.

William H. [illegible], Treasurer and Superintendent of the [illegible] & Boiler Co., Cleveland, Ohio, died Oct. 9.

John Kilgour, former President of the Cincinnati Street Ry. Co., died Oct. 27, at his home in Cincinnati, Ohio, from [illegible]. He was [illegible] years old.

Charles O. Kruger, President of the Philadelphia Rapid Transit Co., died Nov. 1, in the rooms of the Racquet Club. He was born in Philadelphia in 1861.

Charles M. Gould, Vice-President and Treasurer of the Gould Coupler Co. and the Gould Storage Battery Co., New York City, died Oct. 20 at his home in Bayside, Long Island. He was born in Buffalo, N. Y., in 1873. He was the son of Charles A. Gould, founder of the company.

Emil Kuichling, M. Am. Soc. C. E., one of the best known American hydraulic engineers, died on Nov. 9, at his home in New York City. Mr. Kuichling was born at Kehl, Germany, Jan. 26, 1848. In his early youth he came to the United States and was graduated from the University of Rochester as a civil engineer in 1868; he later studied at Carlsruhe, Germany. His early engineering work was in connection with the New York State canals, of which he was chief engineer from 1880 to [illegible]; since that time he has been in consulting practice in New York City. A more extended biography of Mr. Kuichling will appear in our next week's issue.

F. Augustus Heinze, M. Am. Inst. M. E., owner of large copper interests in the West, died Nov. 4, at his home in Saratoga, N. Y. He was born in Brooklyn in 1869 and was educated at the Brooklyn Polytechnic Institute and the Columbia University College of Mines, where he graduated in [illegible]. After studying some time in Germany, he went to Montana, where he became, when not more than 30 years old, a prominent figure in the copper mining industry. Of late years he gained considerable notoriety because of his connection with several banking institutions, and he was indicted by a federal grand jury for mismanagement of the Mercantile National Bank, New York City.

Henry Gannett, Geographer of the U. S. Geological Survey, [illegible] one of the founders of the National Geographic Society, died at his home in Washington, D. C., Nov. [illegible]. He was the father of Farley Gannett, Assoc. M. Am. Soc. C. E., [illegible] of the Pennsylvania Water Supply Commission. Henry Gannett was born in Bath, Maine, in 1846. He graduated from Lawrence Scientific School, Harvard University, in [illegible]. He served as a topographer on the Hayden survey of the territories before the formation of the U. S. Geological Survey. [illegible]

ENGINEERING SOCIETIES

COMING MEETINGS

[illegible]

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.
Dec. 1-4. Annual meeting at New York City. Secy., Calvin W. Rice, 29 W. 39th St., New York City.

AMERICAN INSTITUTE OF ARCHITECTS.
Dec. 2-4. Convention at Washington, D. C. Secy., D. Knickerbacker Boyd, The Octagon, Washington, D. C.

ASSOCIATION OF AMERICAN PORTLAND CEMENT MANUFACTURERS.
Dec. 7-11. Annual meeting in New York City. Secy., Percy H. Wilson, Bellevue Court Bldg., Philadelphia, Penn.

AMERICAN MINING CONGRESS.
Dec. 7-11. Annual meeting at Phoenix, Ariz. Secy., J. F. Callbreath, Denver, Colo.

NATIONAL SOCIETY FOR THE PROMOTION OF INDUSTRIAL EDUCATION.
Dec. 9-12. Convention at Richmond, Va. Secy., C. A. Prosser, 140 W. 42d St., New York City.

SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS.
Dec. 10-11. Annual meeting at New York City. Secy., D. H. Cox, 29 W. 39th St., New York City.

AMERICAN ROAD BUILDERS' ASSOCIATION.
Dec. 14-18. Convention at Chicago, Ill. Secy., E. L. Powers, 150 Nassau St., New York City.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.
Dec. 28-30. Annual meeting at Madison, Wis. Secy., F. M. White, Madison, Wis.

Society for the Promotion of Engineering Education.—The annual meeting will be held at the Iowa State College, Ames, June 22-25. The Secretary is H. H. Norris, 29 W. 39th St., New York City.

American Institute of Consulting Engineers.—The following questions will be considered, at a meeting of the Institute to be held at 8 p.m., Nov. 12, at the City Club, New York City: "A Memorial to Alfred Noble"; "Legislation for the Registration of Engineers"; "The Coming Constitutional Convention in New York State."

Pan-American Scientific Congress.—The United States through the Department of State has invited all the governments of this hemisphere to a Pan-American Scientific Congress, to be held in Washington, D. C., in October, 1915. The first congress of this kind was held in Santiago, Chile, Dec. 5, 1908. The business enacted will be of a general scientific nature, including a department of engineering. The five national engineering societies of the United States, Civil, Mining, Electrical, Naval Architects, and Mechanical Engineers, have been invited to assist in the preparation of the program on engineering. It is believed that this assistance should include suggestion of authors of papers, suggestion of names of the biggest men in the engineering field in the different countries, and urge their appointment as delegates to the congress, and to see that adequate reception for them is provided by the industrial [illegible] of the United States.

American Road Congress.—The [illegible] of these congresses opened on Monday, Nov. [illegible], with a registration of [illegible]. The first session was addressed by Governor Slaton and Senator Hoke Smith, of Georgia, and by Mayor Woodward, of Atlanta. At the same session Logan Page, Director, Office of Public Roads, Washington, D. C., said:

American Concrete Institute.—[illegible]

Engineering News

VOLUME 72 NOVEMBER 19, 1914 NUMBER 21

Erecting the Snake River Viaduct: O.-W. R.R. & Nav. Co.

By W. J. Howard*

The new Snake River cutoff of the Oregon-Washington R.R. & Navigation Co., between Hooper and Ayer, Wash., is a single-track line 17 miles long, which reduces the distance between Spokane and Walla Walla by 30 miles and reduces the grades so that the standard trainload can be increased from 30 cars to 40 loaded cars. This line was put in operation on Oct. 1, 1914.

The construction of the line presented many difficult problems. In the 14 miles from Hooper to the Snake River there are seven tunnels (three on a 6° curve) and four bridges. Three of the bridges cross the Palouse River, which the road follows for the first 11 miles, and which is a small stream in a cañon 50 to 150 ft. wide at the rim and 50 to 280 ft. deep. As the work reached a bridge site, the erection contractor built the bridge, allowing the construction outfit to cross the cañon and continue the work to the next bridge site.

The Snake River Viaduct, which is the last and longest of the bridges, is an important structure, 3920 ft. long, with a maximum height of 300 ft. above the water. It is composed as follows: Five 60-ft. and eighteen 80-ft. deck-girder spans, three riveted-truss deck spans of 226 ft., one of 206 ft. and one of 246 ft. This last was over the low-water channel and was the center one of the five truss spans.

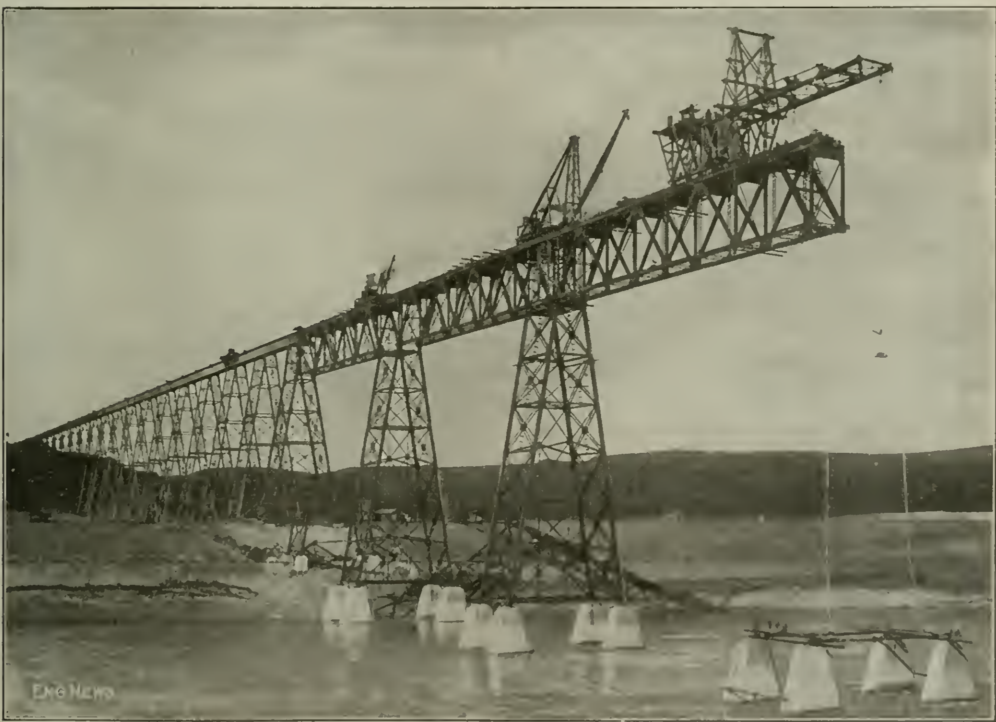

Fig. 1. Cantilever Erection of the 246-Ft. Truss Span of the Snake River Viaduct: O.-W. R.R. & Nav. Co. (300 Ft. above the Water)

(This shows the traveler, the large derrick car and the small derrick car. This last, with a dinky locomotive, delivered material from the bridge yard. On the river bank may be seen the pedestals and base of the temporary steel tower used at the middle of the first truss span.)

Erection of the East Viaduct Approach

The erection beginning at the Hooper (or Spokane) end consisted of three 60-ft. and fifteen 80-ft. deck-girder spans, and 18 four-post towers with their 40-ft. girder

*Engineer, Kelly-Atkinson Construction Co., Chicago.

bays. The height of the towers increased from 33 to 180 ft. The erection of this approach to the truss spans was started Feb. 18, 1913, and completed May 26, 1913. Fig. 1 shows the truss spans under erection and the viaduct approach completed at the Spokane end.

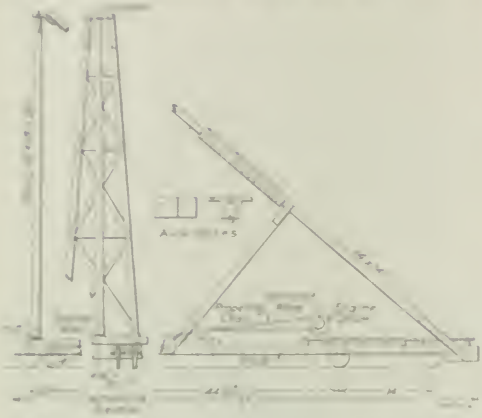

FIG. 2. SELF-PROPELLING DERRICK CAR FOR THE ERECTION OF THE SNAKE RIVER VIADUCT

The rig used was a "mule" traveler or derrick car 70 ft. long and 12 ft. wide, with a deck of 9x18-in. timbers. This is shown in Fig. 2. It was mounted on four sets of wheels, each consisting of four car-wheels on a $4\frac{1}{4}$-in. axle, the two inner wheels being on a gage of 4 ft. $8\frac{1}{2}$ in. and the two outer wheels on a gage of 10 ft. Two sets of idler wheels (with no flanges) were also provided on the 10-ft. gage. The A-frame was of 14x14-in. timbers spread 11 ft. c. to c. at the sill and about 4 ft. at the head frame or spider. The stiff-legs were 14x14-in. timbers, spliced, their lower ends bolted to the deck, behind the engine, and their upper ends bolted to the gooseneck plates. The mast was a 50-ft. timber 18x18 in., with its foot set in a standard derrick shoe and its head having a 5-in. gudgeon pin fitted to a hole in the spider, which was built of channels and plates. The boom was a 72-ft. timber 16x16 in., trussed on four sides with 4x12-in. timbers blocked out at the center and quarter points. It was swung by lines led to a niggerhead on the engine.

This rig was built on the ground from timbers that were at hand, which accounts for its ungainly appearance. The hoisting engine had cylinders $8\frac{1}{4}$x10 in., and the first of its three drums was replaced by a split sprocket wheel placed on the drum shaft. A similar sprocket wheel was placed on the axle of the second set of wheels under the front end of the derrick car. These wheels were connected by a 1-in. chain, and in this way the rig was made self-propelling.

The steel for this east approach viaduct was unloaded at Hooper, the yard at the bridge site not being ready to receive it and the foundation contractors requiring all the car space available for their own equipment. The steel was loaded as required by the yard derrick, and taken to the bridge site by a "dinkey" or small locomotive and a derrick car, and the latter unloaded the material upon a temporary platform. The large derrick car then backed up to the platform (about 200 ft.), picked up the steel, ran it forward and erected it in place.

In the first place, the nearest bent for the towers was erected complete, then the girders of the end span were placed, and the derrick moved out on them to complete the tower. The bents for the higher towers, or those having two or more sections, were guyed longitudinally at the column splices before the car moved ahead to complete the tower.

It was necessary to enthaul the columns of the first

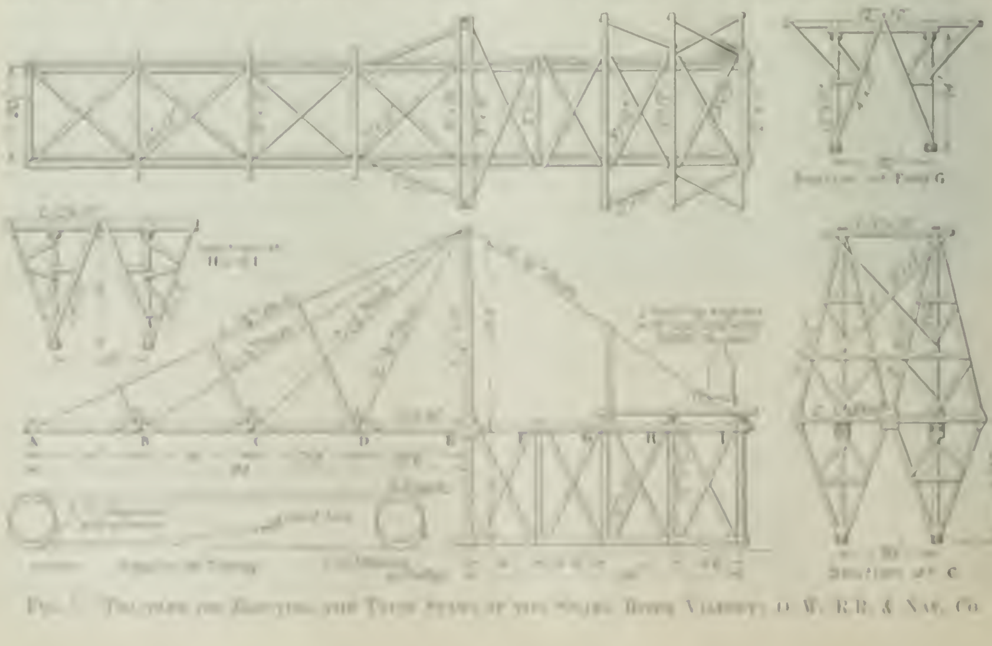

FIG. 3. TRAVELER FOR ERECTING THE TRUSS SPANS OF THE SNAKE RIVER VIADUCT; O. W. R.R. & NAV. CO.

bent of each tower in the 80-ft. spans, the longest outhaul being 21 ft. However, this gave no trouble as there was plenty of drift or leeway.

After the erection of this approach the work was delayed until December, 1913, on account of changes in the plans and by shop delays.

Erection of the Truss Spans

The truss spans were erected as cantilevers, except that the first span had a temporary tower at mid-length. In December, 1913, the erecting contractor started to frame the traveler shown in the accompanying Fig. 3, this is shown also in the view, Fig. 1. The traveler had two 94-ft. horizontal booms for trolleys; these were spaced 20 ft. c. to c., which was the spacing of the top chords of the spans. It was framed and assembled on shore before being erected in place on the completed half of the first 226-ft. truss span.

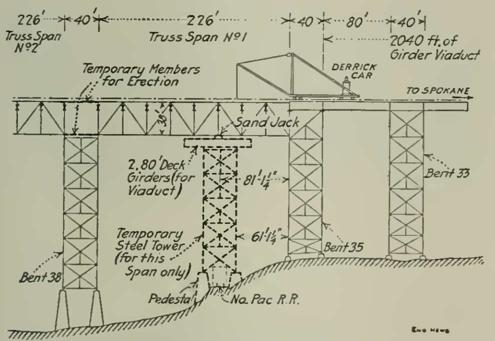

Fig. 4. Temporary Tower Used to Support the First Half of the First Truss Span

This part of the truss span had been erected with its shore end on its permanent tower. The outer end was supported by a temporary tower, as shown in Fig. 4. This tower was composed of parts of one of the river towers capped with two 27-ton 80-ft. girders for the first girder span next to the truss spans at the opposite end of the bridge. These girders were specially designed and made about 7 tons heavier than the rest of the 80-ft. girders, for the purpose of using them to cap the temporary tower and support the projecting end of the truss span. They were the heaviest single pieces handled, with the exception of the 31-ton erecting devices. The temporary tower was erected by the big "mule" derrick car (Fig. 2).

This first half of the first truss span was supported at panel-points L5 by two shoe castings for one of the river towers. These castings rested upon the 58-in. wood plungers of the sand jacks shown in Fig. 5, these jacks resting upon the upper grillage. The lower grillage spanned the two 80-ft. girders. The temporary tower had concrete pedestals similar to those for the permanent towers. It spanned the line of the Northern Pacific R.R. along the river bank, and the bracing of the lower panels of its sides had to be designed to lie outside of the clearance limits for trains, as indicated in Fig. 4. It was 40x68 ft. at the base, and the diagonal bracing in the bottom panels was of 12x12-in. timbers.

This half span being in place, the traveler was erected upon it and finished the other half of the span as a cantilever. The permanent tower was then erected beneath the end of the span, and the trusses lowered upon it by means of the sand jacks. The plungers of these jacks, composed of 12x12-in. fir timbers, had crushed down more than was expected during the erection of the span, and there was barely ½ in. to spare in placing the shoes for the truss seats. The jacks were intended to provide 2-in. clearance, and designed for a load of 350 lb. per sq.in. on the sand.

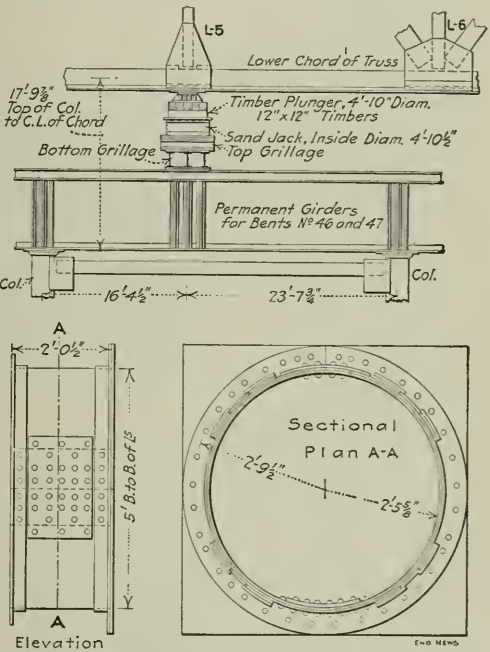

Fig. 5. Sand Jacks for Lowering the First Truss Span to Rest on Its Outer Tower

(The sand jacks were on the temporary tower, as shown in Fig. 4.)

The erecting device used to hold or anchor the cantilever for the other spans consisted of the usual compression members butting against the ends of the bottom chords and tension members pinned to the top chords of the previous span, as shown in Figs. 1 and 4. A wedge between two pins at the center of the tension members allowed the necessary adjustment for erection and for lowering the span upon the tower when completed. The wedge was operated by a screw by men standing on a platform slung below this temporary member. It was operated from beneath instead of from above in order to allow clearance for the traveler in passing over it.

The steel for the truss spans and the west approach was unloaded at the bridge site, and as required it was loaded upon car trucks or buggies and run out to the traveler by the dinky engine. The towers for the truss spans were erected complete under the spans before lowering the latter upon them. It was necessary to outhaul the lower columns, and this was done by means of a runner line at the end of a timber outrigger bolted to one end of the piers, as shown in Fig. 6. With over 200 ft. of drift this worked very well for the bottom section.

The middle sections [illegible] closer [illegible] and as there was [illegible] corresponding [illegible] the [illegible] of [illegible] the erection of both sections was [illegible].

Erection of the West Viaduct Approach

At the Ayer or west end of the bridge, the two 60-ft. girder spans and the first of the three 80-ft. spans were erected (starting at the shore end) by a derrick car with a [illegible] boom.

A special feature of the work was that the first bent of the tower for the 80-ft. span was assembled in an inclined position. This bent was 113 ft. high. It stood at an angle of about 60°, leaning against two timber bents fixed to the next tower. The lower end of one leg was in such position that it would engage the anchor bolts in the base plate when the bent was tipped into position. The other leg being about 6 ft. shorter (and the whole bent being on a 6° curve) was blocked up about 10 ft. in

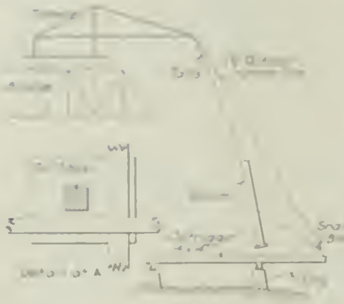

Fig. 6. [illegible] Columns [illegible] Tower of the [illegible] Span

from the pedestal and 6 in. higher than the tips of the anchor bolts; rails were placed under the base plates of the leg to [illegible] to slide it into place when tipped to the perpendicular position.

This placed the bent in a good position for tipping it into place and also brought the legs within the reach of the [illegible] boom of the derrick car. The two lower columns of the bent had to be [illegible], however. The position of this bent and the arrangements for its erection are shown in Fig. 7.

The [illegible] was [illegible] on the [illegible] the [illegible] and a [illegible] was [illegible] about [illegible] in one of the [illegible] and [illegible] on the [illegible] of the derrick car. The 113-ft. bent, weighing [illegible] tons [illegible], was then tipped to an upright position, the [illegible] fall line taking the load when the derrick-car falls had passed the length of the boom.

The bent was then moved and jacked into place, and lowered over the anchor bolts. This bent as erected had all of the transverse struts in place, but none of the bracing. The column splices and struts were 75% bolted.

The remaining two 80-ft. spans (which included the two 27-ton girders used on the temporary tower already

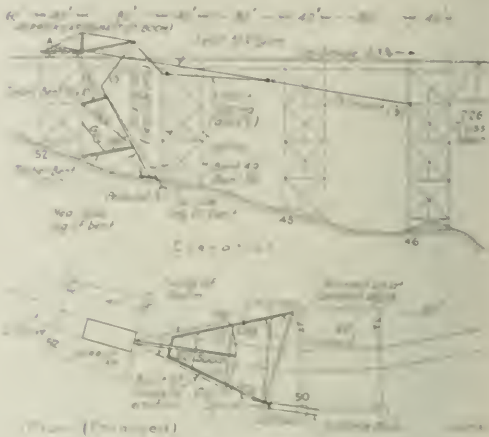

Fig. 7. Method of Erecting Bent No. 50 of the West Approach Viaduct

(The bent was assembled in the inclined position and then raised to its vertical position on the pedestals.)

described) were erected from the end of the truss spans of the bridge by means of the large derrick car which had erected these spans. One tower was also erected by this car. The car could not pass the 6° curve at this end of the bridge, and for this reason the smaller derrick car had to be used (working from the west) on the end girder spans.

The steel for the curved portion at the extreme west end of the bridge was [illegible] at the bridge yard and [illegible] to reach the west end for erection.

Engineers and Contractors

The design and construction of the bridge were under the direction of J. R. [illegible], Chief Engineer of the Oregon-Washington R.R. & Navigation Co., and [illegible] was [illegible] in charge. The steelwork was built by the American Bridge Co. ([illegible] plant). The Missouri Valley Bridge & Iron Works, of Leavenworth, Kan., had the contract for the piers and substructure. The Kelly-Atkinson Construction Co., of Chicago, had the contract for the steel erection, and its force [illegible] [illegible] men. The total weight of steel erected was about [illegible] tons.

Valuable Information on an Accident Report Blank [illegible]

Bridge Destruction in the European War

An army in retreat always endeavors to protect itself against the pursuing forces of the enemy by destroying the bridges in its rear, tearing up railroad tracks, burning rolling stock, etc. Some idea of the destruction effected in the zone of active military operations in Europe during the past three months is shown in the accompanying views.

It is a part of the duty of engineer troops in warfare to destroy the bridges in the rear as the army retreats, usually by exploding dynamite at the base of its piers, or, in case of masonry arches, at the haunch of the arch or the springing line. The duty of the engineer force with the pursuing army is to replace the gap as rapidly as possible by rapidly constructed pile or pontoon bridges. The photographs bring to mind the vast amount of new construction that will be required at the conclusion of the war to restore to normal conditions the avenues of transport and communication.

The Electric Precipitation of Tar Vapors from Gas

An interesting development of (or rather a departure from) the Cottrell process for the precipitation of suspended matter in gases (see ENGINEERING NEWS, Oct. 26, 1911, and Oct. 9, 1913) was described by F. W. Steere, of Detroit, before the American Gas Institute in New York, Oct. 22, 1914. The author, while engaged in research work at the University of Michigan upon the electrical separation of tar from gas, found that high-tension alternating current might be used instead of the rectified high-tension used by Cottrell. The gas to be purified is led through a pipe and the high-tension current discharged between a central electrode and the walls during passage. The gas is ionized and the resulting tendency to recombination of the dissociated atoms results in an agglomeration of the dense tar mist into relatively few and large tar drops. The larger tar particles can easily be freed after the gas has left the electrical chamber by passing through a centrifugal tar extractor, etc.

A plant having a capacity of about 30,000 cu.ft. of gas per hour was built at the Detroit coke ovens. Gas was taken from the hydraulic main, passed through a small washer cooler, and led through the ionizing tube from which it went to a spiral tar extractor and exhauster, a washer cooler and a Venturi meter leading to the main. In some 1200 tests, by aspirating a given quantity of gas through two thicknesses of filter paper, practically white papers were secured. All work was done on the rich gas given out during the first six or eight hours of the coking period of the recovery oven. Best results were obtained with gas entering the ionizer at from 65° to 80° C. It was found that the naphthalene crystals were freed after the tar was extracted, so that they were recovered clean and white.

With the aid of Edward Gray, Chief Engineer of the Ford Motor Co., a cleaning plant was built for the producer gas used in the large gas engines of this company. This plant has been in continuous and successful service for several months, has required no special attention, is self-cleaning, and is stopped and started by the regular employees.

Operation of Sand and Gravel Plants

By W. H. Wilms*

SYNOPSIS—A continuation of article in ENGINEERING NEWS, *Nov. 12, covering crushing, storage and power plant for sand and gravel plants.*

II.

PREPARATION OF SAND

GRADES—Two grades of sand are generally produced, a coarse sand for concrete and a fine sand for plastering and brickwork, often called building sand. The manner of preparation depends upon the character of the sand, the size and gradation of the bank-run material, and its specific gravity.

Coarse sand, or torpedo as it is called in the Middle West, is a sand ranging from 1/4 in. down to fine sand, the gradation being uniform. An analysis of a good grade of torpedo sand is given (Fig. 1).

SEPARATION OF GRADES—It is often the case that the sand contained in a gravel deposit is a well graduated, coarse sand and in such cases all that is necessary is to

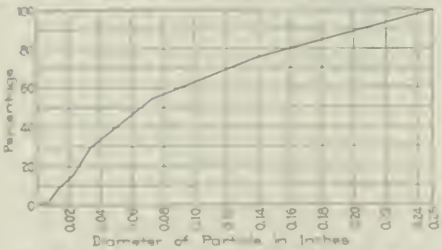

FIG. 1. ANALYSIS OF A GOOD TORPEDO SAND

screen it through a 1/4-in. or 3/8-in. screen (depending upon how coarse the sand is desired), and then take it directly to a settling tank to remove the dirt and water. In many instances, however, the bank sand is poorly graded, containing an excess of very fine sand, which must be removed before a well graded material can be obtained. This is done in several ways, depending upon the amount of the excess fine sand which must be taken out, the amount of water present, and the specific gravity of the sand.

Figs. 2, 3 and 4 show three methods commonly used to effect the removal of the fine sand. In Fig. 2 the sand coming through the perforations of the coarse sand screen is permitted to flow over a fine screen of about 1/4- to 1/8-in. mesh, which screens out any desired amount of the fine material by regulating the feed and the supply of clean water to the screen; an insufficient supply having a tendency to clog up the perforations, thus permitting a part of the fine material to pass over with the coarse.

In Fig. 3 the excess of fine sand is taken out by means of a second settling tank. This method works very well where the material has a comparatively low specific gravity and is [illegible]. Regulation here is obtained by raising or lowering the flashboard A in Fig. 3; by lowering this board the amount of fine sand flowing to the second settling tank is reduced, while raising it increases the amount of fine sand going over. A screen of small mesh is placed at the overflow of the final settling tank to prevent any large light particles from flowing over with the fine sand.

Fig. 4 illustrates a method now quite extensively used. The coarse and fine sand in flowing from the initial sand screen is made to pass over a small-mesh screen placed in the bottom of the trough or chute leading to the settling tank. Directly underneath this screen is a second tank. The screen takes out the fine material, separation of the dirt and water being effected by the settling tank directly underneath. Regulation is obtained by means of a sliding plate placed over the screen; this plate shortens or lengthens the length of the screen, thus regulating the amount of fine material going through.

SETTLING TANK—The settling tank is one of the most important parts of a washing and screening plant. A poor one will spoil material in the bins about as fast as it is prepared. While there are a number of patented sand separators on the market, the ordinary tilting settling tank (Fig. 5), when properly made and regulated will produce entirely satisfactory results.

The correct design of a settling tank for a given material can only be ascertained by trial. The proportions of length, width and depth of tank, the location and length of outlet pipe, the location of the supporting shaft and counterbalancing, all depend for their determination upon the nature of the sand, its weight and behavior in water, the amount of water and sand that the tank is required to take care of, and the uniformity of the flow of material to the tank.

For instance, the longer the discharge pipe, the dryer the sand coming from the tank. This is due, of course, to the greater and more effective seal formed by the longer pipe. There is a limit, however, at which the material will fail to discharge at all. Likewise, the shorter the pipe the wetter the sand discharged. Usually, however, a discharge pipe having a length equal to twice the diameter of the pipe will prove satisfactory. Six- and eight-inch pipes are commonly used.

With a given material and a uniform feed to the tank, a tank can be designed and constructed that will have a practically uniform discharge of material. The trouble experienced with poorly designed settling tanks is their constant tendency to let through the dirty water with the sand. It should be remembered, however, that no tank will operate satisfactorily if the flow of material to the tank is not uniform.

The settling tank is supported by a shaft having two bearings, upon which it has a slight rocking motion (see Fig. 5). The tank is counterbalanced at the rear with heavy weights. The valve opening in front is held against rubber-faced stops as a consequence.

The tank fills full of sand water, which runs off at the spillway at the top of the front. The sand quickly settles to the bottom of the tank, and when it accumulates enough weight it causes the tank to tip forward, drawing the opening in front of the tank away from the rubber-faced stops, the sand running through the opening.

When a sufficient amount of sand has escaped, the reduction of weight of sand in the tank causes the tank to

*[illegible], Portland Sand & Gravel Co., Portland, Ore.

draw back against the valve-stop, closing the opening and stopping the flow. If the material comes into the tank uniformly, the tank will remain in a state of equilibrium, the outflow equaling the inflow. Thus the tank action is continuous and automatic. The very fine undesirable sand is carried away with the waste water.

The supporting shafts of settling tanks should not have journal bearings, for the friction, though slight, is too great for the very sensitive action required in the operation of the tank. Instead, knife-edge bearings should always be used.

Operating Difficulties—More trouble is generally experienced with the operation of the fine-sand tank than with the coarse. It is often a very difficult matter to get this tank to discharge properly, the tendency being for most of the fine sand to remain in the tank, only that portion immediately over the valve opening

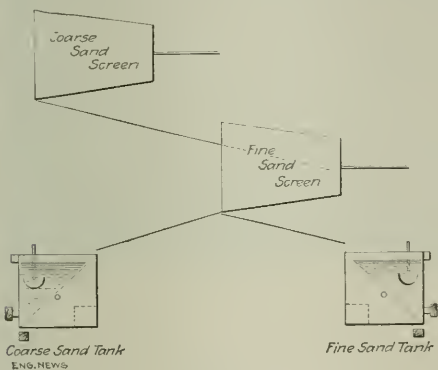

Fig. 2.

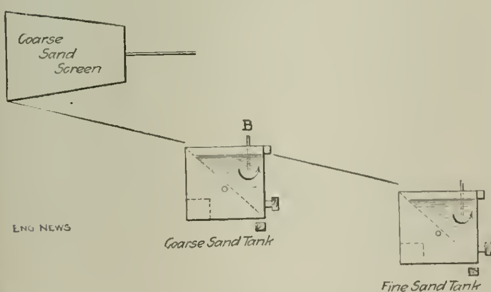

Fig. 3.

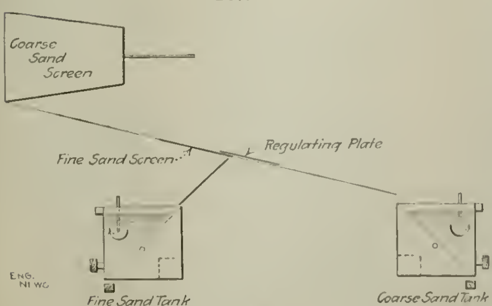

Fig. 4.

Figs. 2-4. Methods for Removing Fine Sand

being discharged. When this happens the tank will frequently "spill" or let through the dirty water. It only takes a very few of such "spills" to ruin an entire bin of sand.

This trouble can often be cured and the tank made to discharge itself completely by providing a small discharge opening with valve stop, similar to the main dis-

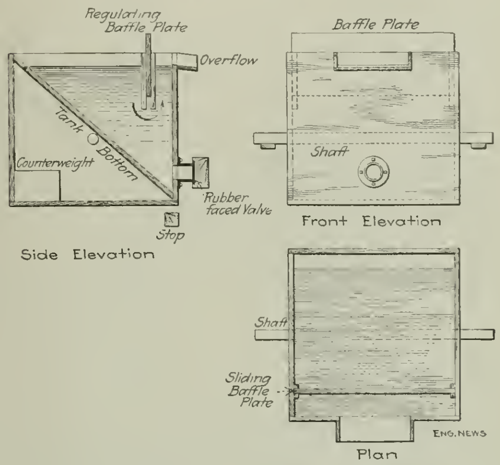

Fig. 5. Ordinary Tilting Settling Tank

charge, near each side of the tank and about one-third its depth from the bottom. This will keep the sand in these dead quarters more or less agitated and prevent it from settling and becoming compact.

Where the pit-run material is largely sand and the capacity of the plant a large one, some trouble is at times experienced with the automatic or tilting settling tank. Under such conditions a number of operators prefer stationary tanks, the discharge openings or valves being manually operated. Instead of one or two large openings, however, these tanks are provided with many small ones distributed around all four sides of the tank. The tank is made sufficiently large so as not to require the constant attendance of an operator, this work being usually performed by the man attending the "top."

Such tanks are usually made rectangular in shape instead of square as in the automatic or tilting tank, having a length of about twice the width and a depth of about one and one-half times the width. The valve openings are usually about 2 to 2½ in. in diameter.

A tank used especially in large ballast washing and screening plants is provided with conical discharge openings projecting from the bottom of the tank, the stop valves of these openings being operated from above by a small rack-and-pinion movement. These tanks are generally provided with two such openings, one being located near each end of the tank. The coarse sand is discharged from the opening near the head end of the tank and the fine sand from the other, separation being effected by the difference in the velocity of the water at the ends of the tank. While I have seen a fairly good sand produced by such a tank, the separation of the coarse from the fine sand is not as complete as it should be nor is the graduation everything to be desired.

Marketable Grades—In the preparation of a well

graded coarse sand, a large amount of fine building sand is often present. Not all producers are so fortunately situated as to have a large market for this fine material, and many plants are now wasting it (which is generally an excellent building sand) for the want of a market. Under such conditions the cost of production of a well graded coarse sand is materially increased.

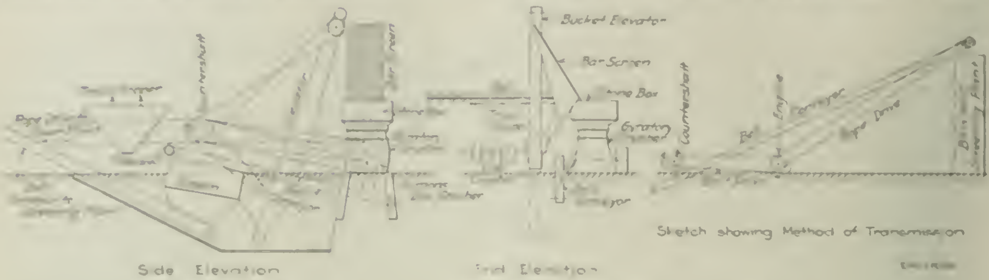

FIG. 6. DESIGN FOR INITIAL SCREENING BEFORE CRUSHING MATERIAL

It may be mentioned here that this question of a market for all grades of sand the plant produces is a vital one to the producer. Quite often it means just the difference between success or failure of the enterprise. The importance of a complete and accurate knowledge of the market requirements and a thorough test and examination of the deposit cannot be too strongly emphasized to those who are contemplating going into this industry.

CRUSHING EQUIPMENT

From the writer's observation and experience the main point of weakness of many screening and washing plants is in their crushing and reduction equipment. It is here that an otherwise satisfactory material falls short of attainment—insufficient reduction. The material often has but one reduction through a gyratory crusher, resulting in a large percentage of over-size material or rejections going into the finished product.

CRUSHING—To produce a uniformly graded material means fine reduction—much finer than the maximum size being produced in a given material. Even where the product from an initial gyratory crusher is screened and the rejections delivered to a smaller secondary gyratory crusher for final reduction, the results are not everything to be desired. In the writer's opinion, the only effective solution of this reduction problem is the installation of a Symons disc crusher for final reduction, the initial breaking being performed by a gyratory. A majority of the largest and best plants in the country are now performing their reduction in this manner.

LOCATION OF INITIAL SCREENS—The top of the screening plant being generally at least 60 ft. high, it follows that the initial screening of the over-size material and its reduction should, if possible, be effected before the material is elevated to the top of the plant for screening and washing. Placing the initial screen on top of the plant and dropping the over-size material to crushers on the ground below and then re-elevating the rejections, is certainly not a very efficient method, to say the least. And yet, with few exceptions, this is the general practice.

There are a few modern, up-to-date plants, however, that are performing this operation of initial screening and crushing before the material is elevated to the top of the plant. Fig. 6 shows the manner in which this is effected in two large western plants.

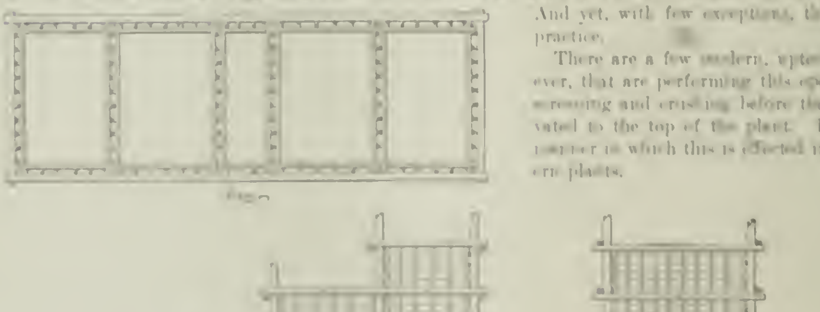

FIG. 7. BIN CONSTRUCTION BY THE MOST APPROVED METHODS

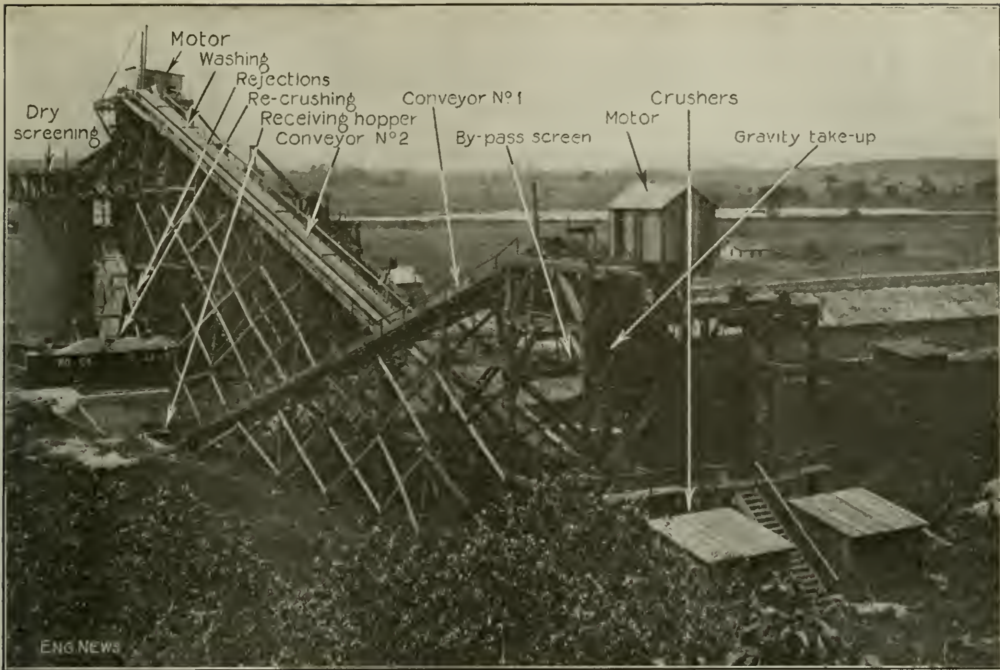

Fig. 8. Plant of the Chicago Sand & Gravel Co.

Elevating and Conveying

For elevating the material to the top of the plant the belt conveyor is almost universally regarded by operators as the best solution of the problem. Its slow and uniform feed to the screens, so necessary for effective screening, combined with large carrying capacity makes this method a very efficient one. While the initial cost and the cost of belt renewals exceeds that of a bucket elevator, the reduction in the amount of delays due to break-downs and repairs more than makes up for the difference.

In elevating the material to the top of the plant where the material is conveyed to the plant by cars discharging into a track hopper, the feasibility of using as heavy a grade as is practicable up to the hopper should be duly considered, thus reducing the height and length of the belt conveyor. Within certain limits it is more economical to elevate by cars and locomotive than by conveyor. Grades of tracks leading to the hopper, however, should not be excessive, 4% to 5% being considered a maximum.

Storage Bins

While storage bins are built of concrete and steel, the prevailing practice is to build them of timber. The bins are built up directly from the ground level, the space between the ground and bin gates being occupied by dead material; the wet material in the bins taking about a 40° slope (Fig. 7).

Construction—Bins of 14 to 20 ft. inside have proved to be the most economical under ordinary conditions. Greater widths than 20 ft. require extremely heavy cross-bracing and tying, making the construction an expensive one.

The old crib style of construction where the walls of the bin are built up of 2-in. plank laid and nailed together flatwise, has of late years given way to the form of construction shown in Fig. 7.

This design is not only somewhat more economical of lumber and labor of erection, but it possesses the additional advantage of easy and quick repairs. Repairs to bins built up of cribbing can be nothing more than patches. One of the main objections, however, to crib construction for sand and gravel bins is their extreme range of swelling and shrinkage in a vertical direction, due to the wet material in the bins. In a bin 35 to 45 ft. high this swelling and shrinkage often amounts to 5 or 6 in.

With the bearings carrying the screening and elevating machinery mounted directly on the top of such bins the results can better be imagined than described. In the frame type of construction the bearings are carried by an extension of the outside upright framing timbers which do not come in contact with the wet material.

Tunnel bins delivering material directly to cars underneath require extremely heavy masonry supports for the bin structure, and ordinarily are much more expensive for the same bin capacity than bins built directly upon the ground and filled up to the gate level with dead material.

Capacity—The capacity of bins necessary for a given daily yardage depends upon so many factors that no fixed rule can be given. The manner in which the plant is operated, extent and character of the switching facilities and service, the regularity in the supply of empty cars to the plant, whether or not open storage is practiced, all affect this question of bin capacity. Where there is a plentiful supply of empty cars but poor switching ser-

tion, it often pays to invest in a small switching locomotive rather than in additional bin capacity. Under ordinary circumstances, a bin capacity of from 450 to 600 cu.yd. is proper, even in the largest of plants.

LOADING FACILITIES.—In order to produce a gravel for roadways and concrete, containing a certain percentage of sand, it is necessary that at least one sand bin be adjacent to a gravel bin so that both the sand and gravel can feed out of the same spout into the car. If the sand and gravel are to be uniformly mixed, it must be effected while the materials are discharging into the car. In discharging sand and gravel already mixed in the bins, the gravel separates from the sand more or less, producing a very poor mix.

STORAGE—Closely connected with bin capacity is the question of open storage. It is here that practically every sand and gravel plant in the country is weak. The producer without provision for open storage is often compelled to sell his material at a loss, simply because he has no immediate market for it at the time it is produced. The demand for sand and gravel fluctuates more or less with activity in building and construction operations.

This wide range of fluctuation in demand causes the sand and gravel industry to operate under anything but favorable conditions, unless there is adequate provision

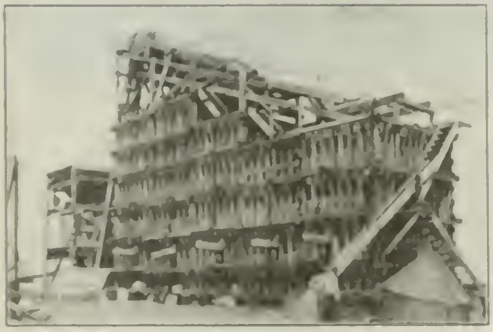

FIG. 9. PEORIA WASHED SAND & GRAVEL CO., PEORIA, ILL.

for large [illegible] storage—at very [illegible] as yet to the industry. The [illegible] situation, far from being perfect [illegible], helps to aggravate the condition. The increasing [illegible] of winter [illegible] is also becoming an important factor in the question of open storage, [illegible] being all that can be attempted during the [illegible] months and this only [illegible] great difficulty and increased cost of production.

POWER

There is no question of the economy of electric power for the operation of a screening and washing plant, where the same can be purchased at reasonable rates and without excessive primary charges. Due to the comparatively large number of units that must be driven and the comparatively great distances that often separate these units, the problem of transmission, where steam power is used, often becomes rather complicated and costly, both in first cost and maintenance. For these reasons, it often pays to use electric power with individual motor-driven units, even where the cost of same is somewhat above the ordinary.

Pertinent to this subject of electric power is the following from the report of the Committee on Electricity in Rural Districts, presented at the annual meeting of the National Electric Light Association, at Chicago, June [illegible], 1915:

Motor drive and central-station service have been thoroughly tried out in this industry (sand and gravel). The flexibility of motor drive is of great value here. Putting individual motors on distant pumps and cutting belts dispenses with the operating troubles from long shafts, belts and long rope drives. On account of pumps being of considerable size and located several hundred feet from the screening plant, the use of [illegible] motors will in general be found desirable.

The sand and gravel season comes as soon as the ground is frozen and [illegible] shut down at [illegible] so that the load is strictly "off peak." Some attempt has been made to do dry screening in winter but with small success.

A combination of individual and group drive will be found most advantageous in crusher plants, and the use of [illegible] motors will generally prove best. Crushers should be driven by slip-ring motors. If a crusher is shut down when it is full of rock it is often a troublesome job to clear it of all rock before starting up again. This is especially true if the crusher is driven by a squirrel-cage motor. If a slip-ring motor is used and the [illegible] belt is [illegible] up a few feet at a time the motor will often be able to start the crusher without its being necessary to clean out the rock. Dust-proof motors should be used on all stone-plant motors, and it will usually pay to install all wiring in conduit.*

Steam power, however, will generally be the only form of power available to sand and gravel plants for a long time to come. The main problem here is to so concentrate the various units as to reduce the number of belt and rope drives and shafting to a minimum. Any method or means by which a belt, rope drive, shaft or gear can be eliminated is well worthy of consideration, for it is in the transmission that break-downs, delays, grief and trouble occur with too great a frequency for the peace of mind of the operator. Fig. 6 shows to what extent this problem of transmission has been solved in one particular case.

As a rule, the power-house equipment should be chosen for simplicity and rough handling rather than for economy and should consist of a plain slide valve or simple automatic engine, tubular boilers, heater, feed pump, etc. High-duty engines, water-tube boilers, and condensers have been installed, however, and this practice will undoubtedly be followed more and more as the industry develops.

Tests of Pipe Coatings as a Preventive of Electrolysis

Tests of "waterproof" coatings of iron and steel pipe have been made by the U. S. Bureau of Standards as a part of its broad investigations of the electrolysis problem and a report on the results has been issued as a bulletin (No. [illegible]) by Burton McCollum and O. S. Peters. The materials which were used as surface coatings are as follows: (1) Paints which may be applied at ordinary temperatures and depend on oxidation, chemical action, or drying for setting; (2) dips intended to be fixed at high temperatures—including asphalt, coal-tar, pitches, etc.; (3) wrappings consisting of alternate layers of cloth or paper and paints or dips; (4) fiber conduits in which the pipes can be laid with or without pitch filling; (5) vitreous enamels; (6) portland-cement mortar and concrete coatings.

The last has been dismissed from further considera-

*The abstract of this report in "Engineering News," June [illegible], 1915, p. [illegible].

ation by the Bureau, after calling attention to the fact that portland-cement mortar absorbs water readily and becomes a conductor of electricity at all times in damp soils. When the concrete is new, however, and contains much calcium hydroxide, there is an appreciable passivating action which allows current to leave a coated pipe without much corrosion of the iron; but, as the calcium hydroxide becomes converted to carbonate, this property is lost and the pipe corrodes rapidly.

The insulating properties of fiber conduits and vitreous enamels are still being investigated, and have not yet been reported on.

For studying the action of the paints, sheet-iron cones of about 7-in. base diameter and 1¾-in. altitude were used, coated on the interior. Four coats were usually found sufficient to give the best results of which any paint was capable, precaution being taken to secure perfect films.

The first test to which the painted specimens were subjected after the paint had dried was one for pinholes and flaws. The cone was filled with salt solution and 80 volts 60-cycle alternating potential applied for 30 sec. If no deflection of the galvanometer needle occurred, the coating was considered perfect. Specimens failing this test were rejected until a set of five perfect specimens was obtained for each paint. The effects of length of drying period were evident; the percentage of defective coatings tested at the end of ten days' drying was four or five times as great as at the end of two months' drying.

In the final test, each cone was filled to ½ in. from the rim with tap water or some electrolyte and placed in a rack. Two cones from each set of five were connected up with the sheet iron as anode and a bare copper wire, dipping into the water, as cathode. A third cone was connected in reverse order. A constant potential of four volts was impressed on the circuit leading to the paint films. Once in about two weeks the water would be completely evaporated from the cones and they would be refilled. This was desirable, to give alternate wetting and air exposure. The first appearance of current flow across the paint film was noted as failure, but the specimens were left in circuit until rupture was complete. There were 32 different paints, covering most of the widely advertised compounds, though not all (no so called "Bitumastic" products).

The general results showed that none was to be heavily relied upon to preserve its insulating barrier. Some lasted only a few hours, others a few thousand. Here and there, certain individual specimens withstood the action longer than others, even of their own makes. In one particular case ("Carbonkote" Interior) only one of the four specimens failed in a year of exposure. The data for each specimen indicate that the voltage had no appreciable effect toward reducing the length of service, which seems to depend upon the properties of the individual samples and the action of the water. However, the manner of failure of the coatings was distinctive of the direction of flow. Where the current was from iron to water, little rust spots appeared which grew to craters or bubbles; removal of a crater bubble revealed a pit filled with rust. Where the flow was from water to iron, no rusting of iron occurred, but gas was liberated under the film and lifted the latter until a blister was formed which left a large area of iron unprotected. Specimens to which no voltage had been applied showed no deterioration visible to the eye, in most cases, though they would permit current to flow.

Tests of fibrous pipe wrapping were carried out in much the same way. Sheet-iron cones were used, lined with alternate layers of dip or paint and paper or fabric. Four specimens were made for each test. These were set up in a rack, as previously described and filled with tap water. Two were set up with the iron positive, and two with the iron negative; a potential of 15 volts was employed. A few cones which were merely dipped were subjected to only four volts. There were 33 samples employing some 14 different compounds with various combinations of wrappings. At the time the report was made 82% of the total specimens had failed in periods varying from 7000 to 14,000 hours. On the remaining cones, the tests were still incomplete.

The results do not indicate that a life of such coatings as an insulating barrier can be expected to be more than two or three years and, in most of the cases, failure may be expected within a few months. The manner of failure was very similar to those of the paint coatings. The rupture of the coatings, however, was slower than with the paint after the first appearance of electrical breakdown—probably due to the thickness and rigidity of the coatings.

To avoid criticisms that the studies did not reproduce practical conditions, 26 specimens of wrapped pipe were buried in earth and connected to the positive side of a 15-volt direct-current circuit, so that the pipe had a potential of about 4.5 volts about the surrounding earth. The ground was quite wet during the spring and fairly moist during the rest of the year. Twenty-four of these specimens were furnished by commercial firms; 12 consisted of 5-ft. lengths of 4-in. wrought-iron pipe wrapped with two alternate layers of pitch and burlap. The other 12 were 5-ft. lengths of 1½-in. wrought-iron pipe covered with four alternate layers of tar and paper. The wrapping was not impregnated and apparently consisted of heavy paper wound spirally over the hot coat of tar, the latter containing 3 or 4% lime (Nichols coating). The electrical connections were soldered on the inside of the pipe, the ends closed with wooden plugs, and capped with several thicknesses of tar paper and pitch. Two specimens of wrapped pipe were made up by the Bureau, each having three coats of insulating paint and two layers of muslin painted on. The pitch-and-burlap specimens failed in from seven to 56 days; the tar-and-paper-wrapped specimens failed in 29 days for the most part, although one lasted 75 days and one failed in two. The paint-and-muslin samples broke down after 36 days. The pipes were left in the ground under test from 10 to 18 months. When they were removed and the wrappings stripped off, they were found to be covered with rough spots and were pitted to considerable depths.

The Bureau concludes that paints, dips and wrappings have little value for protecting pipes from electrolysis. The failure of the coatings they explain by the absorption of moisture which was found when any of the coatings were carefully weighed before and after immersion. These studies, the Bureau cautions, throw no light on the value of these coatings for protecting the various mains from natural soil corrosion, as there is considerable practical evidence that they have a certain protection where no electrical effects are involved.

A Century Rainfall Record at New Bedford, Mass.*

By X. H. Goodnough†

SYNOPSIS—A continuous rainfall record kept by father and son for 92 consecutive years is here rounded out from other records in the same city to a full century. By years the rainfall ranged from [illegible] to [illegible], with an average of [illegible] in. By months, the range was from [illegible] in June, 1912, to 18.72 in. in August, [illegible]. The record shows no progressive change in annual rainfall, but does indicate that for periods of [illegible] to 12 years the annual rainfall continues at a high rate or a low rate. Of six periods of low rainfall within the century, [illegible] has occurred during its last half, and one of these began in 1908. This suggests the possibility that we are now in a period of lower rainfall and stream flow. [illegible]

Among the most valuable of rainfall observations in New England are those begun at New Bedford by Samuel Rodman in 1814, and continued by him until his death on Aug. 1, 1876, and afterward continued by his son Thomas R. Rodman, until he died on Dec. 1, 1905, thus giving a continuous record by these two observers for 92 years. By using the observations at other stations in New Bedford, of which there are several, it is now possible to present a continuous record of rainfall observations at practically the same point for one hundred years.

The rain gage used by the Rodmans was located in the western part of a thickly settled portion of the city upon a ridge about half a mile west of the shore of New Bedford harbor and at an elevation of about [illegible] ft. above mean sea level. The gage was placed near the ground in a large open area where the conditions were favorable for accurate observation. The records are believed to be wholly reliable.

Since 1905 various observations are available, including those made with a gage located on the roof of the city hall, [illegible] Rodman residence, at an elevation of about [illegible] ft. above mean sea level, and those made by Charles H. Adams at a point a short distance north of the Rodman residence and also at an elevation of about [illegible] ft. above the sea. The city hall observations have been [illegible] they were interrupted by the [illegible] of the city hall in 190[illegible], and no observations were made in the years 1907 to 1908. Observations are also made by L. J. Hathaway, Jr., of the New Bedford Engineering Department, at a point about [illegible] miles north of the Rodman gage. These observations are made with a standard gage in an excellent location near the ground at an elevation about [illegible] ft. above the sea.

The monthly, annual and average precipitation for the years 1814 to 1913 is given in Table I. The table has been made up by using the Rodman records from 1814 to 1905, the observations of Charles H. Adams for 1906 and 1907, and the observations of L. J. Hathaway, Jr., [illegible]

from 1908 to 1913. If observations at other stations had been used for the period since 1905, the difference in the results given in the table would not be important.

For convenience in the study of these records, Table II is presented, showing the extremes of precipitation in each month and year, arranged in order from the minimum to the maximum amount.

The average annual rainfall at New Bedford, as shown by these records, during this period of 100 years, was 46.45 in. The driest year was 1846, with a rainfall of 34.51 in., and the wettest, 1829, with a rainfall of 65.41 in. The driest month was June, 1912, with a precipitation of 0.10 in. The wettest month was August, 1826, with a total precipitation of 18.72 in. It is interesting to note that it was also in the month of August, 1826, that the Willey family was overwhelmed by an avalanche in the Crawford Notch [White Mountains, in New Hampshire], attributed to the excessive rainfall.

The diagram, Fig. 1, shows the variation year by year in the annual rainfall and also the years when the precipitation was less than or greater than the average.

One of the chief values of continuous observation of rainfall covering a very long period at the same place is the evidence that such a record may give as to a progressive change in the amount of annual precipitation. No indication of such a change is shown by these records. A study of the diagram and tables indicates that periods of several years of continuous high or low or average rainfall succeed each other and that these periods have generally averaged, in this instance, eight or ten years in length (see Table III).

TABLE III—TABLE SHOWING GROUPS OF DRY, WET AND AVERAGE YEARS AT NEW BEDFORD

Period	Number of years	Average rainfall per year
1814-1822	9	42.28
1823-1832	10	54.26
1833-1839	7	42.79
1840-1843	4	47.48
1844-1849	6	41.06
1850-1854	5	50.74
1855-1866	12	43.23
1867-1878	12	48.91
1879-1885	7	42.59
1886-1890	5	51.22
1891-1895	5	45.69
1896-1904	9	49.34
1905-1912	8	42.54

The variations in the annual rainfall are, however, shown perhaps more satisfactorily by the diagram, Fig. 2, which shows the three-year progressive averages of the rainfall in this 100-year period. This diagram shows that there have been six periods of very low rainfall at New Bedford since 1814, or an average of one in about 17 years. There was about an equal number of periods of average or high rainfall, the maximum rainfall occurring in the years about 1830, when the precipitation was much greater than at any subsequent time, the nearest approach to it being the period of a few years about 1890.

This diagram is interesting as showing that of the six

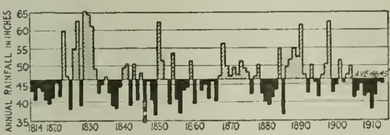

FIG. 1.

(Annual rainfall at New Bedford, Mass., for the 100 years 1814 to 1913 and the excess or deficiency for each year as compared with the average for the century.)

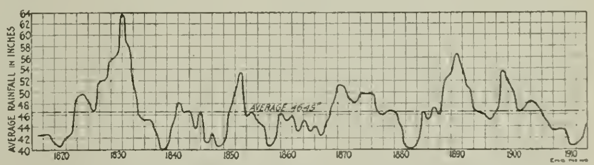

FIG. 2

(Three-year progressive average rainfalls at New Bedford, Mass., 1814 to 1913, plotted on third years.)

periods of very low rainfall at New Bedford only two have occurred in the last fifty years, namely, the period from 1880 to 1883, and the period from 1908 to 1911.

So far as these observations show, there is no indication of variations covering periods longer than about 17 years, but studies of other observations in New England indicate quite clearly that the rainfall for at least 35 years preceding the year 1850, and possibly for a much longer period, was, except for the years about 1830, very much less than the average; while the rainfall from 1850 to about 1903, except for a few years about 1883, was nearly always greater than the average. Since 1903 the rainfall in most parts of New England has averaged much less than the normal amount.

The New Bedford records agree in general with those of other long-continued observations in New England, except that they show as a rule somewhat less rainfall in some of the years between 1849 and 1879, especially in years between 1850 and 1860, than are shown by records of rainfall in this period at stations farther west and north.

The average monthly rainfall at New Bedford during the entire period of 100 years is shown graphically by Fig. 3, a glance at which will show that the month of least rainfall is June, when the quantity has been but little in

amount of 7 in., followed by July, with a rainfall of about 4.5 in. The minimum rainfall has occurred in March, closely followed by November, but there is also a high rainfall in the month of August, the quantity being much greater than in the other summer months.

A study of the seasonal distribution of the rainfall is

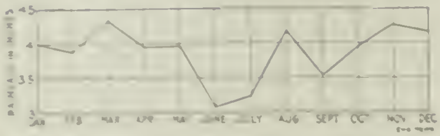

FIG. 3. MONTHLY RAINFALL AVERAGES AT NEW BEDFORD, MASS., 1814 TO 1913

interesting. The average rainfall for the months of December, January and February, taking in each case consecutive months, shows no material variation in the amount of the winter precipitation throughout this long period. The minimum winter rainfall ever recorded occurred apparently in the year of 1838-1839, when the average precipitation per month was 1.48 in. Next in order comes the winter of 1818-1819, with an average precipitation of 2.03 in. per month, and then 1901 with a monthly precipitation of 2.20 in. Next in order come 1876, 1903, 1872, 1890 and 1820, in all of which the precipitation averaged less than 2.75 in. per month. The maximum winter rainfall occurred in 1891, when the average precipitation was 6.95 in. per month. Next in order comes the year 1896 with 6.37 in. per month, then 1887 with 6.35 in., 1824 with 6.30 in., and 1902 with 6.07 in., these being all of the winters in which the rainfall exceeded 6 in. per month.

A study of the rainfall in the spring months, March, April and May, shows that the maximum amount occurred in 1901, when the average monthly precipitation was 7.83 in. Then follow 1890 with 6.90 in. and 1829 with 6.80 in. The minimum monthly precipitation in this period occurred in 1817, and amounted to 1.85 in. per month. Next in order comes 1866 with a monthly precipitation of 2.05 and then 1910 with 2.24 in. Low spring rainfalls were very much more common in the first 50 years of the observations at New Bedford, that is from 1814 to 1863, than they have been in the last 50 years. In the first 50 years the period of spring rainfall averaged less than 3 in. per month in 13 of the 50 years, viz., 1817, [illegible], [illegible], 1833, 1836, 1839, 1849, 1847, [illegible], while in the last 50 years the spring rainfall has fallen below 3 in. only in the years 1881, 1883, 1895, 1905, 1910 and 1911.

The average rainfall in the summer months, June, July and August, was highest in 1826, when it amounted to 7.76 in. per month, due to the great rainfall in the month of August of that year. Next in order comes 1820 with an average monthly precipitation of 7.01, then 1864 with 6.94 in. Except in these years, the average monthly precipitation in summer has exceeded 6 in. only four times. The minimum summer precipitation occurred in 1825, when the average monthly quantity was 1.27 in. Then comes in order 1881 with 1.37 in., 1883 with 1.38 in. per month, 1876 with 1.45 in., and 1907 with 1.61 in. There were three other years, viz., 1841, 1899 and 1876, when the average summer precipitation was less than 2 in. A summer precipitation averaging less than 2 in. per month occurred but once in the first 50 years of these observations and has occurred seven times within the last 40 years.

In the autumn months, September, October and November, the minimum precipitation throughout this period occurred in 1837, when the average quantity was 1.13 in. per month, by far the lowest recorded in the 100 years. Next to 1837, the driest autumn was in 1842, when the quantity amounted to 1.97 in. Besides these years the average monthly rainfall in the autumn has been less than 3 in. in 20 years of the period.

So far as can be judged, these observations seem to indicate on the whole that the rainfall of the spring months has been higher, as a rule, in the last 50 years than in the earlier half of the period covered by these observations, while the frequency of intense summer droughts has been greater in recent years than in the earlier half of the period covered by the observations. These differences are not of great importance, however, and with a different grouping of the months they largely disappear.

The chief result shown by a study of this record of 100 years, which is confirmed by other observations in New England, is that years and periods of years occurred in the early part of the 19th century, in which the precipitation was either lower than in any similar period of recent years or was so distributed as to be likely to produce a much lower flow in the streams than in any similar periods in recent times. They indicate the necessity of making allowance in calculations of yield of water-sheds for the occurrence of drier periods than those which have ordinarily hitherto been regarded as the driest which are likely to be experienced. If there is a variation in the rainfall covering long periods of fifty years or more, it is possible that we are entering now a period which will contain years of much lower stream flow than any that have occurred since the middle of the 19th century.

State Supervision of Engineering Work in Pennsylvania

We published in our issue of Oct. 29 (p. 870) the report of a committee of the Association of Philadelphia Members of the American Society of Civil Engineers relative to the proposed law requiring engineers practicing in the State of Pennsylvania to be examined and licensed. At a meeting of the association on Oct. 26, the committee presented a supplementary report in which it was recommended that the state should supervise the carrying out of engineering work to safeguard the interests of the public. This is in effect a continuation of the established policy of the state to supervise the construction of dams and reservoirs, a policy entered upon after the failure of the Austin dam in 1911.

We print the substance of this report as follows:

In our original report the committee recommended the creation of a state engineering department . . . [illegible] . . . It is of fundamental importance that the state should [illegible] its responsibility for safeguarding the interests of the public in connection with engineering work.

[illegible]

[illegible]

employed are held to little or no direct responsibility under the law. These conditions hold out no assurance of professional competency and integrity on the part of engineers thus employed, for duties in connection with which incompetency is likely to result not only in the waste of public funds, but in the jeopardy of human life, health and safety. The existence of these conditions is discreditable to the State of Pennsylvania, and it is earnestly recommended that adequate remedial state measures be promptly enacted.

In general it is desirable that the employment, retention or discharge of engineers in public service should be governed by the same principles as under private corporate management. The following suggestions are offered as indicative in a general way of the requirements of the situation, without aiming at completeness or the best means of adapting them to existing conditions:

1. **Civil Service Examinations:** It is highly desirable that the appointment of engineers and technical men in general, with duties of a nature in which competency may be readily determined by examination, should be subject to state or municipal civil service regulation. In cities of the first and second class, such civil service examinations may properly be conducted under independent management. For other municipalities, counties and boroughs it is desirable that such civil service examinations be conducted by a state department, in order that these examinations may be governed by reasonable and consistent standards, and that a single body may be charged with the enforcement of such standards.

2. **Exemptions from Civil Service Examinations:** It is desirable that appointments to engineering or technical positions above a certain rank should not be governed by competitive civil service examinations, but that the appointees should be chosen on the basis of their professional record. It is desirable that such appointments should be made either by the state civil service examination department direct, or at the initiative of designated state officers, but with its approval.

3. **Other Functions of the State Civil Service Examination Department:**

(a) It is desirable that the state civil service examination department should be authorized to investigate charges of incompetency or official dereliction on the part of engineers and other technical men appointed through civil service, except employees of cities of the first and second class, and that it alone should be empowered to disqualify such public servants, and only for adequate cause.

(b) It is further desirable that the state civil service examination department should act in an advisory capacity in connection with the employment of consulting engineers or experts for special temporary engagements, and that no engagements of that character should be legal without its approval.

This plan would tend to prevent the engagement through ignorance, or from interested or political motives, of incompetent or unscrupulous engineers and technical men and would likewise tend to facilitate the approval of plans for public works on the part of the several state departments concerned. It would also serve to minimize abuse under the system by which nominally free engineering services are rendered by commercial concerns, and by which patented schemes and devices of questionable merit, or of unnecessary cost, are prescribed in specifications for public works. Finally, it should serve as an effective check upon the prevailing method by which professional engagements are made a matter of competitive bidding. This system, which cannot be too strongly condemned, places a premium on incompetency and unscrupulousness at the expense of public interests. Experienced, able and reputable engineers refrain from participating in such competitions and would, in fact, have little or no chance of obtaining a commission under its operation.

(c) It should be one of the duties of the state civil service examination department to educate public and official sentiment as to methods of procedure in the employment of competent engineers and other technical men, and as to the danger to public interests through the engagement of incompetent men from mistaken motives of economy or other reasons.

In conclusion the committee recommends the creation of a state department of public works which shall be in charge of the administration of the above proposed (1) civil service examination system and (2) supervisory system of plans and inspection of engineering works, and in which shall be centralized such other matters relating to public engineering activities as may seem proper.

The principles embodied in the above report were approved by the Association of Members of the American Society of Civil Engineers at its meeting on Oct. 26 and by the Engineers' Club of Philadelphia at its meeting on Oct. 27.

A Double Loop on a Mountain Railway

The corkscrew loop shown in the view on this page is the Cimbatti Loop on the narrow-gage railway leading up to the hill station at Darjeeling, in Bengal, at the foothills of the Himalayas. This line begins at a point a short distance north of the Ganges River, which is reached from Calcutta by a standard-gage road, and continues on heavy grade to make the 7000-ft. rise to Darjeeling. At the loop shown, the track makes two complete circles each of a radius a little over 100 ft. Such construction is fairly common in the Luna Parks or other amusement parks of this country, but hardly to be expected on a regular passenger- and freight-carrying line.

THE CIMBATTI LOOP ON THE DARJEELING-CALCUTTA RAILWAY, INDIA

Slate Creek Bridge: Building a Concrete Arch Bridge 56 Mi. from Rail

By Jean H. Knox*

The first reinforced-concrete bridge in the Sierra Nevada Mountains of California was completed in October, 1913, spanning Slate Creek on the boundary line between Plumas and Sierra Counties.

In the spring of last year it was found that the Slate Creek bridge, although constructed only eight years, was in a state of ill repair and unsafe for further traffic. This structure, a 72-ft. combination wood-and-steel truss bridge, supported by concrete and steel cylinders, was the fifth bridge to be constructed at this crossing since the early fifties.

For years the people had accepted as fact the statement that the first cost of a reinforced-concrete bridge in a rough mountainous country, isolated from a railroad, was prohibitive, as compared with a wooden or a steel structure. The county engineer of Plumas County and the [illegible] decided to make a test case of comparative bids for various types of bridges. The lowest bid received for the construction of a steel bridge with wood floor and concrete abutments was [illegible], and the lowest bid for a reinforced-concrete bridge was [illegible]. The latter bid was accepted.

A brief description will serve to illustrate the [illegible] of the [illegible] bridge. The structure is a [illegible] rib arch. It was designed for a uniform live load of [illegible] lb. per sq.ft. or a [illegible]-ton roller. With an assumed ratio of moduli of [illegible], the allowed stresses were [illegible] lb. compression and [illegible] lb. shear in the concrete, and [illegible] lb. tension in the steel.

The principal features of the structure are shown in the drawing, Fig. 3. [illegible]

Columns rising from the arch-ribs support transverse floor beams, which cantilever 3 ft. out beyond either column; they were designed as T-beams. The floor of the bridge was designed as a succession of arched longitudinal T-beams running continuous over supports. Expansion joints are located over the hinges at crown and haunches. The columns and floor of the approach spans are similar to those of the arch span.

Ornamental balustrades extend the length of the bridge on either curb line. A blanket wearing surface ½ in. to 1 in. thick, composed of fine, dry gravel and asphaltum road oil, covers the surface of the roadway.

Fig. 1. Old and New Bridges

Fig. 2. East Abutment; Cantilever Type

(Slate Creek arch bridge in the Sierras 56 miles from rail, cheaper than a steel bridge.)

Standard specifications governed the kind and quality of all materials used in construction.

Conditions at Site Governing Construction

The bridge is located between La Porte in Plumas County, and St. Louis in Sierra County. The site is about [illegible] mi. south of Quincy, the county seat of Plumas County, and 56 mi. east of Oroville, in Butte County. [illegible] so all equipment and materials were shipped by rail to the latter town and freighted by six-horse teams to the bridge site. [illegible] The cost of hauling amounted to nearly [illegible] of the total contract price.

Slate Creek, in the vicinity of the bridge, flows through a deep, [illegible] rocky canyon, and the road crossing is located near the [illegible] of a bend in the creek. In the early days of mining, a tunnel was driven, [illegible] and the bed of the stream at the bridge site is practically dry.

[illegible]

*[illegible]

and carried away by scouring, till at this point there was left a clean bank of gravel 25 ft. high by 25 ft. wide near one end of the bridge site. The convenient location and excellent quality of this gravel made the problem of securing concrete aggregate a simple one. The gravel varied from well graded sand to 2-in. round gravel. The sand content was found by screening to be about equal to the coarse aggregate retained on a ¼-in. screen. The sand content was determined from time to time as the work progressed, enough screened coarse aggregate being added to make the proper proportions.

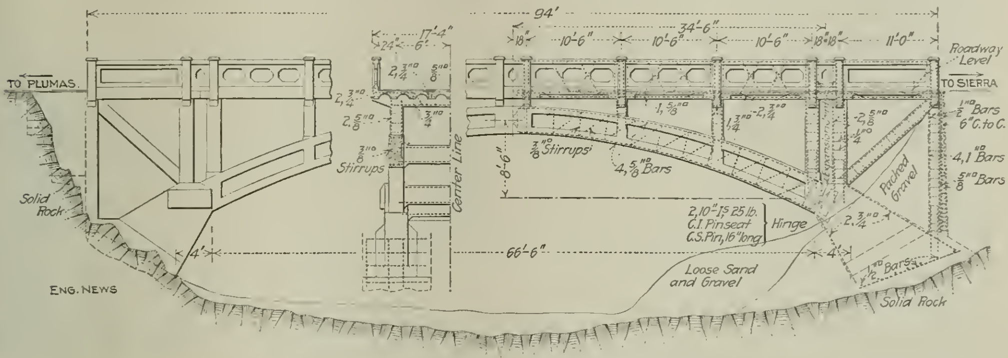

Fig. 3. Design Details of Slate Creek Bridge

Forms: Concreting

The concrete was mixed by hand. For concreting the abutments the mixing platform was placed on the side of the gravel bank, near the north abutment, and at a height that permitted the placing of most of the concrete for this abutment with chutes. Concrete buggies and wheelbarrows were used for placing concrete in the south abutment. Then the concrete for the short approach span over the north abutment was placed, and the mixing platform was then located on this portion of the completed floor. From this location the arch-ribs were poured and all that portion of the superstructure on the north side. The mixing platform was moved ahead on the floor as rapidly as completed, the concrete being shoveled directly into the forms or placed by means of metal chutes. These chutes were made from the rolled-metal forms which were used for the arched-floor system.

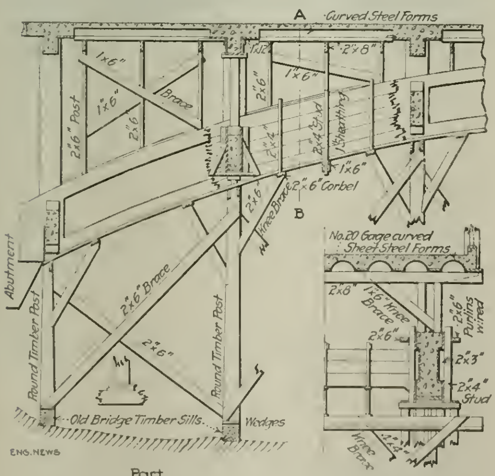

Fig. 4. Falsework and Forms for Slate Creek Bridge

Fig. 4 shows the form construction. Lumber for forms and falsework was hauled from a mill located about 20 mi. distant from the bridge. About 6 M ft. of sawed lumber was used. Round poles cut near the vicinity of the work were used for centering and falsework posts.

The arch-rib forms were supported by vertical posts at points just below the spandrel columns, 10½ ft. apart. The posts were connected at the top by two transverse 2x6-in. ledgers housed into the posts and bolted, and were further braced in two directions with 2x6-in. pieces. The soffit of the arch-ribs was formed with 1½x18-in. lumber bent to the true arch curve and held in position by knee-bracing to the posts.

Side forms for arch-ribs on the north half of bridge were made in sections, jointed at the spandrel columns, and, with the brace-beam forms, were used again for the south half. Forms for the spandrel columns and transverse floor-beams were also used twice.

The small arches in the floor were formed by using curved sheet steel of 20 gage, which was held at the corners of the 2x8-in. piece which formed the stem of the longitudinal T-beams, by 6d. nails. These curved steel forms were removed in from three to four days and were used four times. The forms for each floor panel were supported by three 2x8 joists 18 ft. long, resting on 2x6 posts, which in turn rested on the arch-ribs.

The railing panels, 10 ft. long, 2½ ft. high and 2½ in. thick, were cast two at a time on a level platform at one end of the bridge. After curing sufficiently, they were placed in position in the bridge curbs, framing into the forms for top rail and posts, which were then poured in place. Forms for one-fourth of total railing were framed, then used four times.

For the roadway wearing surface, the hot asphaltum oil was first applied directly on the concrete slab, using ½ gal. per sq.yd.; then the gravel was spread over the area and rolled to a smooth, compact surface. The roller was made by casting concrete in a form about 2 ft. wide and

2½ ft. in diameter, [illegible] through the center for [illegible] axle and [illegible] shafts.

LABOR, MATERIALS AND COSTS

Excepting the time used for removal of falsework and the old combination bridge adjacent to the site, the work was completed in 62 working days.

The working force consisted of one foreman, and 8 to 10 men, the majority of whom were common laborers who lived in the vicinity of the work. The men were willing workers but unskilled in concrete construction. The common wage was $3 for an 8-hr. day.

Materials in the bridge amounted to 60 cu.yd. of 1:3:5 concrete in the substructure, and 93 cu.yd. of 1:2:4 concrete in the superstructure, and 14,000 lb. of reinforcing steel. The structural and cast-metal hinges had a total weight of about 1800 lb.

The contract price for the bridge was $5540, and $170.80 was allowed for extra earthwork and raising the old combination bridge. The total cost of the bridge per square foot of floor area was $2.44.

Including superintendence, the following unit labor costs were deduced:

Bending and placing reinforcing steel	$0.012 per lb.
Mixing and placing concrete	2.14 per cu.yd.
Designing and falsework, including striking and removal	[illegible] per M ft.
Forms and cost of stripping	[illegible] per M ft.
	[illegible] per cu.yd.
Railing, in place	1.[illegible] per lin.ft.

The Slate Creek bridge was constructed and paid for jointly by the Counties of Plumas and Sierra, but the work was contracted for and directed by Plumas County. B. F. Barker is surveyor for Plumas County and was directly in charge of the work for the county. The [illegible] Engineering Co., Inc., of Oakland, were the designing and consulting engineers. [illegible] & Tibbetts, of San Francisco, were the contractors. L. R. [illegible] was resident engineer. D. M. McPhetres, who furnished the cost data and pictures for this article, was in charge of the work for the contractors.

Three-Stage Air Compressor for 2500-Lb. Pressure

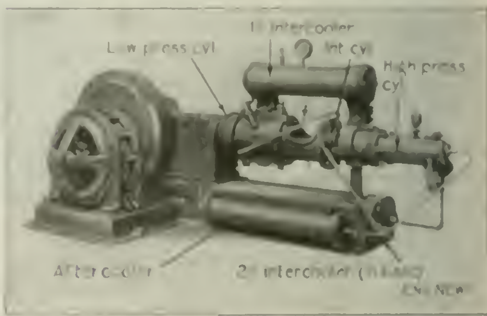
Air compressors with a terminal pressure of 2500 lb. per sq.in. have been built recently for the U. S. Navy Department, for use in the testing of torpedoes. They are of the horizontal type, with an electric motor geared to the compressor crankshaft. The [illegible] is on the [illegible], the crank [illegible]. The [illegible] cylinders are 7, 4½ and 1¾ in. in diameter and have a 10-in. stroke. The delivery capacity is 20 cu.ft. per hr. at 2500 lb. pressure, with a speed of [illegible] r.p.m., and absorb 30 hp. at the crankshaft.

The low-pressure cylinder is double-acting, is water-jacketed on the barrel and ends, and has vertical poppet valves. The intermediate and high-pressure cylinders are single-acting, [illegible] plungers (instead of pistons); [illegible], but the heads are [illegible] to render packing [illegible]. The intermediate cylinder has poppet valves, located at one side. The high-pressure cylinder has special poppet [illegible] and [illegible] valve seats of heat-treated nickel-steel. Each valve [illegible] in a [illegible] ground to fit a tapered opening at the rear end of the cylinder. The springs are within the plugs.

The air from the low-pressure cylinder passes to an intercooler of the ordinary type, with copper tubes, while the air from the intermediate cylinder passes to an intercooler consisting of a coil of seamless copper pipe placed in the bedplate. From the high-pressure cylinder the air passes to an aftercooler consisting of a coil of heavy seamless copper pipe placed in a steel tank at the side of the bedplate. This is to provide against drop in pressure in the storage reservoir due to a fall in temperature.

Salt water is to be used for cooling, and all the iron and steel parts of cylinder jackets, intercoolers and aftercooler with which this water will come in contact have been galvanized. To avoid galvanizing the base, however, the second intercooler is placed in a galvanized tank in the base. All pipes and connections are of brass, and the drain cocks are of bronze.

Six of these compressors have been built, for six navy yards. Three of these have alternating-current motors of slip-ring type wound for 220-volt three-phase 60-cycle current, and running at 855 r.p.m. The others have 220-volt compound-wound direct-current motors with commutating poles, and running at 900 r.p.m. The compressor has a combined flywheel and gear wheel, having



THREE-STAGE AIR COMPRESSOR SUPPLYING AIR AT 2500-LB. PRESSURE FOR TESTING TORPEDOES, U. S. NAVY

(Sullivan Machinery Co., Chicago, Builders)

an internal gear bolted inside the rim. This engages with a cloth pinion on the motor shaft.

The compressors were built by the Sullivan Machinery Co., of Chicago. They were subjected to an eight-hour official test under pressures as high as 3000 lb., with satisfactory results.

San Francisco's New Municipal Street Railways

By A. J. Cleary*

SYNOPSIS—San Francisco officially declared itself in favor of municipal ownership in 1900, when the electorate adopted a new City Charter. The first proposed bond issue of $2,000,000 for a municipal railroad was defeated by a narrow margin at an election held in June, 1909; at a second election in December of the same year, the municipal-railway bond issue was carried by a three-to-one majority. This provided $1,900,000 to build an electric line on Geary St. from Market

*Assistant City Engineer, San Francisco.

to the ocean; the second applied $120,000 to the construction of a line down Market St. from Geary to the ferries.

Construction of the Geary St. railway started in the summer of 1911 and was completed in June, 1913. The cost was $103,564 per mile, and the financial returns on the money expended have been very satisfactory. Thus encouraged and realizing that the success of the Panama-Pacific Exposition depends largely on the adequacy of street-railway facilities, in August, 1913, the citizens approved a second bond issue of $3,500,000 for new lines. The entire municipal system is shown in Fig. 1. Excellent progress has been made in construction and it is expected that all of the lines will be in operation before the end of 1914.

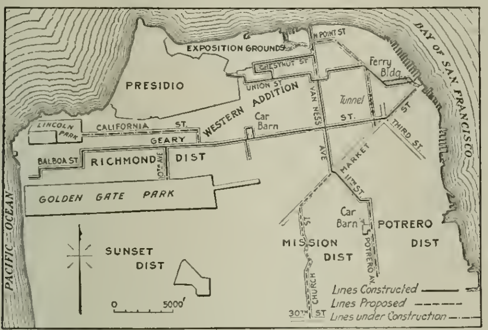


Fig. 1. Map of San Francisco Municipal Railways

Track Construction—The standard track construction consisted of 9-in., 106-lb. girder rails in 60- and 62-ft. lengths, laid on tie-plates over 6x8-in. by 8-ft. redwood cross-ties, at 2-ft. centers, with ⅞-in. round tie-rods spaced 10 ft. in straight track and 5 ft. in curves. Rails in curves are supported by braced tie-plates. Joints have 36-in., 12-bolt plates of standard section. There is 8 in. of broken-rock ballast under the ties in standard track and 15 in. for special work. Copper bonds (900,000 circ. mil) are brazed directly to the rails.

The curves have been designed to give passing cars a clearance of not less than 12 in. All track special work is of solid manganese steel and consists, so far as possible, of interchangeable switches, mates, frogs and cross-pieces, which, in various combinations, will compose any layout of branch-offs, cross-overs and right-angle crossings or combinations thereof, in standard 9-in. track. In the design of these standard pieces, an endeavor was made to reduce the number to a minimum, as their interchangeability will facilitate maintenance. The total number of pieces of different design is 35. The section of all joints in track special work is such as to permit the use of the standard joint plates without modification.

Construction Work—In order to hasten construction, several labor-saving devices were introduced. A 3-in. sharpened circular steel flange attached to the wheel of a steam roller, was used in cutting the asphalt surface of the street pavement. The top and the concrete base beneath were then broken by a 2-ton drop-hammer pile-driver, mounted on skids to permit swinging from side to side of the trench and moving forward as the pavement was broken up. The broken concrete base was next removed from the trench and fed to a movable crusher, which reduced it to ballast size. The roadbed was then excavated to subgrade, by means of a half-yard steam shovel, and 6 in. of crushed concrete was spread and flushed with sand. After this the surface was compacted with a 10-ton steam roller.

Ties were laid, rails were placed on tie-plates, joints were bolted temporarily and the rails spiked to gage. The maximum permissible variation of gage from standard (4 ft. 8½ in.) is $\frac{1}{16}$ in. All rail bending to horizontal and vertical curves was done by the contractor—part in the field by a hydraulic bender operated by a hand pump, and part by power machines at the rolling mills or railroad shops. Such drilling and reaming as was necessary was done with a portable electric track drill. After spiking, the lining and surfacing gang adjusted the track to perfect line, gage and grade. Finally the spaces between ties were filled with ballast, the concrete base for header blocks and pavement was poured and the pavement replaced.

Cars—For the Municipal lines, 125 new cars have been purchased. They are of the "California semi-steel" type, 47 ft. 1 in. long over bumpers, 9 ft. 2½ in. wide and 11 ft. 8 in. high from the top of the rail to the top of the trolley board. All structural parts, up to window sills, are of steel and so formed as to give extreme rigidity with minimum weight. The construction above the window-sill line is of the finest grades of California wood. For instance, the roof has no inner lining as the roof boards were of white cedar, which was purchased in San Francisco by the car builders and shipped east to the factory. This wood was selected for grain and color and has been varnished, presenting a very pleasing appearance and reducing the weight of roof structure without sacrificing strength.

Each car has four 60-hp., 600-volt interpole motors with multiple-unit switch control. The cars can be rapidly accelerated to full speed and can surmount heavy grades at normal speed. Special additional features in air-brake equipment have been provided as emergency devices. A valve under the body will set the brakes if air-brake pipes or appurtenances are disabled; at each end of the car, within reach of the conductor, is an additional emergency valve.

Fig. 2. Special Trackwork of San Francisco Municipal Railways, at Van Ness Ave. and Geary St.

Construction of the Municipal Railroads and their equipment is under the direction of M. M. O'Shaughnessy.

City Engineer. T. W. Ransom is Consulting Engineer, L. E. Hunt is Chief Assistant Engineer and N. A. Eckart, Engineer in Charge of Construction. P. J. Ost & Ebersold, Engineers.

A Large Coaling Station at Toledo; L. S. & M. S. Ry.

A large coaling station for locomotives forms a part of the shop and terminal improvements recently completed by the Lake Shore & Michigan Southern Ry. at Air Line Junction, about four miles west of Toledo, Ohio. It is of the bridge type, spanning seven tracks, and has an overhead storage bunker of 1000 tons capacity, with a weighing hopper over each track. Provision is made also for delivering sand to the engines. Water cranes are located along the engine tracks which pass under the coaling station. About 80 locomotives take coal daily at this point, with an average supply of 8 tons per engine.

FIG. 1. A LARGE COALING STATION ON THE LAKE SHORE & MICHIGAN SOUTHERN RY. AT AIR LINE JUNCTION, OHIO

([illegible])

The construction is shown in Fig. 2, and Fig. 1 is a view of the completed coaling station. The steel bunker structure is about 150 ft. long, supported on four rows of columns 37 ft. 6 in. c. to c. [illegible]. At one end is the tower of the elevating conveyor, carrying the coal from track hoppers at the base, and this end is fitted with diagonal bracing to resist any tendency to longitudinal movement. At the further end the structure extends as a cantilever about 18 ft. beyond the columns, so as to serve the [illegible] track. The side sheathing and the roofing are of corrugated sheet iron. The erection was done with a stiff-leg derrick, having a 115-ft. boom, the derrick occupying one position during the entire work.

At the elevator end, there are two coaling tracks, each with two track hoppers of reinforced-concrete construction to receive the coal from dump cars. Beneath each pair of hoppers is a cracker for breaking large lumps and sizing the coal. A feeder of the reciprocating plate type carries the coal from the discharge opening of the hopper to the cracker. If the sizing is not necessary, the coal can be delivered directly to either of the two elevating conveyors, being fed to the buckets by a revolving loader having four buckets and driven from the conveyor chain.

The two conveyors have chains of steel-bar links $17\frac{1}{2}$ in. long with 6-in. rollers riding on a channel track. The buckets are 30 in. wide, spaced 35 in. apart, and each holds about 250 lb. of coal. The conveyor runs vertically in the inclosed end tower and then extends horizontally over the storage bunker, the buckets being dumped by means of tilting devices, which can be set at any desired point in the horizontal line of travel. These dumpers have cams which engage with cams on the buckets. The driving mechanism is mounted above the bins, and each conveyor is driven at a speed of about 10 ft. per min. by a 25-hp. motor.

Over the track and beneath the discharge gate of the bunker hopper, is a weighing hopper of 20 tons capacity. This is filled with coal and the total weight taken. When an engine is spotted under the weighing hopper, the spout is lowered, the rocking gate opened and the coal dumped on the tender until the enginemen signals that enough coal has been delivered. The gates are then closed, the spout raised and the operator weighs the remaining coal. The difference between these two weights is the amount of coal which has been received by the engine. The tickets upon which this information is printed are sent daily to the accountants, who then issue a coal report at the end of the month.

Each weighing hopper is supported on a 30-ton scale, with type-registering beams placed in the weighing house. The poise on the scale beam has a slot into which a card is inserted, and as a lever on the poise is pressed down, the weight is recorded on the card. The scale man in this cabin has control of the weighing apparatus, the levers operating the gates of the storage bunker and weighing hoppers, and the levers operating the coal chutes to the tenders. From his cabin he has a clear view of the tracks.

There are three sand tanks of 10 cu. yd. capacity, supplied with sand from a dryer. The delivery spout is adjustable and is protected from rain and sleet. The sand valve is [illegible] and of the undercut type, its edges overlapping the discharge openings so that it is sand-tight

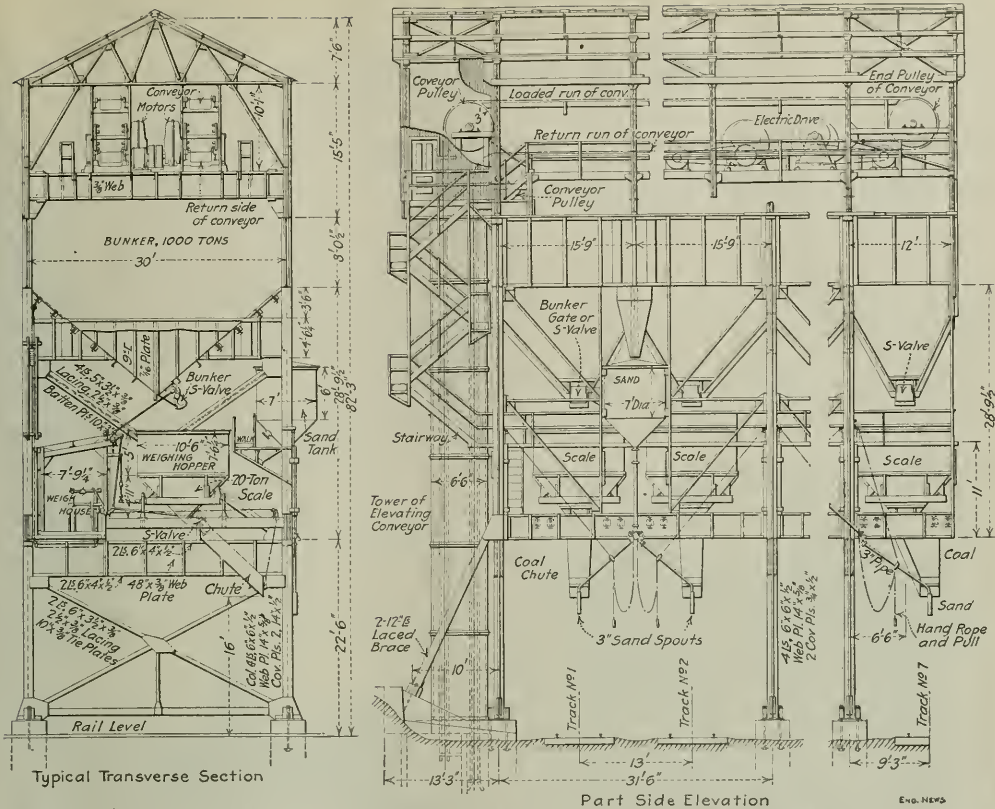

FIG. 2. COALING STATION FOR THE LAKE SHORE & MICHIGAN SOUTHERN RY. AT AIR LINE JUNCTION, OHIO

when closed. The valve and spout are controlled by the fireman on the engine.

This coaling station was designed and built by Phillips, Lang & Co., of Chicago, and its machinery equipment was furnished by the C. W. Hunt Co., of New York. The work was under the general direction of G. C. Cleveland, Chief Engineer of the Lake Shore & Michigan Southern Ry.

Methods of Taking Records of Street Traffic

The following suggestions for a traffic count are abstracted from the report of the Committee on Way, presented at the recent annual meeting of the American Electric Railway Association:

The period to be covered should be 14 consecutive hours, from 5 a.m. to 7 p.m., and during six consecutive or different week days. However, if average weather and traffic conditions are known and selected, the record may cover only three consecutive week days. No traffic should be counted in abnormal weather, such as seasons of snow and ice, nor during continuous rainy, very hot, or excessively cold days, and holidays. The location of the count should be at or near the center of a block and not at any street intersections and traffic both ways must be counted. The observer may be stationed upon the walk, but an elevated position is better and a room facing the street is best.

The general classification of vehicles for practical results is as follows: (1) Horse vehicles; subdivided into one-horse, two-horse, three or more horses; (2) motor vehicles.

The horses as well as the vehicles must be considered in computing weights of traffic from the quantities counted and recorded, because the horse, as well as the vehicle, helps wear the pavement and occupies space. Experience in such counts shows that for general record purposes the average weight of all one-horse vehicles (empty and loaded) can be taken as one ton (2000 lb.); two-horse vehicles as two tons; three or more horse at four tons. Similarly the average of all motor vehicles (empty and loaded) for transportation of persons and goods may be taken at 1¾ tons. Exclude all bicycles, motorcycles and ridden horses.

The record is made on a set of four cardboard slips of different colors, each about 2x9 in., and fastened together by a clip near one end; 14 sets are needed per day, one for each hour. If traffic is extra heavy, more than one set can be used for each hour. Each set is marked for location where count is taken, name of observer, date, hour covered by the set, and the number of standing vehicles. Two observers are required, to relieve one another at the end of each hour, because one recorder cannot work accurately for a longer period.

An ordinary conductor's punch is used and a hole is punched in the proper slip for each vehicle passing in either direction in front of the recorder. One-horse vehicles are punched in the white slip; two-horse in the blue; three- or more horse in the red, and motor vehicles in the yellow slip. Each slip bears a heavy ruled line in the center, lengthwise, and vehicles which are outside of the car tracks are punched above this line and those inside of tracks are punched below the line. A vehicle is to be considered as being in the tracks if the two wheels farthest away from the recorder are on the tracks inside the gage line of the rail nearest the observer.

The number of vehicles standing at curbs is taken generally every two hours, by the relief observer, just prior to the hour, and is recorded on the slips. The number of holes in each slip are not counted until a recorder has stopped observing traffic, either after relief or at the close of the work. The number of holes counted should be written on each slip.

Field and Office

Floating Lock-Gate Lifter for Trent Canal, Canada

The two accompanying views show the new lock-gate lifter which has recently been built for the Department of Railways and Canals of Canada for service on the Trent Canal in Ontario. Its capacity of 50 tons and a clearance above the deck of 27 ft. will enable it to step any of the mitre gates on the canal. The machine consists of a structural-steel collapsible derrick mounted on a steel pontoon, with separate steam engines for operating the derrick, lifting the gates and controlling the balancing weights.

The pontoon supporting the derrick is made of steel plating with extra-strong steel framework, there being two longitudinal and three transverse trusses. Its length is [illegible] ft., beam 27½ ft., and depth 9 ft.

The derrick is hinged at mid-height so that the upper part can be lowered to clear the bridges over the canal.

Fig. 1. In Working Position

Fig. 2. Lowered to Clear Bridge

Floating Lock-Gate Lifter for Trent Canal

Its working position is shown in Fig. 1. In transporting the lifter from one lock to another the upper part is lowered as shown in Fig. 2. The operation of raising and lowering the derrick is controlled by a [illegible] cylinder engine mounted on one of the back legs [illegible]. The gates are lifted through the medium of two [illegible] which are suspended by [illegible] steel cables from the [illegible] of the front legs of the derrick. This lifting is controlled by a [illegible] engine. The operating levers of all engines are brought to one position for the convenience of the engineer.

The pontoon is kept on an even keel during the lifting process by two movable ballast cars under the deck. Each car is moved by a screw operated by an independent engine, which is controlled by pendulum governors automatically moving the ballast to the proper position to put the pontoon on an even keel. In addition to the automatic control the ballast-car engine can be operated from the engine room above deck. Dial indicators are provided there to show the position of the ballast cars at all times.

The device has been used in stepping the gates on the locks of the Ontario-Rice Lake division of the canal and has met all expectations. The total time for stepping each leaf is 20 min. (upper leaf) to 40 min. (lower leaf).

The machine was built by M. Beatty & Sons, Ltd., of Welland, Ont.

Sediment Test for Water and Other Fluids

By Robert Spurr Weston*

For some time a simple device has been used successfully for determining the amount of visible sediment in milk. It was suggested by Prof. George C. Whipple, of Harvard University, that this test be applied to waters, especially those containing suspended algae or other organisms, suspended iron, silt, etc.

The method was illustrated by Professor Whipple in connection with a committee report at the annual meeting of the New England Water Works Association, Sept. 9, 1914, and again at the meeting of the American Society of Municipal Improvements on Oct. 6, 1914.

Briefly it consists in straining a measured volume of water (1 pint) through a disk of cotton felt 25 mm. in diameter and 1 mm. thick. The operation requires but [illegible] of filtration and the result is a visible record of the suspended matter, which record is far more intelligible to the average man than any numerical expression—for example, of "suspended solids," "albuminoid ammonia" or "microorganisms."

*Consulting sanitary engineer, 14 Beacon St., Boston, Mass.

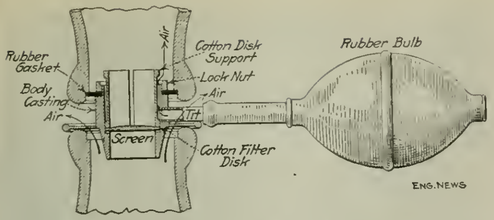

Fig. 1. Sediment Tester in Position for Use

The tester (Fig. 1) consists of a device for holding the cotton disk. The holder has a rubber gasket so that it may be slipped into the cap seat of an ordinary milk bottle. There is a woven-wire screen for supporting the disk in the holder and a rubber bulb for forcing the air into the bottle. After the disk is placed in the holder, it is slipped into the neck of a milk bottle full of water, the bottle is turned upside down and air pumped in to displace the water and force it through the disk.

The disks, after the water has been passed through them, are dried and mounted on sheets of paper.

By determining the sediment in the water at stated intervals, it is possible for any water-works manager to obtain an excellent record of the visible appearance of a water-supply from time to time. It is also very useful in determining the degree of growth of microscopic organisms in various ponds forming the sources of one

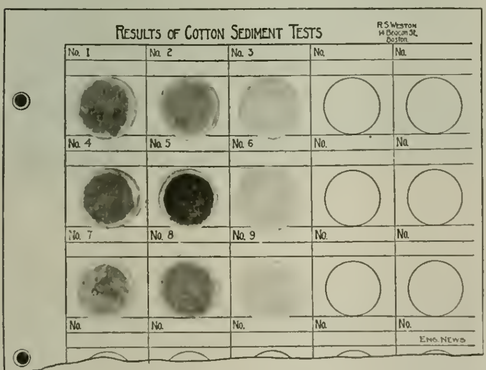

Fig. 2. Cotton Disks After Use for Testing Water for Sediment

(In the practice of the author, these disks are mounted on blank forms, made up as 8x11-in. loose-leaf sheets. Half of one of these sheets is here reproduced.
The samples were taken from the following sources:
1. Charles River at Cow Bay.
2. Wells, Brookline Water-Works.
3. Experimental filter effluent, Brookline Water-Works.
4. Reservoir, Belfast, Me.
5. Coagulating-basin effluent, Belfast, Me.
6. Filter effluent, Belfast, Me.
7. Reservoir, Exeter, N. H.
8. Coagulating-basin effluent, Exeter, N. H.
9. Filter effluent, Exeter, N. H.
Obviously, the colors of the original are lost in the reproduction. To some extent, the relative shades of the originals have also been lost.)

supply; also in determining the relative clearness in different parts of a distribution system, of a water which contains suspended iron rust or silt.

Before the method was published, Professor Whipple suggested its use to the writer, who has made use of it during the past summer with a great deal of satisfaction. Fig. 2 illustrates the results of nine of these tests.

The testing device here described is known as the Wizard Sediment Tester and is made by the Creamery Package Manufacturing Co., of Albany, N. Y. The company also supplies cotton disks for use with the tester.

An Instrument for Recording Roughness of Pavement Surfaces

For the graphic measurement of inequalities in street surfaces, an instrument called the "trafilog," operating on the inertia principle, has been used in Cleveland, Ohio, by a subcommittee of the general good-roads committee called together a few months ago by the Cleveland Chamber of Industry. By attaching this instrument to the floor of a vehicle, charts are obtained containing records of the riding qualities of the streets traversed.

The "Trafilog," an Instrument for Recording the Roughness of Pavement Surfaces

To explain the accompanying illustration, the button *A* on the right is for starting and stopping the rotation of the chart. The chart is mounted on a disk and driven by a clock train. The lower horizontal arm is one of a pair of parallel links which support the clock movement. The movement is counterbalanced by a flat-leaf spring, *B*, a curved part of which is seen on the right. On the left is an oil dashpot *C* for damping the oscillation. The marker *D* has a jewel stylus which scratches the surface of the chart. The chart is a specially prepared paper with a white coating over a dark base.

The pen of the instrument is geared so that a horizontal line is drawn on the face of the chart by the clock movement; a vertical line is made when a wheel of the vehicle drops into a rut. When it comes out of the rut or strikes a bump the direction of the line is reversed. The length of the mark is proportional to the depth of the rut, and the steepness of the lines indicates the nature of the edges. There is no provision to take care of vibrations or usual lateral swings of the vehicle.

The instrument is set on the floor of the vehicle and held down by the observer's feet resting on the base plate, although for continuous or extended runs the instrument is mounted on a bracket in front of the observer. The instrument was devised by W. H. Brown, and is made by the Brown Traffic Co., Rose Bldg., Cleveland, Ohio.

Removing Subway Excavation Spoil with Portable Bucket Elevators

Portable bucket elevators are being used on Section 3, Division 1, of the new 7th Ave. subway on Greenwich St., near Reade St., New York City, to lift excavated dirt to the street. With this type of machine, large street openings are unnecessary, as the standard 24-in. manhole is utilized by extending the bucket chain by means of an idler shown in Fig. 1.

The elevator, illustrated in Fig. 1, is self-contained and consists of a timber frame, chain and buckets, motor and driving mechanism, and feet. The buckets are 8x5 in. and spaced 18 in. on the chain. The outfits can handle 15 to 20 tons of dirt per hour each and are kept fairly busy on this job.

Fig. 1. A Portable Bucket Elevator on Subway Excavation in New York

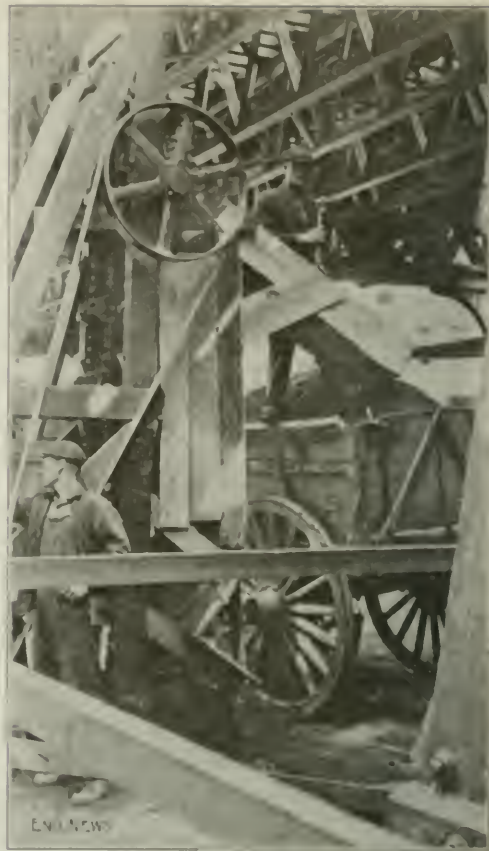

Fig. 2. Cart Being Loaded from Chute Fed by Buckets

The dirt is shoveled or dumped from wheelbarrows into the boot at the foot of the elevator, lifted to the street and chuted into carts, as shown in Fig. 2. A cart is loaded in 10 to 15 min.

When the digging has progressed sufficiently to make it desirable to move the elevator to a new location, the chain (which is of the [illegible] type) is removed from the sprocket in the foot and hauled up on the framework. The whole is then moved where desired. The foot is made to pass through a manhole, so it travels along under the street surface. Manholes are located about 100 ft. apart.

The Degnon Contracting Co. has four of these bucket elevators in operation at the location named. They were furnished by the Robins Conveying Belt Co.

The Efficiency of Clamps on Tie-Rods in forms for concrete work [illegible]

Calibrating Some Venturi Meters for Air Flow

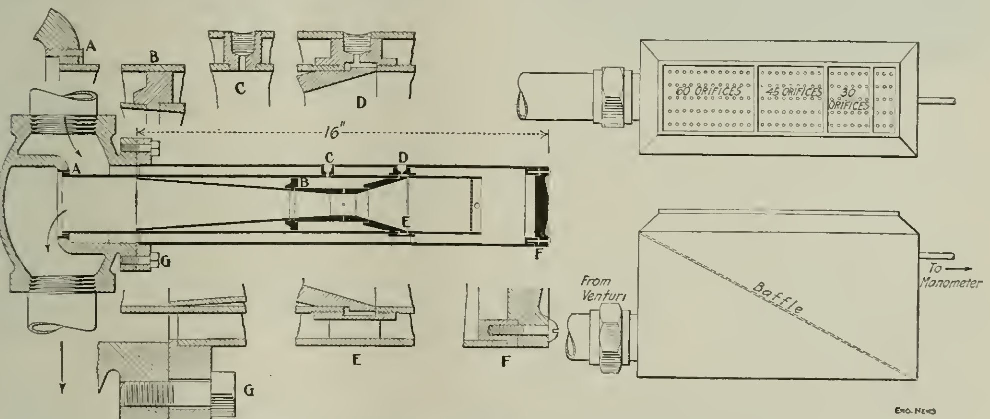
In the design of the Brooklyn Sewage Experiment Station under Geo. T. Hammond, Engineer of Sewer Design, Bureau of Sewers, Brooklyn, N. Y., one of the troublesome problems was in securing a meter for the compressed-air lines. On account of the quantity of air used and the pressure, no form of available gas meter was found to meet the requirements. Therefore, special Venturi meters were designed jointly by Mr. Hammond and Wallace & Tiernan, of New York City. Interest attaches first to the method of calibration and only somewhat less to the details of the meters.

Calibration—The calibration method is of unusual interest and wide application. On account of the quantity of air flowing, it was impractical to use a gasometer for calibrating the meter. Therefore, a special multiple-orifice box was built to receive and measure the air passing through the meter. The top of the box was a metal plate having, in all, 150 orifices of the same size (punched with the same die) equally spaced. This top plate had a cover so arranged that any number of orifices from 1 to 150 might be left open. The orifices were designed to discharge 1 cu.ft. per min., under a head of 10 in. water pressure. A perforated metal screen, placed diagonally across the box, prevented eddy currents. Preliminary readings were made with a small gasometer to determine the air flows from different orifices (for rating the calibration box) and from different groups of orifices to see if there was any variation because of location or number of those discharging. It was found that the flows agreed within ½%.

In calibrating a meter, the box was connected to the air line through the meter and a certain number of orifices were uncovered on the top of the box, a stop valve being opened until the desired head was shown on the box manometer. Knowing the discharge for this number of orifices and the corresponding pressure, it was a simple matter to mark on the Venturi-manometer scale the flow corresponding to the height of liquid. The scale was then fully graduated in cubic feet per minute after having determined several of these points.

Venturi Meters—The specifications, according to which the Venturis were made, called for three sets of meters; one reading from 20 to 150 cu.ft. per min., one from 5 to 20 cu.ft., and a third from 1 to 30—all operating under a pressure of about 40 lb. per sq.in. In order to secure the desired range with accuracy a type was designed with interchangeable throats. To secure accuracy through the range indicated, five meters would ordinarily be employed. Such multiplicity was ingeniously obviated in this case. The meters were assembled in tubes of the same size so that any one could be screwed into the body of an ordinary 3-in. check valve put in the air line. There were three barrels complete, with Venturi throats, etc., for each meter. Two of these three barrels were of small capacity and each had interchangeable throats, while the third was larger and had but one throat.

Air passes from the check valve (following the arrow in the upper left of the section of the meter shown in the accompanying drawing) along the meter barrel, through the throat and out through the air line again.



Venturi Meter for Air Flow and Multiple-Orifice Calibrating Box

To put in a larger or smaller throat giving the desired capacity, the barrel cap is removed, the approach tube screwed out of its bushing, and the throat approach and throat taken out. Without displacing further parts, the smaller or larger throat is inserted. All parts were made of brass and bronze.

The manometer intended for use with these Venturis was of special design. The cross-section of the oil reservoir was made many times greater than that of the manometer tube, so that the zero point was practically unaffected through the range of the scale. The upper end of the manometer tube, which was connected to the Venturi throat chamber, had a reservoir interposed of capacity slightly greater than that of the lower reservoir. This was done to prevent blowing any of the oil into the pipe line by sudden rushes of air.

It may be added that these meters are used to measure compressed air supplied in experiments on the aëration of sewage. The entire equipment of the Brooklyn Sewage Experiment Station was described in Engineering News, Oct. 22, 1914. The same issue contained a short article on the calibrated orifices for controlling sewage flow at the station just named.

A Contractor's Coal Scow with Portable Motor

In designing ditches and an outlet from a lake for purposes of drainage, the contractor found difficulty in getting fuel to the dredge. The shore being of very soft soil, he could not haul the coal near the work, but was compelled to unload it at a road crossing and one other point where the high land came near the ditch, and it was necessary at times to carry it in a scow for about two miles to the dredge.

A Contractor's Scow Fitted with a Portable Motor and Carrying 8 Tons of Coal to a Dredge

The machine requires 5½ tons of coal per day and has storage capacity for 30 tons. The plan is to handle one 8-ton load daily until the bunkers are full, and then wait a day, or if the weather is bad two days may be missed.

The coal scow is 12x18 ft., 28 in. deep, and carries about 8 tons. It is slow and difficult work to navigate it by hand, the ditch being 18 ft. wide on top and 11 ft. deep. The contractor therefore purchased a portable marine motor of 3½ hp., made by the Evinrude Motor Co., of Milwaukee, Wis. With this a speed of 4 m.p.h. is made, while the scow is easily handled. This loaded motor scow is shown in the accompanying cut. The motor has a frame hooked over the stern of the boat and carries a little gasoline motor at the head of a vertical shaft, geared to the short propeller shaft at its lower end. No rudder is required, the propeller being shifted to steer the boat.

The same motor is used on the scow which carries the men from the house-boat to the dredge. When the house-boat is to be moved, it is towed by the empty coal scow. The adoption of this device enables the contractor to use roughly made and cheap barges, which will stand the rough handling, and yet have the advantages of power equipment and save the expense of a gasoline launch for towing.

The work is in Emmet County, Iowa, and the contractor is D. C. Stephens. For information we are indebted to H. B. Whitney, manager for the contractor, Hippee Building, Des Moines, Iowa.

Novel Method of Trench Excavation

By J. C. Lattimer*

The accompanying views illustrate a novel method used by the Ault Construction Co. in excavating a trench for a water main installed by the city of Baltimore, near Clifton Park. The main is of reinforced-concrete pipe, with an inside diameter of 7 ft., the shell being 7 in. thick. The pipe sections are 8 ft. long and were cast in a yard near one end of the trench. The length of the trench dug by the Ault Construction Co. was about 1700 ft. The average depth was 15 ft., varying from 12 ft. at one end, to 20 ft. at the other, while the width was 13 ft.

The method used in trenching is plainly shown by the accompanying illustrations. A dragline bucket with a capacity of 22 cu.ft. was pulled up an incline by an

*Baltimore, Md.

Fig. 1. Incline and Dumping Tower for Dragline Excavator

Fig. 2. Dragline Excavator for Sewer Trenching

ordinary contractor's engine and dumped into a hopper which delivered the earth to carts or wagons.

The total amount of earth removed by this method was approximately 13,000 cu.yd., one-quarter of which was hauled away to allow for the space occupied by the pipe. The balance was piled up at one side of the trench to form an embankment, upon which was placed track for a locomotive and locomotive crane to handle the concrete pipe sections.

The essential reason for adopting this scheme of excavation instead of a steam shovel was that, owing to the character of the material, the banks would not stand without supports. It was found necessary to carry down 2-in. sheeting as the excavation proceeded. Waling strips 6x8 in., about 16 ft. long, were held in place by vertical 6x8-in. timbers, which were cross-braced at the top and intermediate points by other 6x8-in. timbers. At the bottom of the trench 6x8-in. timbers were placed at intervals, so spaced that they would come directly under the joints of the concrete pipe. Concrete was placed under the pipe and between the timbers to prevent settlement.

The sheeting was driven by two small steam hammers, which were carried by block and falls hung from steel cables directly over each line of sheeting. Steam for these hammers was taken from the boiler which supplied the hoisting engine. The capacity of this boiler being insufficient, its output was supplemented by that from a traction engine.

This work proceeded rapidly, as high as 250 scoopfuls being removed in one working day, which means an average of a round trip in two minutes. The sheeting and bracing were carried along simultaneously.

The Ault Construction Co. has another contract for a similar trench in which the material is all solid rock which has to be blasted. They are using a similar device for removing this material.

WHAT IS GRAVEL?

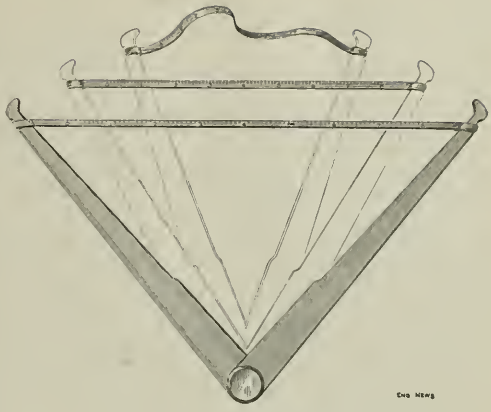
A concise and clear definition of gravel is desired by manufacturers of machinery for excavating and handling this material. What maximum size, proportion and character of stones mark the line between gravel and boulders, when (for instance) a machine is guaranteed for handling "gravel." The dictionary definitions are not sufficiently clear and explicit to meet the requirements of the case. Probably many of our readers have encountered this problem in different ways, as in the classification of material for excavation, and we shall be glad to have their views in the matter.

NOTES

An Ingenious Proportional Scale—Something new in the way of proportional scales for measuring or transferring dimensions has been worked out by F. J. Winters, draftsman, New York City, for use in his own work. The device is sketched herewith. A piece of narrow elastic webbing is stretched between the points of a pair of firm-joint straight-leg calipers. A scale is inked on this webbing, and by changing the spread of the calipers this scale is stretched or shortened to suit the needs of the case.

Whoever has experienced the bother of trying to read dimensions from a drawing which contains possibly half a dozen different-scale sketches will appreciate this device. The device proves especially useful when the scale of a drawing is not given, but a particular dimension is shown, as, say, 7 ft. 10¼ in., in which case there is some difficulty in finding the scale of the drawing in the ordinary way, while with this proportional device the proper setting is made instantly.

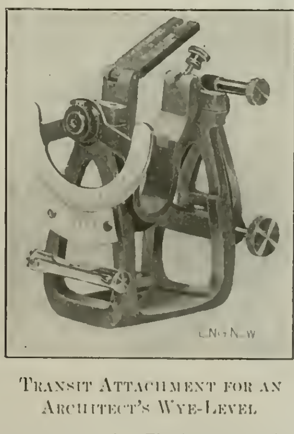
In inking the scale on the elastic band—which is simply



An Ingenious Proportional Scale

narrow elastic hat tape of best quality about $\frac{3}{16}$ in. wide—the markings are made when the band is stretched out. They must be made with a fine-pointed brush dipped in India ink, as a pen will pull the tape out of line and falsify the dimensions or markings. When the band is let go, the marks become fine and sharp. The chief difficulty with this device is that the tape does not retain its proportionality of stretch in the different parts of its length more than three or four months, when a new band must be put on. For those who have much proportional measuring to do, it is of such value that even the frequent replacement of the measuring band is no great objection.

A Wye-Level with Transit Attachment—A new type of surveying instrument has recently been put on the market which combines a 12-in. architect's wye-level with a transit attachment. Obviously the transit is not intended for accurate survey work, for the horizontal and vertical circles read only to 5′. It does answer, however, for laying out buildings and similar work, while used as a wye-level it has much greater accuracy than a cheap transit; and accuracy in leveling is an important factor in the work for which the instrument is designed. The instrument is built like an ordinary wye-level except that it has a horizontal circle below the level bar. In the center of the level bar is a threaded hole into which fits a thumbscrew for fastening on a transit attachment (shown in accompanying illustration) consisting of telescope standards, a 50° vertical arc, reading to 5′, and a level vial. The level telescope is mounted in these standards and the instrument is ready for use as a transit. The instrument is made by Geier & Bluhm, Troy, N. Y., and is listed, complete with tripod and accessories, at \$60. The transit attachment alone is listed at \$10, and can be made to fit any architect's level.



Transit Attachment for an Architect's Wye-Level

A Method of Interpolating Slope-Stakes on Uneven Ground—I had occasion recently to run a survey line crossing a number of small drains, diagonally. The ridges between were not high, approximately 15 ft., and the distance from ridge to ridge varied from 100 to 250 ft. The profile of the line was to be a balanced one, and the side slopes were to be carefully done to give a good appearance, and were to be sodded. To secure nice, even slopes, I realized at once that

The Mechanical Engineer in Municipal Engineering

A notable and unprecedented feature of the coming annual meeting of the American Society of Mechanical Engineers, to be held in New York City during the first week in December, is the devoting of one entire day to papers and discussions on the general subject of municipal engineering. It has hitherto been generally accepted that city engineering work was matter with which the civil engineers had solely to do. Such work as city surveying, paving and sewerage are well recognized as belonging to the civil engineer, primarily. On the other hand, other functions which are becoming more and more prominent in the administration of cities at the present day, such as electric lighting, street railways, treatment of garbage and refuse, necessarily bring in the mechanical engineer to a large extent.

The mechanical engineer, moreover, is laying claim to be considered as an administrator as well as a technical employee. In the broad field of administrative work, the engineer needs, of course, a general grasp of professional knowledge rather than special details. The engineer appointed as a city's general manager, for example, must, through his subordinates, deal with every aspect of municipal work, from the laying out of street grades to the purification of the boiler water-supply in a power station. There need be no jealousy or rivalry, therefore, between the civil and mechanical branches of the profession in municipal engineering work, and in fact a number of those who are on the program for papers at the Mechanical Engineers' Convention on Municipal Day are prominent civil engineers. What is the most important consideration of all is that such an emphasis by a public meeting of the engineer's part in carrying on city administration cannot but have a useful effect in the formation of public opinion as to the value of the engineer's service in the municipal field.

Continuing Activity in the Building Industry

The returns made to Engineering News by the building departments of 17 Eastern cities of the building permits issued for the month of October show a falling off of only 8% in the total value of buildings for which plans were filed during that month as compared with October of 1913. In 20 cities of the Middle West there is a considerably larger falling off, but it is not uniform, and some cities, such as Cleveland, Columbus, Des Moines, Duluth and St. Louis, report more building plans filed last month than in October, 1913.

This is the most notable evidence of returning business confidence and the revival of prosperity that has anywhere appeared. It is a far better index of what may be expected in the near future than any record of current business transactions in the iron and steel market or the clearing-house exchanges. It shows that a large proportion of real-estate owners have confidence enough in the future to carry on work previously planned to the stage of actual construction. It may be assumed where plans are filed for a building that arrangements have been completed for financing its construction. It means, furthermore, that the people who are putting up these buildings believe that the times will be prosperous enough when these buildings are completed, six months to a year hence, so that tenants will be then found for the dwellings and apartments and stores. Moreover, the lists of new buildings include some factories. Certain lines of manufacturing, the woolen industry for example, have been so active during the last few months that they are forced to enlarge their facilities for production. This is most cheerful news to come at a time when even the professional optimist has a hard struggle to maintain his reputation.

Handling Materials on Highway Construction

The fact that road building has been the most active branch of construction work carried on extensively during the past year or two, probably explains why many construction firms whose previous experience has been in railway construction have turned to highway contracting. With them into this work the railway builders have brought methods and equipment, which have gone far to raise the status of the highway contractor. For, while a few years ago the average road contractor was an enterprising farmer or labor foreman, using teams hired by the day from the neighboring farmers, the present-day ex-railway contractor uses an industrial railway, or tractors and dump wagons, or motor trucks, for hauling his materials.

Which of these three new methods to use is always a problem to be solved by many considerations, based on topography, railway service, character of the highways, and many more elements which must be known and studied in advance if the most economical solution is to be made. Perhaps, however, the most interesting development in the solution of this many-sided problem is the apparent increase in popularity of the industrial railway. These are being used successfully on roads having grades as high as 7 or 8%, with the help of pusher engines.

Motor trucks and tractors generally have to navigate some pretty rough going, which is always the case when the new road, torn up in advance of pavement laying, is the only access to the work, for if the hauling is done from the other end, the traffic of the tractors and trucks is not good for the newly made pavement.

On the other hand, the narrow-gage railway laid on one side of the roadway may be so placed as to be seldom or never disturbed, and furnishes ready access to all parts of the work, before, during and after construction. Moreover, small cars on rails are generally easier to handle than heavy dump wagons and traction engines, while

motor trucks have the disadvantage of wasting considerable time and capital while being held at the terminal point for loading.

Like all construction problems, this is one that cannot be decided offhand in the office; but the possibilities of the [illegible] railway for construction work of all kinds is often not appreciated by contractors who have never had experience in railway building.

Where the highway right-of-way is wide enough and has fairly level grades, a contractor might go even a step farther and extend standard-gage tracks to the work, thus avoiding any rehandling of the materials whatsoever. Another possibility is the use of trolley tracks or temporary extensions of trolley tracks.

The Panama Canal and the Transcontinental Railways

During the quarter century since the construction of a transoceanic canal across the Central American Isthmus became a live issue, a vast deal has been printed regarding the effect of such a canal upon the transcontinental railways. It has been very generally assumed that the canal would be a serious detriment to these railways on the one hand, and on the other that its construction would be particularly advantageous to the states on the Pacific coast to relieve them from the alleged exorbitant freight charges of the railways from the East. In recent years, however, a saner view has gradually gained ground, and it has come to be realized by those closest to the problem that the amount of railway traffic which the canal will affect and which will be diverted to the canal will be, after all, comparatively small. Further, it is seen that the stimulating effect upon certain lines of trade and business resulting from the canal will have in all probability some compensating benefits for the railways.

Some attention is given to this matter in the annual report of the Northern Pacific Railroad Co., just issued. The report says:

> The [illegible] of the [illegible] [illegible] out of the ports on [illegible] [illegible] [illegible] for the [illegible] [illegible]. The [illegible] of the Northern Pacific at the head of Lake Superior [illegible] are more than [illegible] miles [illegible] the average haul of a ton of freight on the [illegible] [illegible] last year was only [illegible] miles.

These figures indicate how comparatively small is the percentage of the freight traffic which moves from coast to coast. A considerable part of this traffic also will be carried by the railways notwithstanding the [illegible] of the canal route. For certain high-class merchandise it will be cheaper to pay a somewhat higher freight rate and have the shipment go through by rail in a week or less rather than incur the delay of nearly a month required for the voyage from a north Pacific port to a north Atlantic port through the Panama Canal.

An Explanation of the Autoclave Test for Cement

When the [illegible], some two years ago, of the [illegible] pressure accelerated test of the soundness of cement, [illegible] the "autoclave test," engineers were [illegible] to [illegible] for any good explanation of why a cement which passed quite sound under the ordinary boiling test would show decided unsoundness under the high pressure and temperature of the autoclave. The failure of the opponents of the test to furnish any adequate explanation of this phenomenon was undoubtedly the main reason why many were ready to accept the claims of the autoclave adherents, although these claims were often injudiciously advanced and pressed.

In the U. S. Bureau of Standards "Notes" in the *Journal* of the Franklin Institute, November, 1914, Messrs. A. A. Klein and A. J. Phillips present an abstract of a study on the hydration of portland cement, in which are included three paragraphs which, if not an explanation, are at least an interpretation of the frequently observed behavior of cement in the autoclave. The paragraphs follow:

> On the hydration of cement the first constituent to react is the aluminate with the formation of amorphous hydrated tricalcium aluminate, with or without amorphous hydrated alumina. The sulpho-aluminate crystals are also formed, and the low-burned or finely ground lime hydrates. This occurs within a few hours after the cement is gaged. The next compound to hydrate is the tricalcium silicate. This commences within 24 hr. and is generally completely hydrated within 7 days. Between 7 and 28 days the amorphous aluminate commences to crystallize and the beta-ortho-silicate, the least reactive compound, begins to hydrate. The 24-hr. strengths are due mainly to the hydration of the aluminates and of any fine-grained, low-burned lime present. The large increase in strength between 24 hr. and 7 days is due mainly to the tricalcium silicate hydration. The increase between 7 and 28 days is due to the hydration of the beta-ortho-silicate. Where there is a decrease in strength during this period it is due to the hydration of very high-burned free lime, as in very high-burned, high-limed cements, or to the crystallization of the aluminates, as in high-alumina cements.
>
> Failure of cement in accelerated tests is due to the growth of large lime hydrate crystals. The disrupting action results from the pressure caused by growing crystals. Cement will fail in the boiling test which contains lime sufficiently fine and high burned, so that during boiling it hydrates and crystallizes. The growth of crystals is sufficient to cause disintegration. When a cement passes the boiling test but not the autoclave test, it contains lime so coarse or high burned as not to hydrate in the boiling test, but only in the autoclave, due to the high temperature and pressure employed. Some cements will pass either test only after aging. In this case aeration with insufficient water to allow solution and crystallization [illegible] the lime to hydrate as amorphous hydrate, and in the accelerated tests there is no crystallization and no disintegration.
>
> The reactions when cement is subjected to the autoclave test are not abnormal. The disintegrating action attributed to the crystallization of the sulpho-aluminate has been greatly exaggerated.

It remains now for someone to show just how the "coarse or high burned" lime is sufficiently active under normal conditions to be a menace to concrete in structures.

Accurate Marksmanship in Naval Warfare

Everyone who has had occasion to become familiar with naval matters are aware of the wonderful precision in marksmanship that has been attained during the past [illegible] years in the leading navies of the world. It has been [illegible], however, that the high perfection of marksmanship attained in target practice in time of peace could not possibly be approached under the excitement of a battle. The recent naval engagement off the coast of Chile, however, appears to be a [illegible] illustration of what can be actually accomplished by a fighting ship at long range. According to the newspaper reports of the combat, the German cruisers began firing at their English antagonists at a distance of six miles, and had inflicted serious injuries upon them by the time this distance was reduced to four miles.

In a circle of six miles radius, the length of one minute of arc is approximately 9 ft. A gun trained on the center of a vessel 400 ft. long at a distance of 6 miles, therefore, if rotated only 22 minutes in the horizontal plane, would miss the vessel entirely, and a much shorter distance of rotation would cause it to miss the vital portions of the vessel. If, however, the vessel were approaching, bows on, or fleeing, with her stern toward the adversary, a cruiser of 60-ft. beam would cover less than 7 minutes of arc on the circle, so that a horizontal rotation of the gun of only three minutes from the center of the target would cause it to miss.

Of course, this takes into consideration only the mathematics of the problem. Other factors which may disturb the true flight of the projectile, such as inaccuracies in the gun, or in the projectile itself, influences of the wind, etc., and inaccuracies in the telescopic sighting instruments, have to be taken into account. Incredible though this astonishing accuracy in directing an enormous cannon, weighing many tons, may appear to the layman, it seems insignificant when compared with the difficulties of training the gun in elevation. The same figures, of course, hold good for the same range. That is, an elevation or depression of one minute of the gun about its horizontal axis will make a difference of 9 ft. in the point struck by the projectile six miles away. War vessels have usually a comparatively low freeboard, so that an error in the elevation of the gun of 1½ to 2 minutes may be sufficient to cause the shot to miss its mark. The accurate pointing of the gun, moreover, must be done not from a stationary platform but on board a ship which may be pitching and rolling. All reports agree that the recent battle off the coast of Chile took place in a severe storm, approaching a hurricane in violence.

The latest reports, in fact, claim that the largest English vessel engaged was unable to use a large part of her battery on account of her heavy roll before she had received severe injuries from her adversaries.

The engineer takes off his hat, metaphorically speaking, to "the man behind the gun," whose wonderful skill and careful use of his instruments achieve such results. But these results are also a testimonial to the marvelous accuracy of modern methods of manufacture, which can produce a gun capable of such close shooting. The modern high-power rifle may almost be compared to an astronomical instrument in the accuracy of its workmanship; but while the astronomical instrument is carefully protected against stresses which might interfere with its accurate work, the gun and its mounting are subjected to enormous stresses and shocks, notwithstanding which it must maintain its accuracy unimpaired.

Letters to the Editor

On the Thickness of Pavement Foundations for Heavy Traffic

Sir—Your correspondents in discussing pavement foundations have, I think, entirely missed the essential point and that is: An increase in the thickness of paving foundations over present American practice is a necessity as a protection to wearing surfaces and not to the base itself. A concrete foundation does not need to be badly fractured or shattered to be a failure in this sense; it is in the wearing surface that we must look for foundation failures.

The following are some of the reasons why heavy traffic streets in our cities should have pavement foundations thicker than 6 in.:

(1) The concrete in the base is not uniform in mixture or thickness, and, as laid in the street, its strength falls much below its theoretical value. The thinner it is laid the greater percentage of loss through dirt mixing with the bottom portion of the concrete, the subgrade soaking up the cement and water, and the greater the chances of rock pockets being formed. Even under the most rigid inspection, it is impossible and impractical to avoid these defects.

(2) If it were always possible to detect all the soft spots in the subgrade before the foundation is placed, the idea of thickening the concrete over them might work out. However, our city business streets have been so badly cut up that it is as cheap to thicken the whole base as it is to dig out each cut. Worst of all, the surface of the subgrade may appear uniformly compact and later develop many sunken spots, due to the bottom of an old trench settling, to leaky sewers or service connections or leaky water pipes.

(3) Temperature changes are greater in, and more seriously affect, a thin base than a thick one.

(4) Each wheel of a loaded vehicle is the center of an area of depression which is of considerable extent. The base is not rigidly supported at any point and the maximum deflection may be very appreciable without fracturing the concrete. This will vary with the condition of the soil and subgrade, width of street, weight of load, kind of surfacing and depth of foundation.

The amount of deflection for a given load has been measured by the U. S. Bureau of Standards on various kinds of pavement, and is appreciable on new cement-grouted stone block on 6 in. of portland-cement concrete base, and is very considerable on asphalt laid on a 4-in. base, or in the best forms of bituminous macadam. It is also probable that a cement-grouted brick surfacing, for instance, does not bend on the same curve as the base.

At any rate, the passage of a moving load is accompanied by a series of waves or undulations in the wearing surface, and in my opinion, this deflection or waving is great enough to seriously affect the wearing surface of a pavement subjected to the passage of large numbers of heavy vehicles, when the pavement is laid on a base of 6 in. or less of 1 : 3 : 6 concrete.

While such a statement may appear to be finely drawn, it is to be remembered that the effect of one load must

be multiplied by the headloads for each day and extended over a period of several years.

Owing to the numerous factors acting on the wearing surface, it is difficult to determine the effect of deflection except by comparing pavements subjected to similar conditions, but with different bases, over a period of years. The principle may be laid down that the more rigid the base the more nearly the wearing surface can be maintained to an exactly uniform grade, and thus be more enduring. Greater rigidity can be obtained more economically by increased thickness.

(3) The speed at which motor trucks move over streets demands a more massive foundation than one 6 in. thick. Loads moving over stone block, brick, manholes on a worn hard-rubber tire cause slight impact blows which are so rapidly repeated under a swiftly moving load that series of vibrations are set up in the pavement.

Where the pavement is slightly rough and on a thin foundation, these vibrations can be felt for some distance and are even carried through the earth to nearby structures. These vibrations are evidently a detriment to block pavements and must also affect the sheet surfacings.

A massive foundation will absorb these shocks. The more severe impacts where a heavy load drops into a sharp depression, off a high manhole or car track, soon shatter the base as well as the wearing surface. Such a condition, however, is generally due to faulty subgrade or construction.

In answer to the editorial inquiry as to the effect of impact on paving foundations, probably no base of good concrete 6 in. thick on a good subgrade is shattered where the wearing surface is maintained in good condition. I have seen weaker bases broken up where the surfacing had been allowed to deteriorate.

Impact does, however, seriously affect the wearing surface. Asphalt has practically no cushioning effect after it has been compacted by traffic and during the [illegible] months of the year. The block pavements on sand cushions do relieve the foundation by their cushioning and load-distributing effect.

(4) A review of the increase in wheel loads and traffic conditions on city streets during the last 15 years, as well as the present amount of poor or repaired pavement, should cause municipal engineers to look forward.

While one of your correspondents advises heavy rails, closely spaced ties, and 15 in. of solid concrete under and around the ties of street-car tracks to absorb vibrations and prevent destruction of the pavement, he considers a [illegible] foundation under the street pavement as a "wise precaution."

The fact of the matter is that motor-truck wheel loads are already approaching street-car wheel loads in amount and a motor truck does not run along a smooth steel rail, but is allowed any place on a more or less uneven surface. A pavement foundation which theoretically should be good for 50 to 75 years ought to be designed with the future in mind.

To protect our expensive wearing surface from [illegible], to maintain smooth easy riding pavements, to lessen the frequency, expense and inconvenience of repairs let us provide more rigid, more massive permanent foundations on the heavy traffic streets than has been customary. [illegible] thickness can be [illegible] sat but make 10 or 12 in. the maximum rather than 6 in.

CLARK R. MANDIGO,
Assistant City Engineer.

Kansas City, Mo., Oct. 28, 1914.

Broken Sprinkler Connections at the Salem Fire

Sir—The statements in the paper by Frank A. McInnes and Clarence Goldsmith, read before the New England Water Works Association at the recent meeting in Boston, Mass., with regard to the effect of broken sprinkler connections on the water pressure, are not altogether in accord with the facts. [See abstract, ENG. NEWS, Oct. 22, 1914.]

The breakage of the public water connection to the two sprinklered risks spoken of did not occur until about 3:30 p.m., nearly two hours after the fire started. And this breakage did not begin the demoralization of the fire-fighting service, that began one hour and forty-five minutes before. According to the report of competent engineers, the first fire company to get into action had to retire almost immediately. Another company tried to connect up a chuck hydrant a block away and finding it defective, had to beat a retreat. In the meantime, the fire burned without the least restraint. The day was hot and dry and the heat radiated by the fire was fearful. These conditions, of course, resulted in the opening of hundreds of sprinklers in the Keefe and Carr tanneries and they did not open in vain. These sprinklers contested the progress of the fire in the Keefe and Carr factories for a considerable period. The attack of the fire on these factories began between 1:40 and 1:55 p.m., and the riser pipes did not fall until about 3:30 p.m.

The authors of the paper overlooked the fact that there were many connections with the public water service other than the sprinkler connections. Five tanneries and leather plants were burned in Blubber Hollow. Two of them were sprinklered. All of them used water, particularly the tanneries—and tanneries use considerable water. These plants had regular service connections, some of them possibly as large as 6 in. These connections were independent of the sprinkler connections and added much to the wastage.

It is obviously stretching the imagination to charge that the difference between 8585 gal. and 2500 gal. per min. is due to broken sprinkler connections when numerous spouts from various broken and melted connections were to be seen after the fire had swept on its way.

Moreover, it is difficult to reconcile the statement that 2500 gal. per min. was the limit of the amount of water pumped, when there were 25 steam and gasoline-pumping engines at work in various sections of the city.

Other and competent engineers estimated that the maximum water consumption during the fire was at the rate of 17,750 gal. per min.

And what is more, the low pressure—the minimum was 10 lb. for one hour—was not the sole result of broken sprinkler connections. In a report on the Salem fire, Franklin H. Wentworth, Secretary of the National Fire Protection Association, says:

The [illegible] water-systems of Peabody, Danvers and [illegible] were already [illegible] the Salem system so fast that the [illegible] would shelter [illegible]

good. With water enough to raft Salem out to sea, her citizens on the borders of the fire zone threw away their garden hose and extinguished the sparks on their shingle roofs with tree-spraying outfits.

In the report of the Inspection Department of the Associated Factory Mutual Fire Insurance Companies is this comment:

There was apparently some hesitancy about turning in the higher pressures from surrounding towns until it was apparent that there was sufficient draft from the Salem mains so that the pressure would not build up.

Broken sprinkler connections should not be the "bone of contention" regarding the Salem fire. To be sure they broke and wasted water, but that was not a "lesson" of the Salem fire. The desirability of positive control of connections between public water-service mains and sprinkler systems in buildings cannot be gainsaid, but the arguments for this desirability cannot be strengthened by the happenings in Salem, for the building in which the fire began was not equipped with sprinklers and the pressure began to drop an hour and a half before the sprinkler connections broke. And the conflagration was burning blocks beyond the Carr and Keefe plants when the connections did break.

The one thing in the Salem water system reported excellent by the National Board of Engineers in 1907 was the spacing of gate valves. Why was it that an engineer of an organization of fire-insurance companies had to direct the closing of the sprinkler-connection valve at the Carr plant at 5 p.m., one hour and a half after the sprinkler risers went down? Surely there must have been valves in the public mains outside the fire zone which could have been closed.

Inspector Ames in his report to the Underwriters' Bureau of New England said: "*There was no time when the steamers lacked a water-supply.*" Evidently the breaks in the sprinkler-system connections did not hopelessly cripple the water service. And if the broken sprinkler systems had been immediately shut off and the pressure restored to normal conditions, what then? Franklin Wentworth answers the question: "Water from hose streams never yet stopped nor extinguished a conflagration."

And the fact will bear repeating that there would not have been any sprinkler-system breaks to talk about if the Korn factory had been equipped with automatic sprinklers.

I. G. Hoagland,
Secretary National Automatic Sprinkler Association.
80 Maiden Lane, New York City,
Oct. 26, 1914.

[Proof of Mr. Hoagland's letter was submitted to Messrs. McInnes and Goldsmith. Their reply follows.—Editor.]

Sir—In reply to the foregoing letter from I. G. Hoagland, we would say that our paper was written after an exhaustive study of the conditions obtaining during the first hour of the fire, the period with which we dealt. The officers of every engine company, numerous firemen and a number of others from whom reliable information could be had were interviewed. Information thus obtained was tabulated and only that which was corroborated by several witnesses was accepted.

Our data show conclusively that the three sprinkler pipes in question were broken within the first hour. If the evidence to this effect was not convincing it is inconceivable that buildings of so flimsy construction could survive for an hour under such exposure. Even if the buildings had remained standing and the pipes were unbroken, the systems would have discharged practically the same quantity of water through open sprinkler heads with equally disastrous effect.

Information was obtained in regard to all large service connections within the entire burnt area, and the only one broken in the area covered by the fire within the first hour was a single 2-in. The effect of the other services broken in this area was almost negligible.

We were not forced to exercise our imagination as the facts established by the test were sufficient to prove our point.

At the end of the first hour, ten engines only were at work and our information is conclusive that 2500 gal. per min. is a conservative estimate of their delivery. The figure used by Mr. Hoagland, namely, 17,700 gal. per min., represents the maximum draft during the fire and includes the waste from broken connections, steamer supply and domestic consumption. The fact that the minimum pressure of 10 lb. was not reached until the fire had been in progress nine hours is evidence of the large amount of water wasted.

The assumption that the waste through the three broken connections could have been stopped by closing valves in the public mains outside the fire zone evidences unfamiliarity with water-works systems and their operation.

If this could have been done it would have been necessary to close eight gates, two of which were on the large main feeding the district, with the result that the supply would not only have been withdrawn from many engines then working, but the entire western end of the city would have been without water-supply.

The writers were present during the height of the conflagration and were eyewitnesses to the fact that a considerable area of the city was entirely without water and that the engines even at the lower elevations were seriously handicapped on account of lack of pressure.

We are absolutely of the opinion that the flow of water through the connections to the Keefe and Carr plants practically destroyed the efficiency of the Salem water-works system, and are convinced that the size of such connections should be carefully restricted.

NOTES AND QUERIES

In the plan accompanying the retaining-wall failure described on p. 894 of our issue of Oct. 29, 1914, the direction indicated by the arrow as north is in reality west.

E. A. Little is Superintendent of the Engineering & Construction Department, United States Realty & Improvement Co., instead of R. K. Smith, as mentioned on p. 885 of our issue of Oct. 29.

An Employment Department has been established by the American Institute of Electrical Engineers. It is proposed to publish, in the monthly proceedings, announcements of positions open, records of men available, etc.

The Road Congress at Atlanta

The fourth annual Road Congress, conducted by the American Highway Association and allied organizations at Atlanta last week, attracted the largest attendance, probably, of any meeting for the discussion of highway improvement ever held in this country.

A large proportion of those at the sessions were county commissioners and county engineers from Georgia and other southern states, but there was also a large attendance of state highway engineers and city engineers in charge of street paving from every part of the country from New England to California.

At previous Congresses, agitation for Federal appropriations to build good roads has loomed large in the proceedings. This year the Federal aid question was kept in the background. At the afternoon session on the first day, which was supposed to be devoted to this topic, the Shackleford Federal Aid bill, which passed the House last spring but failed in the Senate, was generally condemned. On account of present and prospective financial conditions, it is generally realized that any considerable Federal appropriations for road construction are unlikely for some time to come.

A matter which figured more prominently in the Congress than Federal aid was the question whether state funds for road work should be expended on through routes or on radial roads from cities into the country to enable the farmers to reach a market. It is noteworthy that Fairfax Harrison, President of the Southern Ry., who was elected President of the American Highway Association at this meeting, presented a paper on Wednesday in which he declared that the first roads to be improved should be the roads connecting the farmer with the railway shipping point and the market and not the through routes so much desired by the automobile interests.

The Tuesday afternoon session was conducted by the National Civil Service Reform League and was intended to further the merit system in road organizations. The Chairman, Hon. R. H. Dana, and the speakers, Geo. R. Wales, Chief Examiner of the U. S. Civil Service Commission, and Arthur M. Swanson, Chief Examiner of the Philadelphia Civil Service Commission, vigorously supported the policy of selecting candidates by Civil Service methods for high appointive positions as well as for the lower positions.

Strong emphasis was laid by many speakers at different sessions on the desirability of supervising all the road work in a state through a state highway department. All but eight states have now in operation some form of state supervision, and these eight states, all in the South, are likely to create state highway departments next year.

A number of papers on various aspects of road construction and maintenance were read at the convention, and with the discussion upon them (of which the crowded program gave time for very little) will be later published in the Congress proceedings. Of these the most interesting and valuable to highway engineers generally was probably the paper by Col. Sohier, Chairman of the Massachusetts Highway Commission, giving detailed figures as to the cost of road maintenance in Massachusetts, and also in England and France. An abstract of this appears elsewhere in this issue. Another paper dealing largely with foreign practice was by Henry W. Durham, Chief Engineer of Highways of the Borough of Manhattan. Both these papers furnish most useful ammunition to the American engineer beset by a critic who holds the common idea that American engineers are fatally deficient in not copying foreign practice in street and road construction and maintenance.

The use of convict labor on public roads was a prominent subject in several papers before the convention, notably one by Geo. P. Coleman, State Highway Commissioner of Virginia, where 1700 convicts are worked on the roads the year round.

It is of interest to note that the emphasis in the good-road agitation which has been hitherto laid on road construction is now laid on road maintenance. Various speakers at the Congress urged that unless a large part of the money spent on road construction is to be wholly wasted, there must be first created an efficient organization which will see to it that the construction is done honestly and economically and that the completed road is continuously maintained.

The resolutions adopted by the Congress set forth that state-road departments and state aid are necessary to secure economy in highway construction; commend the work of the Lincoln Highway Association; recommend greater attention to the public safety by road officials; and urge that the Federal government undertake the construction of highways across forest and Indian reservations where necessary to provide links in through roads.

Road Maintenance Costs in France, England and Massachusetts*

By William D. Sohier†

French Roads

The French road system was established in 1826, and the total road system of 371,000 miles was built in about the next 25 years. The roads, practically uniform except as to width, have been built almost entirely of local macadam originally, 6 or 8 in. deep on a proper foundation. In resurfacing some of the main roads in later years, a harder stone and Welsh or Belgian granite have been used. The macadam surface of the road on the Routes nationales is 24 ft.; Routes departmentales, 18 ft., and the Routes de grande communication and d'interet commun, 15 ft.

The French engineers last spring contended that some 8000 miles of road ought to be resurfaced, using a tar macadam, because of the large increase in automobile travel around the cities, which travel was rapidly destroying their macadam roads, and they requested the Government to furnish $60,000,000 for that purpose, about $7500 a mile. The greatest problem for over fifty years has been maintenance. The roads are maintained practically by a central organization. The whole country is divided into 86 departments, and all of the county and rural roads within the department are managed by the prefet of that department and the expenditures appropriated by the council.

Direct charge is in the hands of a centralized body of competent engineers, about half of whom are graduates of the National School. Each department is divided into

*Excerpt of paper entitled "Road Maintenance," read before American Road Congress, Atlanta, Ga., Nov. 9-14, 1914.

†Chairman, Massachusetts Highway Commission, Boston, Mass.

four or five political districts, each district being called an arrondissement, and the roads are in charge of a district engineer, who is under the direction of the chief engineer. Each arrondissement is again divided into districts or cantons, and an assistant road engineer under the direction of the district road engineer looks after all the county and rural roads within the canton. Then comes the final subdivision, where the roads are divided into sections of a few miles long, taken care of by patrolmen. All of these are under civil service, and the men are promoted from time to time according to their ability.

Table I gives the approximate cost of maintenance on the French roads annually.

TABLE I. MAINTENANCE COSTS OF FRENCH ROADS

	Miles		Total Expense	Per Mile
Routes Nationales	23,800		$6,500,000	$273
Routes Departmentales	8,100	115,400	1,500,000	185
Chemins vicinaux				
Routes de grande communication	107,300		16,900,000	157
Route d'interet commun	47,500		6,000,000	126
Routes ordinaires	184,700		14,500,000	78

English Roads

In 1878 the cost of main roads was placed upon the counties. In order to even up the expense more or less the English government made appropriations to aid in the maintenance of these main roads, beginning in 1882 with an appropriation of about $800,000. In 1888 about $2,500,000 was appropriated, and now the Road Board has something over $6,000,000 annually which can be spent in improving the main roads. There is now a combination of the county taking care of the urban and rural main roads, with the parish and local authorities taking care of the rural roads. The main roads are something over 20% of all the mileage, leaving out London.

In almost all of the counties there are sections of road in charge of regular maintenance men. Most of the main roads in England outside of Metropolitan London and the other large cities are maintained by the use of tar. Some 40,000 miles of road were tarred in England last year, and some 6500 miles were built of tarred macadam. The system of maintenance now is not only to keep the roads constantly patched, but every year or twice a year the macadam roads are flushed and rolled, filling the holes and depressions first and adding a small quantity of chips and stone dust. On the tarred roads a section man keeps them constantly patched. They usually require a fifth or a sixth of a gallon of tar which is sprayed on once a year, and this is covered with pea stone or gravel and kept covered so it will not pick up. The tar is usually sprayed on under power.

Where there is heavy traffic the roads are being resurfaced with tarred Welsh granite, which is like our trap rock, or with tarmac, which is a tarred iron slag. There is also built a road of 3-in. stone, rolled hard, and grouted with a mixture of hot sand and hot tar, equal volume, poured into the road until it flushes it; then rolled in 1½-in. stone and smaller stone with a surface coat of tar and sand. The macadam roads with a tarred surface require retreatment every year. This costs about 2½ to 3c. per sq.yd. a year. The tar-mix roads require a new coat of a fifth of a gallon of tar applied on the surface every two years.

Average costs of road maintenance are given in Table II.

TABLE II. ROAD MAINTENANCE COSTS IN ENGLAND

County Councils:	Miles	Maintenance	Authorities County Engineers	Yearly maintenance per mile
Urban main roads	4,189	$4,601,790	61	$1100
Rural main roads	23,565	10,177,740		431
	27,754	$14,779,530		
County Boroughs	9,366	$6,437,380	28	$685
London Authorities	2,192	3,691,355	2	1680
	11,558	$10,128,735	30	
			Road Authorities	
Urban roads	11,411	$4,848,020	1733	$425
Urban roads	4,871	2,701,710		555
Rural roads	95,077	$11,562,920		122
	111,359	$19,112,650		
Totals	150,671	$44,020,915	1898	$290

The total expenditures per year, including improvements and interest, $75,990,000

Maintenance of State Highways in Massachusetts

Our Commission began building roads in 1894. The earlier roads were almost entirely macadam with a few miles of gravel or graded road. The standard road with necessary foundation and proper drainage wherever necessary was 15 ft. in width, water-bound macadam either of trap or local stone, 6 in. deep in the center and 4 in. on the sides, with a 3-ft. gravel shoulder on each side and with a ¾-in. crown to the foot.

The ordinary cost of maintenance is in Table IV, but up to 1907, when some of the roads were 12 years old, the cost of ordinary maintenance was substantially $100 a mile a year. Ordinary maintenance with us consisted merely of keeping the gutters, catch basins and drainage open and clean, cutting out the grass and brush on the roadsides, keeping the shoulders in proper condition, spreading a little gravel or sand on the road surface from time to time and filling the few holes or ruts that might occur with broken stone or gravel. Very few miles of road has been actually resurfaced prior to 1907.

In 1906, the automobiles began to come. Our roads were some of them 13 years old and only half the original depth of stone was left. We soon found that automobile travel, especially at high speed, tore up the macadam or gravel roads, especially on the curves, as soon as there were any considerable number, say 50 or more in a day. The traffic, of course, increased tremendously in the number of vehicles, because of the large mileage of the automobiles. What had been locally used country roads developed, between that year and the present year, into main through routes carrying oftentimes away out in the country on a main route over one thousand cars a day. Table III shows the increase in traffic from 1909 to 1912.

TABLE III. TRAFFIC CENSUS, 1909 AND 1912, MASSACHUSETTS

	1909 Census, 238.5 Stations			1912 Census, 156.5 Stations

Table IV gives maintenance charges of the state highways of Massachusetts from 1894 to 1913.

Starting in 1907 it will be noted that the cost for maintenance has risen by leaps and bounds from $158 a mile a year in 1907 to over $850 a mile a year in 1913, and it is still higher in 1914.

Our roads were rapidly going to pieces. We needed more money. We got the Legislature to double its ap-

propriation of $[illegible] a year and make it $250,000 for [illegible] year and $[illegible] a year since. We secured an increase in the automobile fees, and had four-fifths of that money available for the maintenance of state highways, and the other one-fifth for the improvement of [illegible] through routes in the towns. We found that our old roads were being destroyed by the rapidly increasing amount of automobile travel. The traffic on the roads had increased from [illegible] to 40 times in volume.

TABLE IV. COST FOR REPAIR AND MAINTENANCE OF STATE HIGHWAYS FROM 1893 TO 1913, MASSACHUSETTS

	Repair and Maintenance			State Highways	
Year	Cost	Miles	Av. Cost per Mile per Year	Miles Built	Cost of Construction
[illegible]				[illegible]	
[illegible]				[illegible]	$[illegible]
[illegible]	$4,7[illegible]	40.1[illegible]	$[illegible]	57.92	[illegible]

*[illegible] Fund.

Today [illegible] of all our state highways that have not been resurfaced have been coated and kept coated with some bituminous material and have been kept constantly patched. Where heavy hot oil was used, it has lasted in some instances for five years, carrying a large amount of automobile travel but a small amount of heavy teaming. Under many heavy teams it has failed in a month or two. We have then used a light oil to lay the dust and prevent the automobiles from tearing the road up, and have left the stone to carry the travel until we could resurface the road.

Because of the automobile traffic on many main routes, we are now [illegible] to put [illegible] a bituminous top 2 to 3 in. deep. We have used refined tars in both the mixing and grouting method. We have used asphalts with the same methods, and we believe that use is economical and necessary on any roads that have more than fifty automobiles a day and where there are more than fifty loaded teams.

In Table V is shown the class and character of surfaced roads that we believe will stand traffic of a certain class, kind and character.

Certain exceptions to Table V should be noted. Army [illegible], especially large bodies of cavalry and artillery, will rapidly destroy any bituminous blanket surface. A blanket coat of hot oil on macadam will cause a much larger number of teams if there is a [illegible] of two to three automobiles or [illegible] to each team to keep the bituminous surface constantly rolled down when the hoofs and teams pick it up. A very few teams, or [illegible] at a few very heavy teams every day, will destroy the surface if the load is heavy enough to shear down

TABLE V. COMPARATIVE VALUE OF ROAD SURFACES

(Result of observations of traffic on different types of road surfaces in Massachusetts. Standard road, 15 ft. in width, gravel or waterbound macadam 5 to 6 in. in thickness with adequate drainage and proper [illegible], with 3 ft. gravel shoulder on each side.)

AVERAGE DAILY TRAFFIC

	Light Teams, Carriages, Wagons	Heavy Teams, 1-Horse	Heavy Teams, 2 or more Horses	Automobiles
A good gravel road will wear reasonably well and be economical with	50-75	25-30	10-15	50 to 75
Needs to be oiled with	50-75	25-30	10-15	Over 75
Oiled gravel, fairly good heavy cold oil, ½ gal. to the sq.yd., applied annually with	75-100	30-50	20	500 to 750 or more
Waterbound macadam will stand with	175-200	175-200	60-80	Not over 50 at high speed
Cold oil or tar will prove serviceable on such macadam with	175-200	175-200	60-80	50-500
Macadam will then stand but the stone wears, of course, with	175-200	175-200	60-80	500 or more
Waterbound macadam with hot asphaltic oil blanket will be economical with	100-150	50-75	25-30	1500 and [illegible] with [illegible] teams
And stand at least		[illegible]	[illegible]	50 trucks
But will crumble and perhaps fail with over	150	75	30	
(On narrow tires, ice, farm and wood teams, etc.)				
Waterbound macadam with a good surface coating of tar (½ gal. to the sq.yd.) will stand with	100-150	50-75	25-30	1500 or more
but requires to be recoated annually with ¼ gal. of tar per sq.yd.				

It is assumed that all road surfaces are kept constantly patched, that before applying bitumen the road surface is cleaned and patched, and the bitumen covered with pea stone and sand or gravel and kept covered so that it never picks up.

entirely through the surface to the stone. If this process is repeated once or twice a day, a rut soon develops and the road becomes muddy and the bituminous surface rapidly disintegrated.

Ordinary maintenance, which has consisted of keeping the drainage open, shoulders cut back, and the road sanded, with slight patching, has averaged about $100 a mile a year. Where the road can be maintained with light oil, the additional cost is about $250 a mile a year, or $350 a mile a year in all. The cost of heavy oil or tar on the surface where it is suitable to use it because it will stand the traffic, is about twice the cost of the light oil in the first instance, and with the patching and all that is necessary it will cost about the same figure, or about $250 to $300 a mile a year, this being on a five-year basis.

In resurfacing our roads with 2- to 3-in. bituminous macadam top, the cost has varied from about 50c. per sq.yd. for a 1½-in. top, no stone being larger than 1¼ in., and 1¼ gal. of tar sprayed into it, to $1.10 a sq.yd. for a 3-in. top, made of 2½-in. stone, either mixed or grouted with a good grade of asphalt. The tar-sand grouted macadam has cost from 90c. to $1 per sq.yd. We believe that the roads of this character will have a very small maintenance cost outside of the ordinary maintenance for a period of from eight to twelve years.

Lack of Uniformity in Notation is the cause of no little trouble to engineers in studying theoretical problems. One phase of this question was recently discussed as follows by a speaker before the Concrete Institute in London:

One of the greatest causes of difference in notation is the blind copying of symbols by persons who really do not know what is the origin of a given symbol. In fact, it has been suggested by some brilliant student that people only used algebraic symbols when they did not know what they were talking about, and there certainly seems a great deal of truth in that remark. Another cause of the growth of chaos and deterioration of notation is that when books are translated from a foreign language it may be that the author is not a mathematician—he may be merely a linguist—for he frequently translates the words and leaves the letters in their original form, and the books lose a great deal of their utility. I would ask that if books are to be translated they should be translated by engineers or by mathematicians or by competent persons able to convert the notation into the [illegible].

Emil Kuichling

By Allen Hazen*

Emil Kuichling died suddenly in New York City, Nov. 9, of apoplexy. Although he had lived in New York City for the last fifteen years and much of his best known work had been done there, yet his memory will always be associated with Rochester. In his long previous residence in Rochester, his connection with the water-supply and sewerage systems of that city, first, as Assistant in the Water Department for twelve years, then as a member of the Executive Board for two years, and, after an interval, as Chief Engineer for nine years, and more recently, as Consulting Engineer, he did more than it is often given to one man to do for a city in providing it with a good and ample water-supply and a proper system of sewerage and sewage disposal.

When he gave up the position of Chief Engineer of the Rochester Water-Works and moved to New York, one of the daily papers said of him:

In every capacity his daily course has had four characteristics—absolute integrity, tireless industry, zeal for the public good, professional honor. He had the rare quality of command of detail combined with a broad conception of general principles and far-reaching results.

This unusual tribute to a retiring city official was as unusual as it was gratifying.

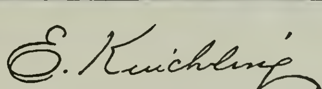
He had an inquiring mind. He was always looking for an explanation of the unexpected happenings in his daily life and work, and in his search for answers he had a remarkable faculty of knowing where to look and of scrutinizing the work and experience of others, and of making it contribute to the explanation.

His ample library was useful to him to an extent rarely reached by engineers. He never spared the midnight oil and seldom forgot, and his mind was loaded with orderly and available memories of the experiences and trials, successes and failures in the line of his chosen work. No one could think of so many reasons why a proposed structure would be weak or would fail in its intended work, or could cite the precedents for it, successful and otherwise, more surely and accurately.

His views as to the merits and defects of works and designs that he examined were bluntly conveyed when occasion demanded, in language so clear that the exact meaning could never be for a moment in doubt. This often led to the feeling that he was severe and too pessimistic about new ventures, but to those who knew him well, and could face the force and vigor of his criticism, he was helpful to an extent that it is hard to indicate adequately.

He was a man who thought vigorously and well, and who made others think for themselves even when they did not wish to think. By his own work in design, by his criticism of the work of others, and by his influence upon the many engineers with whom he came in contact, he contributed directly and indirectly to the sound, safe and durable design of American water-works structures, and his influence will extend far beyond the works with which he was directly connected.

It is interesting to inquire how such men are trained and produced. The answer must often be unsatisfactory because the influences that were strongest in the boy and the young man are not the ones that are best known to those who come after; but in Mr. Kuichling's case may be noted the practical experience of a thirteen-year-old boy with a master builder, the busy summer vacations of the school life always devoted to engineering work, the ample and broad education, first, at Rochester University, and afterward, beginning at the age of 22, at the Technical School at Karlsruhe, Germany, followed by the twelve-year-long drill as Assistant to a strong and able chief, the late J. N. Tubbs, in which there were ample opportunities for study of the qualities of men as citizens, as politicians, as contractors, as chiefs, and as assistants, as well as of the simpler qualities of the masonry, metal and water that were the more direct objects of his work. Experiences during this time led to the drafting of new specifications and contracts to meet local troubles. These were models of expression, always being definite and clear. No paragraphs from specifications have been copied and used more widely than these.



Mr. Kuichling was born at Kehl, Germany, in 1848, came to Rochester as an infant with his father, Dr. Louis Kuichling, and spent the greater part of his life there. He graduated at Rochester University in 1868, and at the Technical School at Karlsruhe, in 1872. He was connected with the Rochester Water-Works as Assistant Engineer for twelve years, from 1873 to 1885, as a member of the Executive Board from 1885 to 1887, as Chief Engineer from 1890 to 1899, and more recently as Consulting Engineer. He also played a most important part in developing and designing the sewerage and sewage-disposal systems of that city.

For many years, while at Rochester, he acted as engineering adviser of the New York State Department of Health. He acted at one time as hydraulic engineer for

*Consulting Civil Engineer, 30 East 42nd St., New York City.

the barge canal, and also conducted, while still at Rochester, a growing advisory practice in water-works and hydraulic matters. Since Jan. 1, 1900, he had lived in New York City, and had continued this practice actively, and as it had aided in the development of water-supplies and water powers all over the country.

With simple tastes and habits, Mr. Kuichling early learned from his parents the rare art of graceful and delightful entertaining, and he was indeed fortunate who experienced the full measure of his hospitality.

He was a member, and had been a Director and Vice-President, of the American Society of Civil Engineers, and had been President of the Rochester Engineering Society. He was also a member of the American and the New England Water-Works Associations, of the American Public Health Association, the Engineers' Club, and of the Masonic Orders.

Among Mr. Kuichling's numerous technical writings a few technical society papers and professional reports may be mentioned:

American Society of Civil Engineers—(1) The Relation between the Rainfall and Discharge of Sewers in Populous Districts. 1889. (2) Loss of Head Resulting from the Passage of Water through a 24-Inch Stop Valve. 1892. (3) The Financial Management of Water-Works. 1897.

New England Water-Works Association—Steel Pipes for Water-Works. 1910.

Professional Reports—(1) Report on the Water Supply of the Proposed Enlarged Erie Canal, 1901. (2) Report on the Disposal of the Sewage of the City of Rochester, 1907.

Mr. Kuichling married Sarah Louise Caldwell in 1879, and she survives him.

Resolutions on the Death of Emil Kuichling

The following resolutions on the death of Emil Kuichling were adopted by the Rochester Engineering Society, of Rochester, N. Y., on Nov. 14, 1914:

Whereas, Emil Kuichling, one of the founders of this Society and its first Chairman, was suddenly taken from us, Nov. 9, 1914, while still in the active practice of his profession; therefore, be it

Resolved, That we, the members of the Rochester Engineering Society, hereby express our appreciation of his notable qualities, which were known to most of us by reputation and to many of us by long personal contact with the man and with his work.

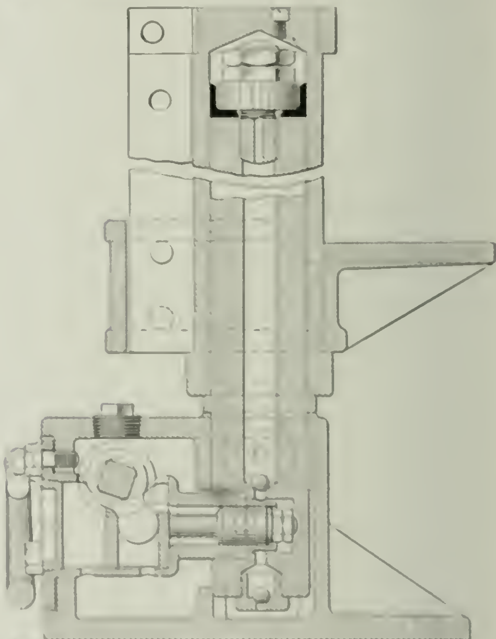
He was a master of detail, a profound student, a tireless investigator and an indefatigable worker, and [illegible] to record, with the greatest care, the results of his investigations, observations and studies.

[illegible]

A Hydraulic Jack for Emergency Service

The unique design of hydraulic jack shown in the accompanying figure was first evolved for electric-railway emergency service (according to the requirements of the Pennsylvania Public Service Commission), but has certain obvious advantages for shop and field use.

The pump (horizontal) and plunger (vertical) are fixed to the base and the cylinder rises, carrying with it an adjustable claw which can be swung through 360° without shifting the jack and which can be set at the most convenient initial height. This arrangement allows the pump handle to be worked from the most accessible position in each case. The handle is curved and the socket has four holes so that the pump can be worked from either above or below or from either front or back.



The Watson-Stillman Emergency Jack

The pump plunger is packed with leather rings between compression glands; the ram plunger has a single cup packing. The valves are simple balls and the oil under pressure flows up through the ram piston and packing [illegible]. For release, a needle valve on the side opens a passage from the [illegible] to the reservoir in the base. An "no-freezing" mineral oil is used, as this has been found to cause no appreciable deterioration of the packing and does not congeal at the temperatures met with in emergency service.

The jack described is made by the Watson-Stillman Co., of New York. Two sizes, five and ten tons, are being put out at present. With each size a 175-lb. man can exert the maximum lift for which the ram is intended. The stroke is 10 in. in both sizes and the parts are proportioned for 50% overload.

NEWS NOTES

Explosions Wrecked Dye Works—The plant of the W. Beckers Aniline & Chemical Works, Brooklyn, N. Y., was destroyed by two heavy explosions resulting from experimentation. A young chemist was killed and 50 other men were injured. The damage was estimated at about $100,000.

The Houston Ship Channel, which provides a 25-ft. depth from the Gulf to Houston, Tex., was formally opened on Nov. 10, by President Wilson pressing a button in Washington, which fired a signal in Houston. The channel was described in "Engineering News," July 13, 1914, p. 188. Wharves, docks and other port appurtenances have not been completed, but a bond issue of $3,000,000 has been approved for that purpose.

Bids for Repair of Moodna Siphon, Catskill Aqueduct—The bids for driving a shaft about 400 ft. deep and a section of tunnel 900 ft. long, to supplement the existing Catskill Aqueduct at Storm King, have been received. The five lowest are as follows: Oscar Daniels Co., $365,926; T. A. Gillespie Co., $382,290; Mason & Hanger Co., $387,499; Pittsburgh Contracting Co., $389,207; J. F. Cogan Co., $394,816. This work was discussed in our issue of Nov. 5, p. 954.

The Club House of the Cleveland Yacht Club is being moved seven miles by means of three scows. It is a 2½-story frame structure, 50x70 ft. in plan. The contractor is G. Alexander & Sons, Movers, and it is understood that the water transportation will be effected by the American Construction Co.

An Ambitious Dock Scheme on Lake Erie at Cleveland, Ohio, has been proposed by O. C. Barber, the Cleveland match manufacturer. The plan contemplates extensive ore, coal and merchandise docks on the lake front between East 55th St. and East 67th St., and a four-track subway connecting the dock and warehouses with the Cuyahoga Valley some miles south, where there would be about eight miles of track frontage for manufacturing sites. The scheme is estimated to cost about $9,000,000. Just at present there seems to be no immediate prospect of its being carried out, and furthermore, it is in violation in some respects of the federal government's scheme for developing the lake front at Cleveland.

The New Refuse Incineration Plant for San Francisco, described in our issue of Jan. 15, 1914, was recently subjected to a 30-day test under the direction of M. M. O'Shaughnessy, City Engineer. On Nov. 14, Mr. O'Shaughnessy reported that the incineration was imperfect, the smoke excessive and that other defects existed. He also reported that the cost of incineration during the test was $1.33 per ton, which is about 20% above the guarantee. He recommended that the city reject the plant and enter suit for the return of the money already paid to the contractor, the Destructor Co., of New York City. This recommendation will come up for action by the Board of Supervisors of San Francisco on Nov. 23.

A Diversion of the Little Calumet River, south of Chicago, is proposed in connection with a land drainage and reclamation project known as the Burns Ditch project. The river now discharges into Lake Michigan at South Chicago, but the diversion channel will discharge at Tolleston, Ind., and will take the water from about 50% of the drainage area of the river, thus reducing the floods which now occur along the river in Illinois. It is considered that this will benefit the drainage problem of the Sanitary District of Chicago, which is now building the Sag Canal from the Calumet region to the main drainage canal. The new ditch would take the water coming from the rural districts, and thus tend to decrease the amount of pollution that is scoured up and discharged into the lake at South Chicago by every moderate flood. The Burns Ditch project is now in the courts, as it is to be paid for by special assessment.

Channel Clearing on the Kaw River—The Board of Directors of the Kaw Valley Drainage District, Wyandotte County, Kansas City, Kan., is contemplating the cleaning out of the Kaw River channel from its mouth to a point at least six miles above same. This work embraces the removal of all solid obstructions such as piling, jetties, rock, box-cars, car tracks, etc., and the removal of dirt lying between levees to a depth of at least 30 ft. below the tops of same. This amounts to approximately one million yards. The Board of Erection contemplates the removal of the dirt by means of a hydraulic dredge discharging on top of and behind the levees at points determined by the Board. The United States Government has reported on the removal of the solid obstructions. The report states that wherever said obstructions might be identified as belonging to any of the railroads, the stock yards company or the various packing companies, the cost of the removal should be charged to said company; the cost of the removal of the unidentified obstructions to be borne equally by the Drainage Board and the Government.

The Largest Automatic Sewage Pumping Station in the World, with a total capacity of 151,000,000 gal. per 24 hr., is now being built by the Public Works Department of Boston at Union Park and Albany St. The sewage will reach the station through a 7 ft. 4 in. by 4 ft. 10 in. sewer, passing through a 15x29-ft. screen chamber to the pump suction well and will be raised about 13½ ft. into a 5 ft. 9 in. by 5 ft. 3 in. force main. Four pumps will be installed, three having 36-in. suctions and 36-in. discharges to deliver 30,000 gal. per min. each, and one having a 26-in. suction and 24-in. discharge to deliver 15,000 gal. per min. The larger pumps will be driven by 150-hp. constant-speed motors, operating on a 440-volt circuit and the smaller pump will be driven by a similar 75-hp. motor. Each pump will be equipped with an air-relief valve, pressure gage, recording tachometer and a 2½-in. gate valve with hose coupling nozzle for flushing. The automatic control is obtained by a float, moving in a 24-in. control-float well, which will actuate a multipoint switch on an independent switchboard. This switch will close five circuits consecutively as the elevation of the sewage in the suction chamber changes. The first circuit energizes the operating winding of the magnetic switch which connects the transformers across the line. The other four circuits control the pumps. The superstructure of the pumping station will be 40x65 ft. and will contain an office, shop, transformer room and motor room.

PERSONALS

Mr. Dorsey J. Parker, of Alabama, has been appointed mining engineer in the Bureau of Mines, Pittsburgh, Penn., and his appointment has been approved by the Secretary of the Interior.

Mr. William T. Sitt, Assoc. M. Am. Soc. C. E., who was connected with Wells Bros Co., of New York City, for the past 12 years, retired from the active service of the company on Oct. 1, and has taken up private practice, specializing in the design and construction of foundations and buildings.

Mr. M. Z. Richards, Land and Industrial Agent of the Southern Ry., has been appointed Commissioner of the Industrial and Agricultural Department recently formed by consolidation of land, industrial, farm improvement and livestock departments. Mr. Richards has been in railway service since 1881.

Mr. Robert Sayre Kent is President of Robert Sayre Kent, Inc., Engineers, recently formed. The new concern will continue Mr. Kent's former business—designing, superintending and operating sugar factories and refineries, iron foundries, etc.—and will have offices at the old address (50 Court St., Brooklyn, N. Y.).

Messrs. Frank A. Randall, Assoc. M. Am. Soc. C. E., since 1912 Chief Engineer of Morey, Newgard & Co., Chicago, and William H. Warner, structural designer with Graham, Burnham & Co., Chicago, have opened an office for the practice of civil and structural engineering in Chicago, under the firm name of Randall & Warner.

OBITUARY

Orlen W. Sealand, Superintendent of the Sun Oil Co., of Toledo, Ohio, was overcome by carbon-monoxide gas at the plant, on Nov. 11, and died from the effects on the same day. Mr. Sealand was graduated from the Case School of Applied Science in 1904.

Louis M. Clement, M. Inst. C. E., a well known West Coast civil and mechanical engineer, died Oct. 29, at his home, Hayward, Calif. He was an engineer on construction work for the Central Pacific R.R. in 1861. Later he designed and built the Hayes St. cable railway in San Francisco and other street railways in that city and Oakland. He was for many years Consulting Engineer of the Southern Pacific Co. He was born in Canada in 1837 and went overland to California in the days before transcontinental railways. He was a former member of the American Society of Civil Engineers, the American Society of Mechanical Engineers and the Canadian Society of Civil Engineers.

Daniel A. Camfield, a contractor of Greeley, Colo., died in New York City, on Nov. 10, as the result of a stroke of ap-

[illegible] years old and for [illegible] in the West, [illegible] large irrigation contracts. He was the [illegible] of a newspaper in Greeley and was interested in the [illegible] Water Co.

[illegible] C. Barnes, M. Am. Soc. C. E., a prominent civil engineer of Jamestown, N. Y., died there Oct. 29, after an illness of more than a year. He was born in New York [illegible] In his youth he attended the [illegible] Preparatory School, Detroit, Mich., where he prepared for the civil engineering course at the University of Michigan, graduating from the latter institution in 1868. After graduation he engaged in railway construction in Iowa and Illinois in positions ranging from rodman to chief engineer until 1871, when he assumed charge of the construction of the Pittsburgh, Bessemer & Lake Erie R.R. as Chief Engineer. In 187[illegible] he supervised the construction of the Buffalo & Southwestern R.R. from [illegible] to Jamestown. From 1877 to [illegible] he was United States Assistant Engineer on river and harbor work, and was engaged in the construction of the Sault Ste. Marie canal, the repair of the St. Clair canal, and the dredging of the Livingston channel in the Detroit River. Since [illegible] he has resided at Jamestown, serving for several years on the Board of Public Works, and has many times been engaged as consulting engineer for the city. He was one of the commissioners for the drainage of the Cinewango swamp and was the engineer of this important work. For thirty-[illegible] years E. C. Barnes was an active member of the American Society of Civil Engineers.

ENGINEERING SOCIETIES

COMING MEETINGS

AMERICAN SOCIETY OF REFRIGERATING ENGINEERS
Nov. [illegible]-Dec. 1. Annual meeting at New York. Secy., W. H. Ross, 154 Nassau St., New York City.

AMERICAN PUBLIC HEALTH ASSOCIATION
Nov. 30-Dec. [illegible]. Annual meeting at Jacksonville, Fla. Secy., Prof. Selskar M. Gunn, Massachusetts Institute of Technology, Boston, Mass.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS
Dec. 1-4. Annual meeting at New York City. Secy., Calvin W. Rice, 29 W. 39th St., New York City.

AMERICAN INSTITUTE OF ARCHITECTS
Dec. [illegible]. Convention at Washington, D. C. Secy., D. Knickerbocker Boyd, The Octagon, Washington, D. C.

ASSOCIATION OF AMERICAN PORTLAND CEMENT MANUFACTURERS
Dec. [illegible]. Annual meeting in New York City. Secy., Percy H. Wilson, Bellevue Court Bldg., Philadelphia, Penn.

AMERICAN MINING CONGRESS
Dec. [illegible]. Annual meeting at Phoenix, Ariz. Secy., J. F. Callbreath, Denver, Colo.

NATIONAL SOCIETY FOR THE PROMOTION OF INDUSTRIAL EDUCATION
Dec. [illegible]. Convention at Richmond, Va. Secy., C. A. Prosser, 140 W. 42d St., New York City.

SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS
Dec. [illegible]. Annual meeting at New York City. Secy., D. H. Cox, 29 W. 39th St., New York City.

AMERICAN ROAD BUILDERS' ASSOCIATION
Dec. [illegible]. Convention at Chicago, Ill. Secy., E. L. Powers, 150 Nassau St., New York City.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS
Dec. [illegible]. Annual meeting at Chicago, Ill. Secy., F. M. White, Madison, Wis.

National Society for the Promotion of Industrial Education—The eighth annual convention of the Society will be held in Richmond, Va., Dec. [illegible], with headquarters at the Hotel Jefferson. The National Vocational Guidance Association will hold its annual meeting in the same city, Dec. [illegible]. The [illegible] program of the Society has been prepared and can be obtained from the Secretary, C. A. Prosser, 140 West 42d St., New York City.

Society of Naval Architects and Marine Engineers—The [illegible] general meeting of the Society will be held in the [illegible] Building, New York City, Dec. [illegible], beginning at [illegible] each day. The annual banquet will be held [illegible]. The [illegible] list of papers includes the following: [illegible]

[illegible] Wentworth, "[illegible] of Warships at Sea;" Spencer Miller, "The Behavior of Riveted Joints under Stresses;" James E. Howard, "The Present Status of Marine Internal-Combustion Installations;" W. R. Haynie, "The Application of Electric Propulsion to Battleships, together with the Experience Gained in the 'Jupiter';" Lieut. S. M. Robinson.

New England Water Works Association—At the first monthly meeting of the 1914-15 season, held in Boston, Mass., Nov. 11, two interesting and instructive papers were presented on the two newest methods of sterilizing water-supplies. Dr. Max von Recklinghausen described the sterilization of water with ultra-violet rays, beginning with an outline of the principles involved, including many results of the author's experiments and experience with French installations, and ending with a statement that several large installations were under consideration in this country. The paper was very optimistic in its conclusions on the efficiency of this method of water purification. Sheppard T. Powell's paper on the use of ozone as a sterilizing agent was read, but in the absence of the author was not discussed. This paper gave an interesting and valuable summary of American experience in the use of ozone, discussing particularly the difficulties and the causes of failure in many installations. The paper gave in some detail the changes which have been made in the Ann Arbor, Mich., plant and the results of experiments there and elsewhere, both in removal of bacteria and of color and odors, together with cost data. Mr. Powell's conclusions were, that ozone was an efficient means of removing all three of these objectionable features in water, but he recognized at the same time that it was not a cure-all; that former failures with ozone as a disinfecting agent were due to want of perfection in mechanical details and operating methods. On the whole, this paper was very optimistic on use of ozone as a water-sterilizing agent. The topical discussion on the general subject of service pipes was long and interesting and many water-works officials of long experience took part. This discussion covered little more than the kind of pipe to use; other branches of the subject will probably be taken up at other meetings. Lead pipe seemed to be the prime favorite, and it was stated that objections to it were in many instances æsthetic rather than founded on any real danger in its use. Cement-lined iron pipe was next in popularity and several instances were given of very satisfactory results with galvanized-iron pipe.

Conference of American Mayors on Public Policies as to Municipal Utilities—A large gathering of mayors and others interested in the regulation of public utilities was held in Philadelphia on Nov. 12 and 14, 1914. The conference was called by the following mayors: Rudolph Blankenburg, Philadelphia; John P. Mitchel, New York; Carter H. Harrison, Chicago; Newton D. Baker, Cleveland; [illegible] W. [illegible], Dayton. At the two evening sessions, the mayors and delegates were the guests of the American Academy of Political and Social Science.

There were numerous addresses on state and local legislation of public utilities, municipal ownership and operation, both in theory and practice, and municipal home rule. The sentiment of the conference seemed to be almost wholly in favor of municipal ownership, qualified chiefly [illegible] conditions of local expediency. There was also expressed much strong feeling against state and in favor of local regulation of public service corporations, but this was tempered with considerable recognition of the fact that utility regulation is largely a matter of state concern, and, except for the larger cities, [illegible] problem for [illegible] communities. [illegible] objections were voiced against state regulation of municipally-owned public utilities, but this view was not accepted by all the members.

At the end of the conference a Committee on Recommendations, of which Mayor Baker of Cleveland was Chairman, reported as follows: (1) No stand should be taken for or against municipal ownership, but it is highly important that every municipality have a free hand in this matter. (2) No stand should be taken on state as against local regulation of privately-owned utilities, but all franchise grants should be [illegible] and municipally-owned utilities should be subject to local control only. (3) The [illegible] of The Utilities Bureau should [illegible] with its [illegible] keep records, employ experts and render service to individual cities. This report was adopted.

It may be added that The Public Utilities Bureau has as its [illegible] the [illegible] named above, and [illegible] Frederick A. Cleveland, Director of the New York Bureau of Municipal Research; [illegible] W. [illegible], consulting engineer, [illegible]; and Chas. R. Van Hise, President of the University of Wisconsin, Madison, Wis. The [illegible] office of the Bureau is [illegible] City Hall, Philadelphia, Penn.

Engineering Literature

CONTENTS

CORRESPONDENCE

A Card-Index Multiplication Table

Sir—I read Mr. Rossiter R. Potter's article on "Cox's Commercial Calculator" in your issue of Oct. 15 with much interest, as I abandoned that system after doing a large amount of work on it in favor of a system which I patented in 1910.

F. C. Williams.

Commercial Bank Building,
Cleveland, Ohio, Oct. 29, 1914.

[From a pamphlet sent by Mr. Williams it appears that his "Multiplying Device" is "simply a large multiplication table," in card index form. Products up to 9×999 can be read directly. Beyond that simple multiplication followed by addition is required.—Editor.]

On Methods of Instruction in Surveying

Sir—I note the criticism on the expediency of teaching surveying by the use of worked-out problems, in the review of my book, in your issue of Aug. 14. You said:

> Is it better to tell a young man what you want done and leave it to his initiative and ingenuity to devise the best ways and means, with the help of necessary text-books and verbal instructions, or to give him a cut-and-dried problem and say, go thou and do likewise? To help train a real engineer, we would prefer the former.

In defense of the above criticism, I wish to state that the "Field Manual of Plane Surveying and Railroad Curves" is intended to be the A B C of Plane Surveying. It is designed to help the student at a time when he not only has to learn the form of report, but also the principle of the problem. By placing a few well selected fundamental problems at his convenience, he is started in the right direction without an excessive amount of personal supervision; that is, he is able to help himself in the early stages of the work by this convenience.

After he has completed these first few problems in plane surveying, he takes up the second and third terms of surveying without any assistance except what he can get from the standard text or his instructor. He is then thrown upon his own resources to make notes to suit the problem he has in hand. We have tried this test for two terms and have found it to give the results that were expected.

If the above criticism can be applied to this text it may also be applied to a number of other texts which have been successful. The only difference between this and other manuals is the matter of convenience. The others have their field notes photographed and printed along with detailed instructions about apparatus and method of procedure.

If the field book is used, it is necessary for the student to carry both manual and field book to the field, which is inconvenient. The student is also expected to buy and read a reference work. The expense of these three books is too large when we consider the fact that he is paying for the same instruction three times. The reference book gives it to him once and the manual twice (first in the form of instructions as to apparatus and method, second in reproduced field notes). If the problem is reviewed in class, he receives the same instruction four times. The purpose of the Field Manual is to eliminate one of these repetitions, by combining the necessary part of the manual and the field book, which reduces the expenses and adds greatly to the convenience of the student. At Valparaiso University we have saved every student \$1.50 on his plane surveying book bill and he has just as much for his money.

It is our policy to encourage a man's initiative and ingenuity to devise the best ways and means to do his work, and this is done in due time, but in the beginning of a subject it is necessary to teach him some form or convention in which there is no opportunity for initiative or ingenuity. Just as soon as the work advances to a stage where a variety of form is possible, we give him the opportunity of making for himself his own plan.

R. C. Yeoman.

Valparaiso, Ind., Nov. 5, 1914.

[The author shows the reason for using the kind of field book we have criticized when he says it answers the purpose "without an excessive amount of personal supervision." In other words, he uses the book for exactly the purpose we suggested. It seems to us that any young man who has a fair knowledge of geometry and trigonometry does not need to exercise any great amount of ingenuity to work out and keep the notes of simple surveying problems, if he is given a very moderate amount of verbal instruction, with what he can glean for himself from standard textbooks. It is not a question of easing the work of the instructor, but of making a surveyor.—Editor.]

REVIEWS AND NOTES

A Brief Text on Foundations

REVIEWED BY C. S. RINDSFOOS*

FOUNDATIONS: A Short Text-Book on Ordinary Foundations Including a Brief Description of the Methods Used for Difficult Foundations—By Malverd A. Howe, M. Am. Soc. C. E., Professor of Civil Engineering, Rose Polytechnic Institute. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6x9 in.; pp. vii + [illegible]; [illegible] text figures. $1.25, net.

It is curious to note that foundations, so long neglected, have become, all at once, a popular subject for the authors of textbooks. Within the past few months, three such books have appeared. In a previous review of one of these, the writer made the criticism that too large an amount of matter had been crowded between one set of covers, and that a division into two volumes would have produced greater convenience. In the book which is the subject of the present review, the opposite extreme prevails. The material is so abbreviated that its use will be found to be quite limited.

The author announces that "the object is to state in an elementary manner the fundamental principles upon which the proper design of foundations is based," and again that "an attempt has been made to so present and arrange the subject matter that the book can be successfully used as a textbook." With these things in mind, the fact that the work is so small is at least understandable, and yet it is hard to see wherein the book will offer any advantage over one of the more complete texts which have appeared previously, unless it be in the matter of cost to the student who will use it, or unless it has been arranged to fit a certain course in a particular college.

The book is divided into six chapters, as follows: Supporting capacity of soils; wall and column footings; piles and pile foundations; chimneys and towers; bridge piers and abutments; and methods employed for difficult foundations.

Many formulas are given for the design of different types of foundations, as well as examples under each topic, the answer in each case being stated.

With one or two exceptions, nothing is presented on any of these topics that had not already appeared in book form several years ago. The descriptions are so brief that the elementary student would not be greatly benefited unless there be amplification in the form of lectures or other reading. Many references to other books and to current periodicals are included for this purpose, and this feature deserves commendation.

In conclusion, it should be said that the book is elementary, concise and will be of some use to the student—though a monograph on so broad a subject can be of but doubtful value.

REPORT ON EUROPEAN PAVEMENTS—By George W. Tillson, Consulting Engineer to the President, Borough of Brooklyn, New York City. [illegible] Paper; [illegible]; illustrated.

The author gives, in narrative form, a description of the kind and condition of the pavements in a number of European cities, as observed by him in the summer of 1913 while abroad as official delegate of the City of New York to the International Road Congress. About 100 illustrations, extracts from specifications, and cost data are also included.

Mr. Tillson concludes that the general condition of pavements in European city streets is better than that of the streets of American cities. In Europe, he says a great deal of attention is given to proper repairs, which he thinks is not true in the average American city. Another reason for the superiority of European pavements, the author thinks, is that fewer pavement openings for subsurface structures are made there than here. In Europe, the authority of highway officials generally includes jurisdiction over the construction of subsurface structures.

* [illegible] Concrete Corporation, Woolworth Bldg., New York City.

Popular Books on Aeronautics

FLIGHT WITHOUT FORMULAE: Simple Discussions on the Mechanics of the Aeroplane—By Commandant Duchêne of the French Génie; author of "The Mechanics of the Aeroplane." Translated from the French by John H. Ledeboer, Editor, "Aëronautics", joint-author of "The Aëroplane." New York and London: Longmans, Green & Co. Cloth; 6x9 in.; pp. 211; 84 text figures. $2.25, net.

HARPER'S AIRCRAFT BOOK: Why Aëroplanes Fly, How to Make Models and All About Aircraft, Little and Big—By A. Hyatt Verrill, author "Harper's Book for Young Naturalists." New York and London: Harper & Brothers. Cloth; 5x8 in.; pp. xv + 245; illustrated. $1, net.

Commandant Duchene and his translator, Mr. LeDeboer, have attempted to execute a flank movement on those would-be deeper students of aeronautics who are deterred by the formidable mathematical expressions encountered as soon as they open the usual volume on the mechanics of flight and flying machines. This book gives no formulas, it is true, but it presents the same information by reverting to ordinary language—divided by, multiplied by, added to, minus, etc., in place of mathematical expressions—and by graphs, when the relations between variables become more complex.

Lift-resistance-speed relations are first presented and followed by power required for sustentation, etc. This last topic is treated at length and occupies some 30% of the book. Stability has a place of equal importance with some 40% of the pages, the matters of longitudinal, lateral and directional stability being discussed in separate sections. Many of the ideas are visualized by simple and interesting experiments easily performed by any reader.

What has been noted so far relates to manipulations in still air; for completeness a neat little discussion of air currents—steady winds and intermittent gusts—is appended as the final chapter.

The author and translator have succeeded in producing a brief treatise of appealing simplicity and pleasing literary style.

The "Aircraft Book" is made upon the usual lines of this sort of treatise and its value depends on detailed explanations of the project rather than results of approach. Conspicuous among the author's efforts are the attempts to explain flight simply enough to fit the minds of boys. Of these attempts he has expressed a most optimistic confidence in his success; however, he can be forgiven such manifest professional pride (perhaps injected by some editor) for the explanations throughout the book, though [illegible] from the engineering point of view, are good for common use.

Early in the discussion of best wing shapes, an unfortunate grouping of diagrams makes the text claim that the short broad plane is more effective than the long narrow type universally seen. A very few minor points are

presented in peculiar prospective—thus the emphasis on inherent stability of certain cambered planes, which is separated from utter instability by a narrow margin and is of no practical utility yet—as the author casually remarks.

The book seems to naturally fall into several parts. One part explains the flight and control of aëroplanes and another describes the construction of small machines. These are of two general types—propelled and gliding. The author does not recommend that boys make propelled machines of carrying capacity but he seems to think it harmless to use gliders of sufficient size to support one small person. A third division of the book describes some of the more notable types of flying machines that have been developed.

A German Textbook on Hydraulic Turbines

Reviewed by H. E. Longwell*

VORLESUNGEN ÜBER WASSERKRAFTMASCHINEN—Von Dr. Phil. Dr.-Ing. R. Camerer, Dipl.-Ing. O. Professor des Maschinenbaues an der Kgl. Techn. Hochschule, München. Leipzig and Berlin: Wilhelm Engelmann. Cloth; 7x10 in.; pp. xxvii + 577; 718 text figures and 55 tables. 25 Marks.

This volume conveys the somewhat unusual, and altogether pleasing impression that the author's first consideration has been the realization of his ideal of an engineering textbook. In every detail it exhibits the perfection of finish that marks the craftsman who cannot permit himself to slight his work in ever so small a degree.

While intended primarily as a textbook for the author's classes, it is none the less a most useful reference work for engineers already established in practice, as it presents the subject from new viewpoints, introduces new methods of calculating, and furnishes in convenient collective form a mass of information regarding successful construction of modern hydraulic turbines, and water-power plants.

The work is divided into seven parts, of which the first is a brief general introduction to the subject, treating particularly of the physical, chemical and electrical properties of water. The second part, of 160 pages, deals with hydrostatics and hydrodynamics with special reference to the needs of the turbine engineer.

Part III treats of water-power machines in general, classifying them into the various types and giving the nomenclature of each type. This section also contains an interesting historical review of the gradual development of the crude apparatus of ancient days into the modern and highly efficient hydraulic turbine. Part IV deals with the general theory of turbines, as developed from the underlying energy law, with analytical and graphical treatment of the equations derived from this law.

Having covered his subject broadly, the author proceeds to a special consideration of the two types of turbine which he regards as the only healthy survivors of the family, viz.—the complete admission, centripetal-flow turbine (Francis type), and the tangential or pure-impulse wheel (Pelton type).

Part V elaborates the general theory of the turbine with special reference to the Francis type and Part VI deals with the practical design of turbines of this class. It is interesting to note that this section is not "padded" with material that pertains strictly to pure machine design; the author confines himself to machine design as influenced by the special conditions obtaining in the particular machines under consideration. The concluding part covers the theoretical and structural design of the tangential or Pelton-type turbine.

The 718 illustrations in the text are supplemented by 55 folding plates of diagrams, halftone reproductions of photographs, and constructional drawings of actual machines, all on a conveniently large scale. These plates are grouped at the end of the book, and have page-width margins at the left, so that when they are unfolded, no part of the engraved surface is covered by the leaves of the book—an obvious convenience for the reader. There is a table of the abbreviations used in the text and a very complete table of all the symbols. In addition to the table of contents and titles of the plates, there is an alphabetical index of subjects covering nine pages.

The printing and paper are in keeping with the excellent quality of the contents. The author has that easy, graceful—almost conversational—literary style that lends a charm to even the most abstruse subject. This style is not altogether unusual in German technical works of the better class, but unfortunately translators do not seem to appreciate its desirability, and in consequence, it is rarely, if ever, reproduced.

Gas Engines for Amateurs

HARPER'S GASOLINE ENGINE BOOK: How the Engine Is Made, How to Use It at Home, in Boats and Vehicles and Elsewhere, and How to Keep It in Order—By A. Hyatt Verrill, author of "Harper's Wireless Book." New York and London. Harper & Brothers. Cloth; 5x8 in.; pp. xx + 292; illustrated. $1, net.

The constant stream of popular books on gas engines and their applications would lead one to feel that there must be something serious the matter with the previous literature available for amateur readers. If all that have been published were as good as this one, there would not be great demand for new texts. This work, it is stated, is intended particularly for boys, but in spite of such limitations it is well adapted for non-technical readers of more advanced years.

The author's introduction is a very optimistic valuation of his own work, which naturally would tend to make a critical reader prejudiced. But he has lived up to his aims for the most part in a creditable manner—whatever one may think of bold claims to "excel all others of the kind" in this or that particular.

Certain superficialities are to be expected—indeed seem almost necessary. There is no excuse, however, for careless confusion between power and torque or force, or between power and energy, as is seen in discussing the size and power of engines. Right here also is the surprising information that indicated horsepower is computed from bore, stroke and speed alone—other matters being considered constant. It need hardly be stated here that indicated horsepower is computed from mean effective pressures, experimentally determined, dimensions and speed, while the author has confused it with one of the numerous ways of nominal rating. A similar surprise awaits anyone who believes that a two-stroke-cycle engine could be appreciably more powerful than a four-stroke-cycle type of equal weight, etc. With a very few such corrections, the book will be helpful to the me-

[illegible] and automobiles, as well as to the [illegible] engines.

The [illegible] points of [illegible] types and advantages, [illegible] pressures, benefit of oiling and [illegible]. Then a little different [illegible] is made to show how the engine generates its power. Single- and multi-cylinder construction is described and special designs like [illegible], [illegible] and rotating-cylinder or "star" engines. Machines for special work, as for water and air craft and for stationary plants, are well distinguished. [illegible] present general construction features of motor cars, motorcycles, cycle cars, etc. Closing sections discuss inspection and repair and troubles to be expected. An appendix shows symptoms of troubles and remedies which should be close at hand.

Ground-Water Supplies

Reviewed by Emil Kuichling*

DAS GRUNDWASSER, SEINE ERSCHEINUNGSFORMEN, BEWEGUNGSGESETZE UND MENGENBESTIMMUNG—By Dr.-Ing. [illegible] [illegible]. Leipzig and Berlin: Wilhelm Engelmann. Paper; 8x11 in.; pp. [illegible]; 27 text figures. 3.20 Marks.

This monograph was written by a well known hydraulic engineer who has given special attention for many years to the development of ground-water supplies for German cities, and it was recently accepted by the Polytechnic School of Zurich as a thesis for the degree of Doctor of Technical Sciences. It points out the numerous difficulties that have [illegible] in placing the subject on a sound basis, and indicates how they can be overcome in large measure, so as to make subterranean hydrology an approximately exact science.

The text is divided into seven sections or chapters, which embrace a resume of the principal theories of the formation of ground-water, the interchange of surface and subsoil waters, the law of resistance to the motion of water through the ground, the efficiency of different methods of obtaining a water-supply, such as by means of vertical wells, horizontal filter galleries and artesian wells, the determination of the shape of the cone of depression of the ground-water surface by means of experiments with pumps, and lastly, the determination of the discharge of a stream of ground-water through a given [illegible] cross-section.

Wherever possible the subjects are treated mathematically, and formulas are developed for the curve of depression in terms of the pumpage, the thickness of the water-bearing stratum, and certain empirical constants, which are evaluated in a [illegible] manner. The monograph thus becomes a valuable addition to the literature of ground-water and the methods of ascertaining the probable yield for the supply of a community.

HEAT ENGINES: Steam, Gas, Steam Turbines and Their Auxiliaries—By John R. Allen, Professor of Mechanical Engineering, and Joseph A. Bursley, Junior Professor of Mechanical Engineering, University of Michigan. [illegible] New York and London: McGraw-Hill Book Co., Inc. Cloth; 6x9 in.; pp. [illegible]; [illegible] illustrations. [illegible] net.

In reviewing the first edition of this book (Engineering News, Oct. [illegible], 19[illegible]), attention was drawn to a few [illegible] that [illegible] of the book from the [illegible] volume stage. [illegible] have been [illegible] in the general [illegible] to keep up with the engineering advance in development and design of heat engines. Yet [illegible] hasty statements that were criticized in the [illegible] edition persist. There has been a general improvement and modernizing of details. The new topics cover the Stumpf "Uniflow" engine and the Humphrey direct-acting explosion pump. There are additions to the treatment of steam turbines and gas engines.

To those not familiar with the first edition, the title of the book may not convey a proper idea of its scope—which embraces elementary thermodynamics, properties of steam, [illegible], fuels, boilers, boiler auxiliaries, steam engines, engine details and testing, turbines and explosion engines.

THE AUTOCAR IMPERIAL YEAR BOOK 1914—London [illegible] Tudor St.: Iliffe & Sons, Ltd. Cardboard; 8x12 in.; pp. 12[illegible]; illustrated. 2½ shillings net.

This publication, issued by one of the principal British automobile journals, puts into permanent form, available for reference, some of the important developments of the year in British automobile engineering. The amazing development of the automobile industry in this country is matched by a similar development abroad and it is of interest to note to what a limited extent the practice of one country is reproduced in the other. The number of different makes of automobiles in England appears to be almost as great as in the United States, and the same thing is true of the enormous business in automobile parts. In the carburetor field, for example, there are 25 or 30 popular makes of carburetors in use in Great Britain which are entirely different from the equal or greater number of makes of carburetors in common use in the United States. The engineer interested in any phase of automobile development will find a great deal of valuable matter in this book. The titles of a few of the chapters will indicate its scope: The Modern Chassis, Tendencies of Design, Electric Car-Lighting Systems, Electric Engine Starters, The Progress of the Light Car, Lubricating Systems, Springing Systems, The Principal Makes of Carburetors, Royal Automobile Club's Trials of Motor Accessories and Tires, The Fuel Question, World's Records.

About the only criticism to be made of the book is that it follows the custom common to English technical and trade publications of interspersing advertising pages among the reading matter.

Automobile engineering is perhaps the youngest important branch of the engineering profession, but any civil engineer or mechanical engineer who looks upon the automobile field as a purely manufacturing field which has not yet made use of the engineer's ability to apply science to industry, will learn something if he studies such a book as the one before us.

PRACTICAL CALCULATIONS FOR ENGINEERS: For the Use of Engineering Students, Apprentices, Mechanics, Foremen, Draftsmen and Others Practically engaged in Engineering Work—By C. E. Larard, M. Inst. C. E., M. I. Mech. E., Head of the Mechanical Engineering Department at the Northampton Institute, London, and H. A. Golding, Assoc. M. I. Mech. E. Third edition, revised. London: Charles Griffin & Co., Ltd. Philadelphia: J. B. Lippincott Co. Cloth; [illegible] in.; pp. [illegible]; [illegible] illustrations. [illegible] net.

The first edition of this book appeared in 1907, and was favorably noticed in our issue of March 12th, 1908 (p. [illegible]). An enlarged and corrected edition appeared in 19[illegible] but has been out of print for some time. In the second edition the authors state that they have made

*[illegible] Mr. [illegible] [illegible] [illegible] [illegible] this [illegible].

"certain additions and a complete revision of the subject-matter;" also that they have omitted the major part of Section IV., which is to be published "as a separate volume in order to give a fuller treatment of the more purely commercial or business side of engineering." In noticing the first edition we characterized the book as designed "solely to give practice in making calculations, to help in the difficult task of converting school-taught principles into working tools."

Practical Rate Making and Valuation

PRACTICAL RATE MAKING AND APPRAISEMENT—By William D. Marks, author of the "Finances of Gas and Electric Light and Power Enterprises, 1900," and of Other Technical Papers and Works. South Hadley, Mass.: Office, Presidents House. Cloth; 5x8 in.; pp. 269. $2, postpaid.

Any posthumous volume of an engineer with a long and interesting career is bound to be of unique interest to many; in addition, the present volume has special interest as disclosing the inner workings of the mind of one who was among the oldest public-utility experts of the country.

It will be readily admitted that many of the methods used by the author had to be original, in the absence of precedents for the work which pioneer appraisers and rate-makers have done, but it must be regarded as unfortunate that he had such ties to the children of his own mind that he could not accept any and all improvements on them by some of the more recent entrants to the field. The ideas recorded here were good so far as they went, but they were after all not the only contributions in a field in which a multitude of equally earnest and sincere workers have gradually improved both theory and practice. The author's reluctance to see much good in some of these efforts is reflected in his severe and largely unmerited arraignment of the public-service commissions of various states. The explanation perhaps is found in some ungentle and ungenerous treatment by busy and thoughtless men. The ideas of a few were commended, and we suspect that the originators possessed more gentleness, deference and tact than some of their less fortunate fellows.

The first chapter contains a few very general and miscellaneous remarks on rate problems. These seem to show that the author viewed with suspicion the operation of all utility concerns in cities of over 25,000 population—on account of "growing into vendors of a commodity on a large scale" instead of "rendering service as a public servant." Here are first mentioned, the author's "proportional" or "commodity" and "time" costs which make up his total cost of utility service or product. The author's "proportional cost" includes chiefly productive labor and raw materials; his "time cost" covers interest, profit, depreciation, rent, insurance, general staff employees, etc. The author was on the right track when, years ago, he attempted in this way to adjust rates equitably between the short-time peak-load consumer and the customer who used a smaller amount for long hours. But his scheme will seem to many to be but one step toward the most equitable procedure possible, for on careful analysis "time" and "product" are not the fundamental tests. These are rather (1) the cost of readiness to serve, and (2) the cost of actual service—the former sometimes becoming indistinct, and the latter sometimes splitting naturally into a commodity and a customer charge.

Following are two long chapters summarizing reports made by the author for Spokane (gas) and Minneapolis (arc lighting). They are interesting as showing a *modus operandi*. In the gas case it might seem that the author's "time-cost" allocation, for a utility which stores a commodity, gives a rather high charge to be distributed according to demand whereas we now realize, using the readiness-to-serve test, that comparatively small investment (on storage facilities) and overhead organization charges can be properly apportioned according to peak demand, and that it is sometimes perhaps a distortion to have as much difference in unit prices as $1.40 and $1.04 for the small and the large customer or the ones of long hour and short in this particular type of utility. In the Minneapolis case, where water power is involved, these segregations do not become of such import as fixed charges and capacity reserve naturally control anyway.

In another chapter are discussed "quantity rates for electricity" in which appear again the ideas noted above. Each customer is advocated charged with a unit price which apportions "time" costs according to his probable maximum demand (total kilowatt-hours divided by connected load), and places the operating expenses according to metered quantity, disregarding diversity factors, and off-peak customers who have been won only by keeping them free from fixed charges on investment.

A considerable part of this chapter is given up to a severe arraignment of the electricity-rate system in New York City (based on steps of 10 to 5c. per kw.-hr., etc., without minimum charges) which scheme the author contends bears too heavily on the small consumers and extorts generally some $2,000,000 over a fair profit of 8%. This criticism is made in spite of the acquiescence of the Public Service Commission and is cited as a charge of incompetence and political complexion against this body.

The next chapter is called "Methods of Appraisement" and consists almost entirely of a reprint of the Act of Congress, approved Mar. 1, 1913, providing for the appraisal of railroads, there being appended only the author's claim that American roads are overcapitalized by seven billion dollars out of 12½ billion—a view not generally shared by engineers. In the following four chapters valuation discussions are continued—by suggestions for organizing an inventory-unit price attack; by use of 12½ to 15% for overhead expenses; formulation of depreciation allowances; fixing real-estate values; comparative appraisals; market value, franchise value, development expense, going values, and other intangible elements.

The remainder of the volume may be considered miscellany, more or less connected to the preceding. Under "accounts" is a brief reference to reclassifying a concern's expense reports according to the author's "time" and "commodity" segregation. Under "law of demand for electricity" is a study of rates in Massachusetts cities which shows that sales per capita seemed to depend upon an empirical hyperbolic law [sales = (640 ÷ price) − 15]. The gas sales studied exhibit greater complexity and show no such simple relation. There is a brief review of the London "sliding scale" for gas companies, by which corporation dividends are increased with price reduction, and an outline of a similar dividing scale of the author's devising by which the decrease in rates equals the increased corporation return or other factors.

Compressed-Air Pumping

Reviewed by C. R. Weidner*

PUMPING BY COMPRESSED AIR—By Edmund M. Ivens, Jun. M. Am. Soc. M. E. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 6x9 in.; pp. vi + [illegible]; 1?6 text figures. $3.

Mr. Ivens' book on Pumping by Compressed Air is, so far as the reviewer knows, the first written in the English language, which deals exclusively with that subject. An excellent German work has appeared recently, however, and the subject has also been dealt with briefly in various works on Compressed Air.

The author has compiled, in convenient and condensed form, the essential information on compressed-air pumping which has been published in technical-society journals, engineering periodicals and manufacturers' catalogs; with this he has combined matter derived from his personal practice, including tests on operating plants.

The first chapter takes up very briefly the direct-acting plunger pump operated by compressed air. The second and third chapters describe various types of displacement pumps, in which the air displaces the liquid in one or more chambers, and is then either exhausted into the atmosphere or piped back to the compressor. The results of tests on both methods and a theoretical analysis of the return-air system are given. The reviewer would criticise the allotment of space given to the over-detailed description of one of these tests, since the installation described is one rarely met with in practice. Thirty-two out of a total of 2?2 pages of text are used for this purpose, which are quoted from a readily accessible source.

The major portion of the book, chapters 4 to 8, inclusive, is devoted to the history, theory, design, tests and descriptions of the air lift. Engineers will be especially interested in this part, as the air lift offers the most advantageous field for compressed-air pumping and little of definite value has been published in English, relating to the design of this system. Although a proper design is largely a matter of experiment, the fundamental principles are clearly stated, and formulas, diagrams and tables are given, which are extremely useful. As an illustration, a set of conditions is assumed and the design worked out in detail.

Although the material in the five remaining chapters can be found in books on thermodynamics, compressed air, and hydraulics, it is, however, convenient to have it presented here. Chapter 9 relates to compression generally; Chapter 10 to the air used and to air-compressor efficiency, and practical hints on the installation and operation of the compressor are given in Chapter 11. Numerous typographical errors, or errors due to insufficient proofreading, mar Chapters 12 and 13, dealing, respectively, with the flow of air and water in pipes. The formula given in the last chapter for loss of head due to expansion or contraction of section is clearly in error.

The demand for a book of this kind has been made evident to the reviewer by the large number of requests from water-supply engineers and superintendents, chemists and manufacturers, for a bulletin on the air lift, which was published several years ago by the University of Wisconsin; and, notwithstanding the minor defects pointed out, he feels assured that Mr. Ivens's book will meet their needs. For classes in hydraulic machinery and compressed-air practice, it should be of value for reference, both to the teacher and student.

ACOUSTICS OF AUDITORIUMS—By F. R. Watson. Urbana, Ill.: Engineering Experiment Station, University of Illinois. Bulletin 73. Paper; 6x9 in.; pp. 32; illustrated. 25c.

It would be difficult to find a technical subject of direct interest to the engineering and architectural professions, on which such general ignorance exists, and which is at the same time so important, as the subject to which this pamphlet is devoted. Apparently, most engineers, and architects as well, appear to think that the acoustic properties of a public hall or other auditorium are purely a matter of luck. Knowledge of the investigations that have been made within the last 15 years to determine the laws which govern the acoustic properties of auditoriums, is not yet widely disseminated. This bulletin by Professor Watson summarizes the principal elements which determine the acoustic properties of an auditorium, and describes the various experiments and investigations which were made at the University of Illinois, especially in connection with the auditorium at the University, which was seriously defective in its acoustic properties.

It is a good illustration of the popular ignorance of acoustics, among those who should be best informed, that many of the buildings at our universities are notably bad in acoustic properties. Another illustration is the hall in the house of the American Society of Civil Engineers, in New York City, which is so bad acoustically that a large part of the proceedings of any general meeting there are lost to the audience.

One of the main elements in determining the acoustic properties of an auditorium is the extent to which its wall surfaces reflect sound. There is good reason to believe that the acoustics of the average church or auditorium are a good deal worse today than they were in the simpler structures in use twenty years or more ago, and that the reason for this is the general substitution, which has taken place during that time, of hard patent plasters as a wall covering in place of the more or less porous lime mortar formerly used. A bibliography of publications on the acoustics of auditoriums concludes the bulletin.

REPORT ON THE BUILDING AND ORNAMENTAL STONES OF CANADA—Vol. II. Maritime Provinces. By Wm. A. Parks. Ottawa: Mines Branch, Department of Mines. Paper; 7x10 in.; pp. [illegible]; illustrated.

Engineers, contractors and architects will find this a valuable reference book for building work in the Canadian Maritime Provinces. The fieldwork upon which the report is based included not only about 60 quarries, but many abandoned quarries and prospects. It is believed by the authors that every stone commercially available at the present time in that region has received due consideration. The descriptions of building stone include not only its physical and chemical characteristics, but the facilities and equipment of the various quarries for producing commercial blocks.

A STUDY OF RAPID TRANSIT IN SEVEN CITIES—Prepared under the Direction of Theodore K. Long, Member of the Chicago City Council. Bulletin No. 2, Municipal Reference Library, Chicago, Ill.: Chicago Public Library. Paper; 6x9 in.; pp. 15.

A compilation of available data and general information on the rapid-transit facilities in New York, Chicago, Philadelphia, Boston, London, Paris and Berlin, under the heads of historical development, mileage, cost of sub-

ways and elevated roads, types of elevated construction, pasesnger traffic, motive power, rates of fare, sanitary conditions and noise, general observations.

The Mechanics of Liquids

Reviewed by Winslow H. Herschel*

TEXT-BOOK OF MECHANICS—By Louis A. Martin, Jr., Professor of Mechanics, Stevens Institute of Technology. Vol. V., Hydraulics. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. Cloth; 5x8 in.; pp. xii + 223; 114 text figures. $1.50 net.

As the author points out, the science of hydraulics is based on "approximations, assumptions and the empirical results of experiments," and yet under such unfavorable circumstances he considers hydraulics as a branch of the pure science, mechanics, and remarks, "no attempt has been made to include in this text lists of the experimental constants of hydraulics." It is thus clear that the book is intended mainly to give mental training in the classroom. It is written in accordance with the plan of conquering a subject by successive attacks of increasing thoroughness, rather than by one prolonged assault. The former plan has the inherent disadvantage that the student, when he first takes up a subject in an elementary way, is in danger of acquiring wrong impressions, which can only be eradicated afterward with great difficulty. In the chapter on weirs, for example, several pages are devoted to Boussinesq's theory, and a few lines to the Francis formula, from which a student might easily infer that Boussinesq's formula is the more generally employed. Again, the outward-flow turbine is taken as the typical example, in spite of the fact that practically all modern turbines are of the inward-flow type. It is stated that the average value of the coefficient of discharge through a standard orifice is 0.60, and there is nothing to show the range of variation of this coefficient, or the comparative range of other coefficients, and yet it is just such points as this with which a practicing engineer must be acquainted. We must, therefore, regard the book, not as a handbook for hydraulic engineers, but as a text for colleges and technical schools on the mechanics of liquids, for which latter purpose it seems very well adapted.

ADDENDUM, BEING THE FIVE CHAPTERS ON MODERN ROAD CONSTRUCTION Reprinted from "Asphalts" 1914 Road Edition—By T. Hugh Boorman. New York: The William T. Comstock Co., 23 Warren St. Paper; 7x10 in., pp. 169-191; illustrated. 25c. if sold separately; incorporated in new edition of book, price of which is $2.

The review of the original edition of this book (Engineering News, Feb. 18, 1909) stated that the volume consisted chiefly of quotations from various papers and reports. The Addendum seems to be largely of the same character. It consists of a preface to a "second edition," in this country; two pages and a half on asphalt macadam roads; a considerable chapter on cold-laid asphalt roads, or reading on "Westrumite" roads, Westrumite being a patented asphalt emulsion; a chapter on bituminous road surfaces with directions for applying various asphalt treatments, and two pages and a half on the use of asphalt blocks on roads.

The Addendum does not appear to contain much new matter and gives every appearance of being hastily compiled. For instance, the American Road Builders' Association is variously referred to as the National Road Makers Convention and the American Road Makers Convention. This may seem a small point, but to one who has done library research work such confusion and lack of accuracy are inexcusable.

FARM STRUCTURES—By K. J. T. Ekblaw, Associate in Agricultural Engineering, University of Illinois. New York: The Macmillan Co. Cloth; 5x8 in.; pp. viii + 347; 159 illustrations. $1.75, net.

Now that agricultural engineering has attained a place in our state colleges and universities and has a national association of its own, it is not surprising to see a book on "Farm Structures" written by an engineering professor. The preface states that the book is intended to meet the needs of not only the teacher and student, but also those of the progressive farmer. Rightly used, it promises to serve this purpose.

The plan of this book is simple and logical. After reviewing building materials, from wood and steel to paint, glass and nails, there are a few pages on the location of farm buildings, a longer chapter on building construction and a few pages on estimating. The various kinds of farm buildings are next considered, beginning with granaries and machine sheds, continuing through various minor structures and ending with barns and the farm residence. Separate chapters are devoted to ventilation, lighting, heating, water-supply and, finally, plumbing and sewage disposal.

The author wisely refrains from going far into either the esthetic or sanitary phases of farm structures. Under sewage disposal, however, he goes farther than is necessary in setting forth underlying principles. And that is not all. He characterizes the septic tank as "the most scientific, perfect and efficient system of sewage disposal yet devised"—and describes and figures a most primitive rectangular tank. It is only fair to add that he makes it clear that the septic tank is only a preliminary means of treatment.

NEW PUBLICATIONS

[So far as possible the name of each publisher of books or pamphlets listed in these columns is given in each entry. If the book or pamphlet is for sale, and the price is known by the editor the price is stated in each entry. Where no price is given it does not necessarily follow that the book or pamphlet can be obtained without cost. Many, but not all, of the pamphlets, however, can be secured without cost, at least by inclosing postage. Persons who are in doubt as to the means to be pursued to obtain copies of the publications listed in these columns should apply for information to the stated publisher, or in case of books or papers privately printed, then to the author or other person indicated in the notice.]

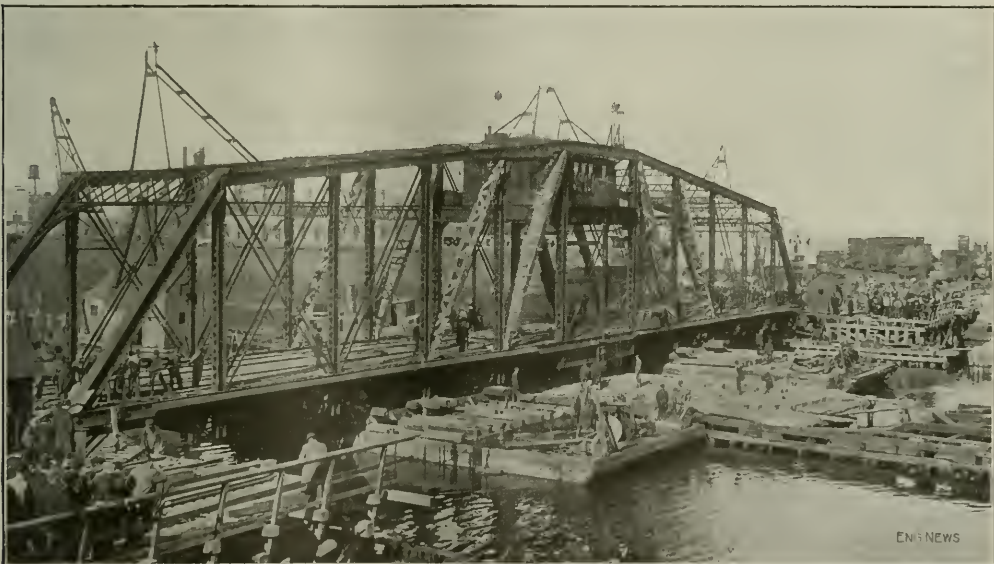
Engineering News

VOLUME 72 | NOVEMBER 26, 1914 | NUMBER 22

Shifting the Milwaukee River Drawbridge; C. & N. W. Ry.

The shifting of the 500-ton, 242-ft. double-track swing bridge carrying the main line of the Chicago & Northwestern Ry. over the Milwaukee River, at Milwaukee, Wis., was accomplished successfully on Oct. 25. The bridge was lifted off the old center pier and abutments by means of barges or scows, moved downstream about 60 ft. and placed on a temporary pier about 1 ft. above the former elevation. The time consumed was four hours, and the bridge was out of service for trains for five hours.



SHIFTING THE MILWAUKEE RIVER DRAWBRIDGE OF THE CHICAGO & NORTHWESTERN RY. AT MILWAUKEE, WIS. (OCT. 25, 1914)

(The two scows are floating the bridge down to the temporary center pier at the right of the bridge. The crowds are standing on the new temporary approaches. A group of men with one of the hauling lines is just beyond the near end post. Note the diagonals of the panels next to the center, with timber blocking to form compression members.)

The old bridge is too light for modern wheel loads and train loads, and the foundation must be remodeled for the new bridge. The line has been diverted temporarily, therefore, to leave the site clear for reconstruction, and the bridge was shifted to this temporary location. The river is about 350 ft. wide between dock lines, and the bridge crosses on a skew of about 10°, giving two 85-ft. openings with about 20 ft. of water. It had pile approaches of about 100 ft. at the north and 30 ft. at the south end. The skew and the existence of the protection pier made it necessary to arrange the scows carefully to insure clearance when moving the bridge, particularly as they were placed normal to the bridge in order to avoid undue stresses in them.

Two scows were used; one of steel 100x35 ft., and 8 ft. deep; the other of wood 112x33 ft., and 9 ft. deep. Each had four transverse and four longitudinal trusses (the latter in addition to the heavy side frames), while the steel scow had also a longitudinal and transverse watertight bulkhead. While the 500-ton load could be carried safely as a distributed load upon either one of the scows employed, each having a carrying capacity of about 100 tons per foot of depth, such scows are not designed for such heavy concentrated loads in the middle as would be caused by lifting a bridge. Therefore, all displacements and stresses in both scows were calculated carefully. This showed the necessity of reinforcing the splices in the bottom chords of trusses in the wooden scow, which was done by placing long check planks on both sides of the chord timbers at splices and bolting them up well.

To secure greater height of blocking for better distribution of loads under these conditions, the blocking was placed against the stringers instead of the floor-beams; this afforded 2 ft. greater height.

As the turntable (with wheels, center casting, rack and tread) was bolted up to lift with the bridge, and as the

scows had to be placed at a considerable distance from the center, on account of the skew of the protection pier, a reversal of stress took place in two pair of diagonal braces on each side of the center. These diagonals were eyebars and there were no counters in the panels. It became necessary, therefore, to stiffen the eyebar diagonals to enable them to take compression. This was done by wedging timbers between them and placing other timbers on the outside, all bolted together and laced with 2x8-in. plank, as shown. This bracing will remain in place for the second lift when the bridge is removed finally, after the new bridge has been completed and put in service.

The bridge is so near the mouth of the river that during gales on the lake waves as high as 2 ft. are produced at this location. It was therefore essential to make the movement when lake conditions were good, as with barges or scows filled with water to make the lift, any sudden extra load, thrown unequally on the scows, due to the surge in the river, might have serious results. Owing to a storm, a surge about 18 in. high existed at the bridge site the evening of Oct. 24, but the wind died down during the night, and conditions were favorable Sunday morning (Oct. 25). The work was decided on at 6:15 a.m., and by 8 a.m. the floating equipment had been towed to the site.

Both scows had their pumps, lines, pulleys, jacks and wedges, also as much blocking in place as the clearance allowed, the remainder having been put up at the yard and taken down by the marine crews in the way of practice and preparation. Two 6-in. centrifugal pumps had been installed on each scow at the end hatches, the pumps being fitted with rubber suction pipes so as to be adjustable for pumping water out for raising the scows or for pumping water in to sink them. Large steam siphons were placed in the end hatches to blow out any remaining water that could not be removed with the pumps, which were to be stopped when there remained only about a foot of water in the scows.

The hatches of both scows had been fitted with coamings about 18 in. high, to provide against water running over the decks and into the hatches, due to possible listing. The steel compartments in the steel scow and the partial longitudinal bulkheads placed temporarily for this purpose in the wooden scow further contributed to safety against listing, by preventing large amounts of water running rapidly from one side to the other. All pumps and siphons were fed by lines of armored steam hose, running from tugs and other floating plant, such as derrick boats, pile-drivers, etc., capable of giving ample steam, and moored both above and below the bridge before it was thrown out of service.

At 8:30, filling of the scows was commenced, to sink them enough to give ample capacity for lifting the bridge, also for the 1½-ft. extra raise on the new foundations, and to take care of a drop of about 6 in. in the river level, due to change of wind. The scows were moored on opposite sides of the river, one upstream of the bridge and the other downstream. Pumping was discontinued after 30 to 40 min., when the scows were filled to about their sinking limit, giving 18 to 20 in. of freeboard and 6½- to 7½-ft. draft. At 10 a.m. navigation was closed and the bridge was partially opened to allow the scows to be warped halfway into place under the bridge, the length of centrifugal pumps and siphons prevented the passing of equipment under the bridge when closed.

With the scows finally lined up and well moored by numerous lines, and all clearances against projections, etc., carefully attended to, some further blocking could be placed, but no jacks or wedges could be fitted until the last train had passed in each direction. This was at 11:05 a.m., after which the bridge was turned over to the contractors for removal.

A partial strain was put on the scows by means of railway jacks against the bridge, and the placing of final blocking and wedges was completed. The wooden barge in the north channel was completely blocked and wedged at noon, this being the easier scow to block, as it was on a perfectly even keel, and also had a slightly more expert crew. The steel scow used in the south channel had a slight list toward the middle of the bridge when floated into position, due to the unequal weight of pumps, which were not placed on the center line of the scow, but at the diagonal corners, on account of the hatches. A listing effect is easily produced in a steel barge when well filled with water, making it a less stable craft. In this case, however, it was merely an inconvenience in the quiet conditions of river, requiring slower and more careful wedging against the bridge stringers.

The pumps were started at 12:30 p.m., and worked full speed for some time, taking up the bridge load before the turntable showed any lifting effect, although all anchorages had been removed and steel wedges were kept well driven up under the treads to aid in the release. When the treads finally released from the masonry, it was found, as expected, that the ends of bridge had lifted more than the middle, due to the reversal of stress, and largely, perhaps, to the play in the worn pins and pin holes. The pumps were stopped about 1:15 p.m., and siphons then blew out most of the remaining water. This was completed at 1:30 p.m., the bridge then being ready to move down the river. The turntable showed a lift of 27 in. from its original position, and the ends slightly more.

The wooden scow had 4 ft. of freeboard and an average of about 10 in. of water, which was hard to remove on account of the 12-in. bottom timbers partitioning the water off into pockets. The longitudinal trusses of the scow deflected about 3 in. at the middle. The steel scow had an average of about 44 in. freeboard and only [illegible] in. deflection. It had about 5 in. of water in the bottom, this being difficult to remove on account of the watertight compartments, although temporary bypasses had been made in the steel bulkheads to equalize filling and pumping. The actual displacements of the scows conformed very closely to the advance calculations. The intention was to remove all water as nearly as practicable from both scows, preparatory to any moving of the bridge, in order to minimize the danger of listing.

No tugs or other craft were allowed to pull on the scows in shifting the bridge, these movements being made entirely by the use of numerous hand lines, which accurately controlled the movements. A competent man had been put in charge of each scow, with several marine hands at each line to follow the various directions carefully. All this was necessary, as the shifting of the bridge was not a simple downstream movement in a straight line, on account of the skew of bridge and lack of clearance for inner corners of scows along the bridge protection.

On account of the way the scows had to be placed, to take their loads, considerable maneuvering was necessary.

The old south abutment and the first span of its approach were removed to allow the bridge to be shifted south about 6 ft., after a swinging movement at the southeast corner, to clear the protection pier. The third shift was made downstream in the direction of the axis of the protection pier, until the north end of the bridge reached the center line of the new location. A slight northward movement was then necessary, the south end being allowed to continue downstream and pivot about the center of the north end, which was held stationary until the entire bridge brought up on the center line. The two ends of the bridge were then drawn up against stop timbers which centered it for alignment; wedges at the north end centered it endwise. The bridge was then held in this position ready for lowering.

The above operations took only 15 min., and the engineers then verified the location of the center of the turntable, etc., so that within 30 min. the scows were ordered filled. Pumping was started at 2 p.m.; the scows were filled in about 30 min., and wedges taken out at 3 p.m., the bridge then being in proper position on its abutments. The scows were moved out at 3:30 p.m. Track work and adjustment of ends of bridge continued, so that it was possible to let the 4 p.m. passenger train over the bridge in its new location without delay.

During the reconstruction of the foundations, the new bridge will be erected on falsework in the middle of the river and upstream from the site. This falsework will form an extension of the protection pier, and the bridge will stand parallel with the stream. It is expected that the foundation work will be completed so that early in January the new bridge will be placed in position. It will be raised by barges, moved upstream to allow of turning it crosswise of the river, and then floated down over the falsework to the new pier. It will be at the same elevation as the old bridge, with rail level 8.72 ft. above the water level or U. S. Government datum, but it will be erected on falsework 1.5 ft. higher. When this is in service, the old bridge will be removed again on barges to a distance of about 1000 ft. and there dismantled.

The old 500-ton bridge was built in 1890 and is operated by a gas engine. The new 800-ton bridge will be operated by electric motors. The piers in both cases are of stone and concrete on pile foundations, the old pier being 32 ft. square and the new pier 34 ft. diameter (octagonal). The Cleary-White Construction Co. has the contract for the substructure; the American Bridge Co. will furnish the machinery and structural material, and the Bernhisel Construction Co. will erect the superstructure, while Geo. P. Nichols & Bro. will install the power equipment. The moving of the old bridge was done by the Great Lakes Dredge & Dock Co. All these are Chicago firms. All the work was under the direction of W. C. Armstrong, Engineer of Bridges, Chicago & Northwestern Ry.

Telephone Service Rules of the Wisconsin Railroad Commission

Standards of quality of gas and electric service have been in force in Wisconsin since 1908 (see ENGINEERING NEWS, Oct. 8, 1908), but only recently has it been practical to make definite requirements of the telephone utilities, although the subject has been carefully studied all these years. The following rules were adopted Aug. 13, 1914, and are thought to be the first standards formulated—outside of the operating companies themselves. The rules are intended to fit large and small exchanges. They are on trial, and in cases of their resulting in hardship or increased cost they will be modified.

Line Construction—Rule 1. Equipment and lines shall be so constructed and maintained as to eliminate all cross-talk and noise, which unreasonable interferes with the transmission of messages for ordinary distances.

Rule 2. The number of subscribers on any one line shall not be greater than that consistent with adequate service.

(Under ordinary circumstances, rural lines should be limited to 10 or 12 subscribers, but in special cases a larger number may be justified. Service of a higher class should be rendered to subscribers who demand it and who are willing to pay the additional cost thereof.)

Rule 3. Each utility, furnishing service alone or jointly with other utilities in two or more cities, villages or other exchange points, shall provide at least one line for through traffic between such points, along which few if any subscribers' instruments are installed.

Rule 4. Each utility shall maintain in proper condition the lines, instruments and other equipment used on its system, and shall make such tests and inspections as are necessary.

Central Office—Rule 5. Each exchange shall have sufficient switchboard capacity and a sufficient operating force to handle the traffic at all times with reasonable facility. Traffic studies shall be made and recorded of such extent and frequency as to demonstrate to the commission that sufficient equipment is in use and that an adequate operating force is employed.

(Where operation is not continuous, provision should be made for handling emergency calls during such hours as the exchange is closed for regular service. Traffic studies should include the number of calls made each hour, the hour of heaviest traffic, the variation of these conditions with the day of the week or month or with seasonal conditions, and the distribution of calls among operators.)

Rule 6. Reasonable provision shall be made against the failure of lighting or power service, fires and storms, sudden increases in traffic, the illness of operators, or other emergencies which would seriously impair the service if not promptly met.

Rule 7. At exchanges serving 500 or more subscribers, 94% of the calls should be answered within 10 sec. or less. At all other regular exchanges, 90% of the calls should be answered within 10 sec. or less. At small exchanges operated in connection with other work, slower service may be adequate. Calls shall be carefully supervised and parties disconnected promptly after conversations are completed.

Rule 8. Suitable rules and instructions shall be adopted covering the phraseology and methods to be employed by operators in handling regular and special calls.

(Patrons should be required to call by number wherever practicable. It is advisable for operators to repeat the number. Telephone courtesy is extremely important in stimulating the growth of the business, and in eliminating dissatisfaction and complaints. Employees must not "listen in" on lines except when it is an operating necessity. Care must be taken to avoid diverting business from a subscriber to his competitors, or discriminating between subscribers in the attention given their calls.)

Subscribers—Rule 9. Directories in which 1500 or more subscribers are listed shall be revised at least semi-annually. All other directories shall be revised at least once each year. All directories shall be dated.

Rule 10. Directories shall contain such instructions and rules governing local and toll service and methods of payment as may be necessary to inform subscribers of their rights and obligations.

Rule 11. Reasonable efforts shall be made to eliminate interruptions and irregularities, and to correct them promptly when they occur. Records shall be kept of all complaints or irregularities in the service, showing the day and time at which the trouble is reported, the nature of the trouble, its duration and final disposition.

(Preservation of the ordinary slips filled out when the trouble is reported and the notes of the trouble man or wire chief with reference thereto will be sufficient. Subscribers should be given instructions as to how and to whom they should report difficulties. Employees should be encouraged to report all complaints, irregularities and criticisms. The coöperation of the public in promoting good service should be encouraged in the matter of tree trimming, in refraining from monopolizing party lines and in other matters not wholly within the control of the utility.)

Rule 12. The name and address of the official or employee designated to handle service matters and a copy of each new directory shall be filed with the commission. Upon request, a complete map of each telephone system shall be filed with the commission, and a similar map shall be kept at the principal office of each utility and revised from time to time as changes in the system are made.

Toll Service—No specific rules are prescribed, but the following suggestions are offered. Toll service should be properly routed so as to be most efficient and to secure justice to the telephone companies where more than one utility is involved. In general, each utility should test all toll circuits early each morning and after storms in order that trouble may be promptly eliminated. On joint lines, or when one utility uses the lines of another utility, trouble on circuits should be promptly reported to the utility responsible for the maintenance of the line. Accurate and convenient devices should be installed in order that toll charges may be just and that the service may not be unnecessarily delayed on this account. Operators should cultivate not only a distinct articulation, but low tones and pleasing voice. A record of the condition of long-distance circuits entering each exchange should be kept for the convenience of the utilities in properly maintaining their lines, and for the Commission's information.

A Freight-Handling Equipment for Fertilizer, Central of Georgia Ry., Savannah, Ga.

By F. M. Rhett*

In this country in the past, the application of machinery to cheapen and expedite miscellaneous freight handling has not been as fully developed at seaports as at other points. This is not because our seaports, as links in the chain of transportation, are new, but simply because our attention has necessarily been occupied by other phases of the problem. The insistent demands of traffic are requiring a better solution. With present-day methods of transportation, a seaport must be regarded as primarily a joint terminal for railroad and steamship. We have been occupied heretofore more particularly with the development of the railroad part of the transportation problem, and it must be conceded that we have been conspicuously successful, since our open-road service and inland terminal handling are by far the cheapest in the world.

American engineers are now attacking the seaport terminal problem in a systematic manner. There has been quite a marked tendency to develop ports in self-contained terminal units; that is, each unit including all essential terminal elements, such as railway yards, docks, warehouses, etc., and each unit also being of sufficient size to give a good working whole. The terminal of the Central of Georgia Ry. at Savannah, is such a unit.

A study of this terminal was made about two years ago with respect to three classes of commodities: Fertilizer material imported from foreign countries; miscellaneous (or so-called package) freight, handled by coastwise steamers to and from Boston, New York, Philadelphia and Baltimore; and export cotton. As a result of the study a general plan of development was prepared and certain improvements instituted. Fig. 1, a general layout of the terminal, embodies these plans so far as work which has been completed or is in progress is concerned. The improvement with respect to package-freight handling is under way; berths 1, 2 and 3 are completed and the building of slip No. 2 and adjacent facilities is in progress.

The improvements in the cotton-handling facilities are still in the initial stages, though there has been an interesting development in the application of tractor trucks for handling cotton. The improvement as to imported fertilizer material is essentially completed and tested, except as to the final ship-unloading arrangements. This article is concerned only with this phase. Although not remarkable for size, the fertilizer plant is interesting as an exemplification of seaport conditions.

Characteristics of Fertilizer

The imported fertilizer materials received at Savannah come in two forms, in bulk and in bags. The bulk material consists mostly of various grades of kainit, a [illegible]. It weighs approximately 85 lb. per cu.ft., highly impregnated with various salts of potassium. It is mined only in the vicinity of Stassfurt, Germany, and is brought down the Elbe in barges and shipped from the port of Hamburg. It is highly hydroscopic, absorbing moisture from the air in a surprisingly copious and persistent manner; when in this condition it is an excellent conductor of electricity. When handled carefully in loading it comes from the ship fairly dry, but during handling it gives off considerable quantities of dust which is almost pure salt. This, of course, settles and absorbs moisture when atmospheric conditions are favorable. Special precaution must therefore be observed in the protection of any appliance which may be used in handling it. Another physical characteristic which makes it difficult to handle is its tendency to cement together and become quite hard when allowed to stand for short periods of time. It has frequently to be blasted in the holds of ships and in storage warehouses.

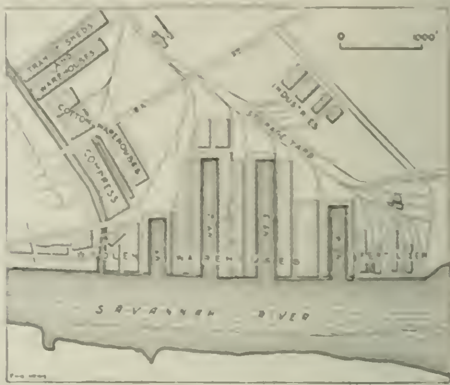


Fig. 1. General Layout of Terminal, Central of Georgia Ry. and Ocean Steamship Co. at Savannah, Ga.

The bagged material consists of various salts of potassium and kindred bases, imported from Europe, and nitrate of soda from Chile. This material is quite valuable, the nitrate, for instance, being worth about $57 per ton. The bags average in weight about 200 lb. From the very nature of the product these bags are usually badly weakened by rotting, which has proved to be a limitation in the speed of handling. The rate of acceleration incident to high hoisting speed causes failure of the bags; this limits the speed to approximately 175 ft. per min.

The material is valuable and of course must be protected from the weather. Although solid cargoes of bulk kainit are very often received, it most frequently comes in quite small lots of a few thousand tons only, which are separated in the ship and must be kept separate in the handling throughout, these lots being of different analysis or for different consignees. The usual loading consists of bulk material in the lower decks of each hatch and bags in the upper.

Ship Unloading

The contrivances for handling free flowing freight, such as coal and ore, have reached a high degree of perfection, particularly in the lake traffic. These narrow waters permit of the design of ships especially for cheap cargo handling. Seaships, on the contrary, must be designed primarily to meet rough ocean voyages. They are divided by transverse bulkheads and each ship's

*[illegible] Engineer, Central of Georgia Ry., Savannah, Ga.

space thus formed is divided by horizontal decks. The hatches are small and comparatively few in number. This renders a large percentage of the cargo area not accessible vertically from above.

The hardening of the bulk kainite in the hold requires that it be broken down and the most satisfactory method of handling it consists in the use of buckets, having a capacity of 20 cu.ft., and mounted on rollers, so as to permit being pulled into the space not directly under the hatches. This requires the use of hand labor in the hold. The only possibility of expedition consists in increased speed of hoisting. Under very favorable conditions, grab buckets may be used. For discharging the bagged material the ships' winches are used, because special machinery such as is employed in unloading solid cargoes, of cement, coffee, etc., is not warranted on account of the relatively small receipts, sorting of lots, the bad-season load factor, and other limitations, such as hoisting speed.

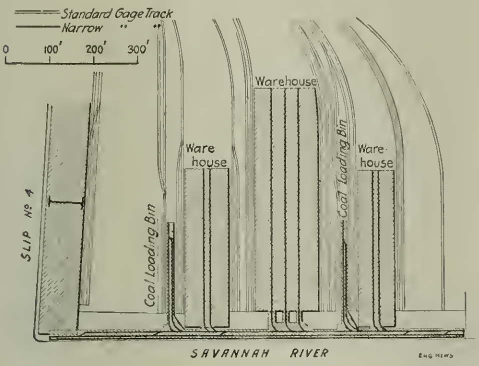

FIG. 2. DETAIL OF FERTILIZER HANDLING PLANT AT SAVANNAH

Delivery from Ship-Side

It has been pointed out that kainite is valuable, and consequently must be protected from the weather and carefully weighed. It must be handled in numerous separate consignments, since the material coming from every hatch may be different. With two ships discharging at the same time, there may be as many as six separate consignments which must be kept entirely distinct throughout all handling. This is a condition entirely different from that found in the usual bulk handling plant, such as for coal and ore.

Much the greater part is handled direct from ship-side to box-cars. The remainder must be held by the terminal company in temporary storage in warehouses.

For handling the bulk material from ship-side the most suitable plan was found to be the use of elevated electric railway with individually driven motor cars. The general scheme of operation is to convey the material to be loaded into box-cars direct from the ship-side hoppers to a system of bins for temporary storage, each bin having a capacity of 10 tons, or one carload. The material for storage is conveyed into the inclosed warehouses and there dumped from elevated trestles.

These motor cars are operated upon a 21-in. gage track system, with a 30-lb. rail, supported on 4x8-in. cross-ties, spaced 24 in. An interesting phase of the layout is the use of spring switches, thus making the switching automatic. Two tracks are provided upon the waterfront trestle and the circulation of motor cars is downstream on the outer track and up on the inner. Numerous cross-overs are provided so as to reduce the average length of the run and prevent interference, etc. The rear rail of the ship-unloading equipment is elevated so as to allow the motor cars to run under to the storage warehouses and the car-loading bins. The operation of this layout has been very satisfactory.

The motor cars are of the side-dumping type, having a load capacity of 5 tons and weighing empty 4 tons. The car body is supported through center pins on two so called maximum-traction trucks. These trucks have cast-steel side frames with rigid bolster; coil springs carry the weight to the axles; roller bearings are employed, principally for the reason that they do not require much attention. One of these cars is shown in Fig. 3. Each truck is equipped with a mine-type motor, geared to the axle; the wheel diameter is 20 in. and the gear ratio 4.77. The motors are connected in parallel, which gives a free running speed, loaded, on straight track of 10.4 miles per hour, corresponding to a tractive resistance of 21 lb. per ton and a power consumption of 68 watt-hours per ton-mile. The motor speed is 830 r.p.m. at the balancing speed of the car. Short-radius curves are, of course, used; namely, 20-, 25- and 50-ft. radius. Curve resistance is a variable quantity, depending upon speed, condition of track lubrication, etc. Measurements showed a tractive resistance of 60 lb. per ton on a curve of 25-ft. radius. A smaller radius than 20 ft. should not be used with cars of this type.

When dumping, particularly into the car-loading bins, or receiving from the ship-side hoppers, quantities of salt dust are thrown up. This penetrates the apparatus and then absorbs moisture. It is therefore absolutely necessary to use fully inclosed motors and to seal all outlets. The wiring too is very vulnerable—a good grade of rubber is satisfactory, but it is exceedingly difficult to prevent serious corrosion at the soldered joints—the use of lead cable is the best solution.

FIG. 3. MOTOR CAR USED IN HANDLING BULK KAINITE AT CENTRAL OF GEORGIA RY. TERMINAL, SAVANNAH

These cars are operated from a third-rail system. It was impossible to use trolleys on account of interfering with the overhead equipment. The third rail is a 20-lb. T-rail, supported every 10 ft. on special porcelain insulators, having large leakage distance. It was necessary

is use a low voltage on account of the formation of salt films on drain insulator resulting in severe shocks from partial grounds.

Car Loading

It was desirable to load box-cars mechanically, principally so as to attain speed and also so as to reduce the number of men required and thus simplify the control for this intermittent service in both respects. The railway tracks were necessarily at right angles to the waterfront and stub ended. The general plan of car loading is to deliver from the overhead trestle into bins spaced 45 ft. c. to c. The material is fed from these bins to portable box-car loading machines which deliver it into the ends of the cars. A partial view of a set of bins is shown in Fig. 4. In order to reduce railway switching, arrangements were necessary so as to permit shifting only once or twice per working shift. This is accomplished by providing motor-operated winches on car pullers. The empty cars are pulled in by means of these and the loaded ones pushed out.

The detail arrangements are as follows: The bins are designed to hold 40 tons of a kainite load. The bin is in the form of an inverted pyramid and was intended to fill and discharge through a [illegible] cut-off valve having an opening of 24x30 in. There were misgivings as to whether kainite could be handled in this manner owing to consolidation into a solid mass and the frequently to be blasted, both in ships and warehouses. It was found by experiment that this consolidation requires some hours and it seems to be due to the presence of moisture included in the salt. With the depth of the bin used, however, and the speed of loading of the bins, it was found that the [illegible] having an angle to horizontal of not less than 55°. On account of the limited height of the trestle, the maximum angle of chute which might be used to deliver from the discharge valve of the bin to the car-loading machine was 20°. At least 55° is required for free flow. It was therefore necessary to use mechanical feed. These chutes are built of sheet steel. They are given a reciprocating motion of 100 r.p.m. by means of a connecting rod and crank having throw adjustment of 0 to 6 in. The feeder is directly driven by back-gear type motor, which is started and stopped by a quick break oil-switch. The spring control and oil immersion of this switch permit frequent starting and stopping with little wear; the operation is very satisfactory. The rate of feed with this equipment is 3 tons per minute.

The feeder delivers the kainite to car loader as shown in Fig. 5. The essential part of the loader is a belt 22 in. wide, driven at a speed of 850 ft. per min. Nothing but

Fig. 4. Trestle over Bins for Box Car Loading of Bulk Kainite

belt was found to be able to stand the action of the [illegible] salt. The belt carriage is moved into the box-car by hand and can then be extended toward either end for a distance of approximately 10 ft.; it may also be elevated toward the roof of the car. The belt requires 10 hp. It is driven by a series wound motor, having a nominal rating of 15 hp. The [illegible] requirement was that the motor should be dust proof and extremely compact; on account of [illegible] it was necessary to use a series motor. The [illegible] depends entirely on the [illegible], the cycle of the operation being such as to require this motor, though of course it is [illegible] than necessary.

The whole machine is mounted on a four-wheel truck having 10-ft. gage and is driven on its tracks by a 10-hp. a.c. motor. This motor is used in switching empty cars and to assist in the spotting of cars opposite the bins. The belt speed is sufficient to load the car-

terial into the ends of the cars; it both conveys and projects.

The placing of box-cars is accomplished as follows: A terminal-yard crew place a string of empties on one of the two tracks leading to the box-car loading bins. Under the end of the bin trestle is placed a double-drum car-puller driven by a 75-hp. motor; the ends of a 1-in. wire cable lying parallel to the track directly in front of the bins are connected to these drums; it passes around 42-in. diameter end sheaves and slack take up is provided. This cable is driven at a speed of 120 ft. per min. It was necessary to provide a tractive effort of approximately 25,000 lb. since a string of 16 to 20 loaded cars had to be pushed out round a 12° curve. This cable is attached to a pusher or barney; a short flat-car loaded with scrap iron. The necessary number of empties, three or more, are pulled in at a time from the empty track and then pushed out on the loaded track.

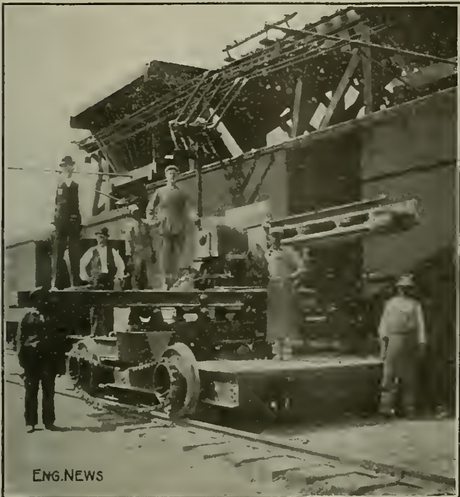

Fig. 5. Box-Car-Loading Machine at Savannah Terminal

Fig. 6. Storage-Battery Truck for Box-Car Loading

Handling Bag Material

As in the case of the bulk material, much the greater portion of the bagged must be delivered direct to the box-cars. With the stub-end arrangement of the railway tracks at right angles to the water front the haul from ship-side to cars is necessarily long. Quite a large part of this material has to be sorted for marks after being delivered from the ship, the consignments being more or less mixed in loading. In the case of solid cargoes, such as nitrate, which is very valuable, the weighing must be very carefully done and there must be considerable sampling. It is most desirable to make use of a mechanism which, at one handling, would take the material from ship-side and deliver it direct into the end of the box-car. Investigation showed the most promising machine to be the storage-battery truck.

The type of machine used is illustrated in Fig. 6. These machines are very flexible in operation; they will go practically anywhere a hand truck will go. The empty weight is 1900 lb. and the full-load capacity 4000 lb. The speed with full load and average battery voltage is 6.3 miles per hour and the free running speed light is 8.8 miles per hour. It is equipped with a 225-ampere-hour, 25-volt battery giving an output of 5.6 kw.-hr. It is really astonishing how effective this small amount of stored energy is in weight transportation. These machines will operate in regular service hauling average loads of 3000 lb. for 12 hours.

It is interesting to compare the performance of this type of vehicle with that of the narrow-gage motor cars above described. Fig. 7 shows the performance of a similar storage-battery truck having a light weight of 2600 lb. and a speed with full load of 7.5 miles per hour.

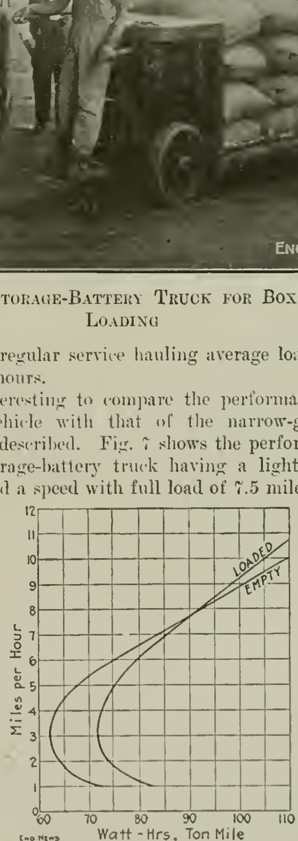

Fig. 7. Power Consumption, Loaded and Empty, of Motor Truck

(Used in freight handling on ordinary brick pavement.)

The tractive resistance of the truck is approximately 34 lb. per ton at 7.5 miles per hour and that of the motor car on 24-in. gage track 24 lb. per ton at 10.4 miles per hour; similarly the watt-hours per ton-mile of the motor cars are 68 and of the truck 88, measuring the input at motor terminals; considering the efficiency of the battery this figure becomes 117. The radically different

type of motor will also be noted, the [illegible]-type motor of the [illegible] being a [illegible]-speed machine, running at 850 r.p.m. at the full-load balancing car speed; the corresponding speed of the [illegible] motor is 2200 r.p.m.

Electrically driven machinery is used throughout the plant. Power is purchased from the local power company at 2200 volts, 60 cycles and is transformed to 440 volts for the hoists and other large motors, and is converted to 230 and 115-volt direct current for use of the railway and for charging storage-battery trucks, etc. The electrical apparatus used in the plant was furnished by the Westinghouse Electric & Manufacturing Co., other equipment by the C. W. Hunt Co.

The work thus far completed was carried out by the railway company under the direction of C. K. Lawrence as chief engineer, H. F. Sharpely being principal assistant engineer, E. M. Rhett being in charge of mechanical and electrical layout and design. The work now under way at Slip No. 2 is being handled by the Ocean Steamship Co., through J. G. Bastinger of New York.

Notes on Massachusetts Highway Work

SYNOPSIS—This article gives the results of interviews with engineers and a tour of inspection of the roads comprising the Boston district of the Massachusetts Highway Department. It gives a summary of the methods of survey and preliminary study, descriptions of the two most notable types of road surface developed in Massachusetts, [illegible] experience, and an outline of the highway department organization.

Surveys and Preliminary Studies

The first survey is made so thorough that it answers all purposes of both preliminary study and permanent location. This survey is made by a headquarters corps reporting directly to the chief engineer.

The survey line or base line is run as close to the center line of the highway as is consistent with all conditions. Stations are marked every 50 ft. with wedge-shaped wood stakes 20 in. long (square stakes used diagonally) on both sides of the traveled way. Stone monuments are afterward set on both sides of the location lines at all P. C. and P. T. stations and at intermediate distances on long tangents.

All property lines, topography, and other data to be used in design are referred to this survey line, which is shown on the preliminary plans by a full red line. The survey line is always run so as to form a closed traverse by returning over a different route, thus giving a check on both distance and direction.

PLOTTING—From this survey line the center line of the highway is offset and plotted in the office on the preliminary plans as a red dash line. Cross-sections are taken at the time of the original survey at every 50-ft. station for the whole width of the roadway. These cross-sections are plotted on a scale of 1 in. = 4 ft. on large sheets (24x36 in.) of cross-section paper in consecutive order, so that by a study of the completed plan and cross-sections, the center-line of the paved strip may be shifted to whatever part of the whole highway will give the best combination of grade, alignment, foundation, preservation of shade trees, etc. The profile of the center-line of the proposed improved road may then be worked out, and this is plotted on the same sheet with the plan (Fig. 1). It is always aimed to keep the new grade line as close as possible to the old one.

DIVISION ENGINEER'S REPORT—These plans, profiles, and cross-sections are then sent to the division engineer in whose division the improvement is projected. The division engineer studies the proposed changes in grade and alignment on the ground, and then makes a preliminary report to the chief engineer on a standard printed form. This report consists of six foolscap sheets, joined at the top, designed to be folded and filed, 8x8½ in. After noting the date of the receipt of the plans, and of the examination of the road, the division engineer fills in the following printed queries and explanations:

(1) Present road surface, character of.

(2) [illegible]

[illegible]

FIG. 1. SAMPLE ROAD IMPROVEMENT MAP AND PROFILE, MASSACHUSETTS STATE HIGHWAY COMMISSION

shall be adopted throughout the entire length of the road. When a change in section will result in a saving of stone by taking advantage of existing conditions, such a change should be recommended.)

(3) Location lines, discussion of.

(If changes can be made so as to avoid unnecessary land damages, division engineers are expected to recommend them.)

(4) Grade submitted, discussion of, with recommendations.

(5) Street railway tracks.

(Division engineers will state whether the present alignment and grade are satisfactory, and if not, what changes are necessary.)

(6) Borrow and gravel, material suitable for, location and quality of.

(Give sufficient data to permit approximate estimate of overhaul.

(7) Culverts, bridges and catchbasins.

(All structures with a span greater than 8 ft. will be classed as bridges. Division engineers will give such information as they can secure concerning drainage areas. When it appears to be necessary to obtain easements for the discharge of culverts on private land, mention should be made of the matter under this heading.)

(8) Bituminous treatment, discussion of.

(9) Foundations and drains, recommendations concerning.

(10) Guard rail, recommendations as to location of.

(11) Trees, value of, for shade.

(12) Ledge and other materials, not otherwise enumerated.

(13) Prices recommended for use in the preparation of the estimates and contracts. [Here follows a list of operations and materials with price per unit: Excavation, earth; excavation, borrow, not including overhaul; excavation, ledge; masonry; concrete, not including cement and steel; gravel; broken stone on cars; broken stone on roads; unloading stone; stone at crusher; breaking stone; teaming stone; spreading stone; watering stone; rolling stone; supervision; extra (3); total for broken stone; bituminous treatment, not including bitumen; various sizes of culvert pipe; guard rail; stone filling in place; cobblestone gutters; delivering and setting bounds; catchbasins, not including frames and grates.]

(14) Provisions for taking care of travel during construction.

(15) Remarks.

This scheme, as readily perceived, gives adequate information to the Commission and to the engineers in the main office, where specifications and contracts are drawn. Ample information regarding kind, character and method of improvement it is desirable to make is given so that final plans, profiles and specifications may be drawn that will properly fit the local conditions.

Changes in Alignment—If a new right-of-way is required, it is referred to the town in which it occurs to act, or to the abutting property owners. The state does not directly condemn land for highway purposes until after the town or property owners have made agreements relative to land damage, as the improvement of the highway is a matter of local option, and the town must not only petition for the improvement, but smooth the way over all legal difficulties before the State Highway Commission will begin an improvement.

Types of Roads

Massachusetts has no hard and fast standard of road types. It thus happens that the state is still building many miles of water-bound macadam or gravel roads, which are cheapest, with the intention and expectation of converting them into bituminous macadam or oil gravel, whenever and wherever the traffic or repair conditions warrant the additional expenditure. In other instances, a bituminous macadam, asphaltic concrete, cement concrete, brick, stone block, or any kind of surfacing, may be used on such stretches of road as experience or the judgment of the engineers shows an economic necessity.

The plain macadam sections have an ordinary depth of surfacing of 4 in. or 6 in., with a flat-sided crown of ¾ in. to 1 ft. on 15 ft. cross-sections and ½ in. to 1 ft. on 18-ft. cross-sections. The 6-in. depth cross-section has a flat base, making the section 4 in. thick at the sides, while the base of 4-in. cross-section follows the crown of the surface, making it uniformly 4 in. thick. If the road is designed to be ultimately surfaced with a bituminous material the crown is made ½ in. to 1 ft. instead of ¾ in.

The bituminous-macadam surfaces are divided into three classes: penetration, surface spraying, and layer methods. In the penetration method the lower course is bound with stone screenings or sand and the upper course is No. 2 stone with a bituminous binder. In the surface-spraying method, the surface coat is of screenings or sand and bituminous binder. For the penetration method there are ordinarily two applications of asphaltic oil, each of ⅝ gal. per sq.yd. There may also be a third application of ¼ gal. per sq.yd. for a surface finish. For the surface-treatment method there is one application of ½ gal. per sq.yd., or two applications of ¼ gal. per sq.yd. on the finished surface of the roadway.

Another form of bituminous macadam is constructed by the so called layer method, which consists of five courses, as follows: One 2½-in. (2 in. at sides) course of 2½-in. stone filled with sand and rolled dry; a second course of ¾-in. to 1¼-in. stone, practically one stone thick, watered and covered with bitumen (not rolled); a third course of the same stone, practically one stone thick, watered and covered with bitumen and lightly rolled; a fourth layer of ⅛-in. to ½-in. pea stone, watered and covered with bitumen (not rolled); a fifth course of clean, coarse, gravelly sand $\frac{1}{16}$ in. to ¾ in. in diameter. This course is thoroughly rolled. This construction requires a total of 1 gal. of bitumen per sq.yd., spread on under a pressure of not less than 70 lb. per sq.in. at a temperature of about 200° F. A similar form of construction in four layers, omitting the second course of 1¼-in. stone, requires ½ gal. of bitumen per sq.yd.

Special Types

The scheme of improvement has naturally led to individual study and experiment to utilize local materials to the best possible advantage, resulting in at least two types of road which are, or at least have been, peculiar to Massachusetts: (1) the sand and oil, mixed, or gravel and oil, mixed; (2) asphaltic concrete by the penetration method.

Gravel and Oil Mixed—The success of the sand and oil roads first constructed on Cape Cod in 1905 led to a continuation of this kind of construction. In 1910, the town of Concord laid down on the main street of Concord a pavement surface made of a mixture of gravel and hot asphaltic oil binder, the work being done under the direction of the Highway Commission's engineers, and this pavement is still in excellent condition (Figs. 2 and 3).

This type of construction is now being used on several roads where traffic does not warrant a bituminous macadam or a broken-stone asphaltic concrete, and where a good gravel is readily available and an untreated gravel would not stand. The bottom course is rolled gravel or broken field stones. The surfacing mixture is spread and rolled 2 in. thick, after the manner of sheet asphalt. After the rolling and surfacing are completed, a seal coat of asphaltic oil is distributed in two applications of ¼ gal. of oil per sq.yd. for each application. Each application of

Fig. 2. Main St., Concord, Mass., Paved with Oil-Mixed Gravel

Fig. 3. Pavement Surface

oil is covered with a thin layer of sand or screened gravel and rolled. Figs. 4 and 5 show the construction of such a road. The plant is simple and easily portable.

Asphaltic Concrete by Penetration Method—A method of spraying a layer of broken stone with hot liquid asphalt makes a pavement which looks like sheet asphalt. As this type costs less than $1 per sq.yd. for a 3-in. surface, it is the cheapest asphalt surface yet constructed. A stretch of road in the town of Weston constructed by this method is in excellent condition after two years' service under quite heavy traffic.

The asphalt used was Bermudez road asphalt, which is a true asphalt, not cutback or emulsified. It was not possible to make this type of pavement until the invention of a spraying apparatus which could handle and distribute the heavier asphalts.

Some points of the specifications for this type of road are of interest. The lower course consists of stone passing a 2½-in. ring but retained on a 1½-in. ring. The lower course is 4 in. deep when rolled. Upon this lower course is spread the upper course, consisting of stone of the same size as the lower course. This upper course is 2 to 3 in. thick after rolling, depending on traffic conditions.

Upon the upper course is uniformly distributed hot liquid asphalt at the rate of 1¾ gal. per sq.yd., and at once covered with a coating of clean pea stone, sufficient to fill the surface voids and permit a steam roller to pass over it without sticking to the asphalt. Brooms are used to spread this first coating of pea stone, and any surplus of stone is swept off the surface. A second application of asphalt is then made with a pressure distributor in such quantity as to completely coat the surface at the rate of not less than ½ gal. nor more than ½ gal. per sq.yd.

The second application must not be poured, but sprinkled or spread uniformly by means of a pressure distributor. After the second application of asphalt the surface is again covered with pea stone and again thoroughly rolled. The asphalt is applied at a temperature of approximately 300° F.

Maintenance Experience

The following notes in regard to maintenance were obtained from an interview and inspection trip with F. C. Pillsbury, who has been division engineer of the Boston district for 19 years.

For the many miles of water-bound macadam and gravel roads with which the state found itself at the be-

Fig. 4. Crushing and Screening Plant for Oil-Mixed Gravel Road

Fig. 5. Constructing First Course of Oil-Mixed Gravel Road

ginning of the automobile traffic period, the best preservative has been found to be an annual application of a light cutback asphaltic oil. Tar preparations have often given the best results, but with tar the road needs more frequent treatment and more constant attention. The light asphaltic-oiled roads invariably become muddy for a few weeks in the spring, but when promptly shaped, crowned, rolled and given a light application of new oil (about ⅓ gal. per sq.yd.), such roads remain in excellent condition for the remainder of the season.

Fig. 6. Type of Concrete Bridge Replacing Old Single-Span Truss

Roads treated with tar preparations are generally free from this mud nuisance, but on the other hand, the tar-treated road dries out quicker, cracks and disintegrates, i.e., loses its life and elasticity much sooner. Where roads could be constantly cared for and more frequently treated, tar is admitted the more satisfactory, but with a yearly or biennial treatment asphalt is preferred. Mixtures of tar and asphalt seem rather to have the bad qualities of both, so that true asphaltic oils are preferred.

These spring resurfacings and applications of oil are done as nearly simultaneously as possible throughout the whole state, both by the state's own forces and equipment and by contract with the different road-oil companies.

Besides this periodical maintenance work, a patrol system of repairing is in force. Barrels of oil are distributed at convenient places, and patrolmen are constantly making patches with a heavy asphaltic oil, which is covered with stone chips or gravel and sand.

Mr. Pillsbury recommended as probably one of the most reliable and useful tests for a bituminous road oil that for adhesiveness (described in Engineering News, Aug. 13. 1914, p. 343), by means of measuring the oil's power to prevent relative motion of two concentric cylinders. This has been found in many instances to be practically the sole test of the binding value of asphaltic oils and is considered by California chemists to be one of the most important tests.

As to maintenance and repair of pavement which is disturbed by subsurface construction, the state is amply protected by acquiring, when the road is taken over, absolute jurisdiction over all such subsurface structures. The division engineer has one assistant engineer whose sole duty it is to investigate petitions and issue permits for sewer, water-pipe, or other underground conduits, and to supervise repair work to insure that the pavement surface is fully restored.

By these methods the State of Massachusetts has maintained and kept in excellent condition many old road surfaces, representing a large original outlay, which under ordinary conditions would have rapidly disintegrated and have now been worse than useless. Such success have the Massachusetts highway engineers had in this work that they are by no means converted to the hard (brick or concrete) pavement theory. Indeed, it must be admitted that the roads in Massachusetts are hardly second to those of any state in the country, and this has been accomplished at a very modest cost, both for construction and maintenance.

Highway Organization

The Highway Department as a whole is divided into two grand divisions under the Chief Engineer, A. W. Dean. The Office Division, under A. M. Lovis, has charge of surveys and designs. The Field Division consists of four territorial divisions, each in charge of a Division Engineer.

Division 1 comprises the west and southwest section of the state, and is in charge of Division Engineer J. A. Johnston, with headquarters at Springfield. Division 2, consisting of the north central portion of the state, is in charge of Division Engineer C. H. Howes, with headquarters at Greenfield. Division 3 comprises the territory in the vicinity of Boston, on the west and north, in the eastern part of the state, and is in charge of Division Engineer F. C. Pillsbury, with headquarters at Boston. Division 4 takes in the southeasterly portion of the state, including Cape Cod and the Islands, and is in charge of Division Engineer W. R. Farrington, with headquarters at Middleboro, Mass.

Each Division Engineer has a Principal Assistant Engineer. Each contract is in charge of a Resident Engineer, who reports to the Division Engineer or his principal assistant. Minor repairs are made by a patrol system under the supervision of an assistant engineer. A slight variation exists in the different divisions in minor points in the organization, such variation being deemed advisable in order to best suit the conditions of the division.

New Dry Dock for San Francisco

Two dry docks are now maintained on the Pacific Coast for the vessels of the United States Navy, one at Mare Island, on a branch of San Francisco Bay, the other at Bremerton on the Puget Sound near Seattle. With the opening of the Panama Canal, naval operations on the Pacific assume a much more important aspect than heretofore. Neither of the above docks will be adequate for the superdreadnaughts that will frequently need overhauling on the Coast. For this reason a contract has been executed between the United States and the Union Iron Works Dry Dock Co., of San Francisco, whereby

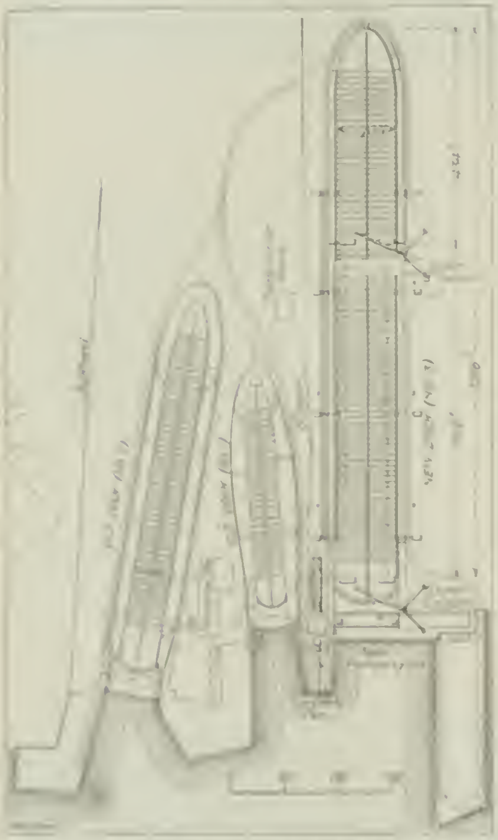

Fig. 1. Location of Two Old and One New Dry Docks at San Francisco

the latter corporation will construct a $3,000,000 dry dock in San Francisco Harbor, under the guarantee that the government will furnish at least [illegible] in business each year for ten successive years.

The new dock will be constructed at Hunter's Point, a promontory extending into the bay from the east shore of San Francisco, where two small dry docks have been in practice for a number of years. The foundation will be of solid rock, and the structure of reinforced concrete, specially designed to withstand severe earthquake shock.

Its length over all is 1006 ft., breadth between vertical walls 120 ft., breadth to top of altars 140 ft. 8 in. and depth from mean high water to top of sill 42 ft. 6 in. Its bow is elliptical and its sides parallel. They rise vertically from the floor to within 12 ft. of the top of the coping, where altars extending for almost the entire length on both sides increase the width from 120 ft. to 140 ft. 8 in.

From the center to the side drainage-gutters the concrete floor has a camber of 12 in. On it are the center keelson working platform and bilge blockways, both of wooden construction. Over the rudder pit, located near the outer end of the dock, the center keelson can be removed in sections.

The dock will be closed by an outer caisson and opened by floating and sliding this into a transverse recess in the side of the concrete structure. A similar recess and second caisson are located forward of the center, so that the dock may be used as a whole by sliding only the outer caisson into position, or the upper end alone may be used by closing the middle caisson, or both ends may be used independently at the same time by sliding closed both caissons. The outer caisson recess is drained through a tunnel 4 ft. 6 in. in diameter, which leads to the pump pit. While the caissons themselves are essentially of the sliding-box type, they can also be floated from one place to another and thus divide the structure in compartments of any desired length. They are designed so as to have ample stability without fixed ballast both when floating light or when partially flooded. This is accomplished by transverse partitions which divide the caissons themselves into three compartments, the middle one of which can be flooded or emptied without lowering the metacenter below the center of gravity.

Four inclined tunnels 10 ft. in diameter, two on each side of the dock leading to the forward and rear sections, and two open-curved stairways at the elliptical bow, provide ready access to the interior. The tunnels are closed by butterfly valves. To unwater the dock these are opened and the water allowed to drain to the pump pit, from which it is withdrawn by 54-in. vertical centrifugal pumps of the single-stage, volute type. Each pump has a capacity of 75,000 gal. per min., pumping against a head up to 42 ft. They are direct connected to 750-hp. motors, which operate at 240 r.p.m. Pump casings are of the volute form, of cast iron, in sections provided with vertical and horizontal joints, so that they may be easily removed through openings in the motor floor above. Impellers of the enclosed type will be of a bronze with a single-suction opening, and are designed to eliminate as far as possible objectionable end thrust. The bay bands are sufficiently large to permit the removal of the impellers for repairs.

Pump house and pit are to be located near the inboard end of the dry dock. The top of the pit will be [illegible] below high water or [illegible] below the top of the dock coping. Besides the four 54-in. pumps for unwatering the dock, the equipment comprises two 18-in. pumps for draining the tunnels, an 8-in. salt-water high-pressure pump, a priming pump and the operating gear for the gate valves and for the butterfly valves which close the tunnels leading to each section of the dock.

For flooding the dock a tunnel 12 ft. in diameter, controlled by a butterfly valve, leads from the bay to the pump pit. Thence the water flows into the dock through

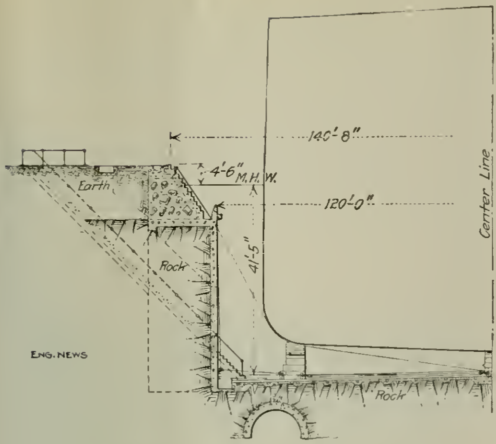

FIG. 2. HALF-SECTION THROUGH NEW SAN FRANCISCO DRY DOCK

the same tunnels by which the structure is unwatered. The operating gear which contains the flooding butterfly valve is housed separately from the main pumps in a small concrete building. The dock with tunnels has a capacity of 5,715,000 cu.ft. and with the four large pumps can be emptied in less than two hours and twenty minutes. It can be flooded in about thirty minutes.

On the port side of the dock will be a reinforced-concrete pier, with railroad tracks so arranged that cars may be landed from barges on the bay. A reinforced-concrete wharf on the starboard side approximately 450 ft. in length and 100 ft. in width at the outer end, will furnish ample wharfage facilities. Electric power will be used for the pumps and machinery as well as for the compressors that will operate pneumatic implements used in ship repair. A transformer house will therefore also be required. This will be of concrete and will be erected on the port side, opposite the inner caisson recess.

Below is a tabular description of the dock and caissons:

Length from outer meeting face to head of dock.	1096 ft.
Length from inner meeting face to head of dock	434 ft.
Length from outer meeting face to inner meeting face,	662 ft.
Width of caissons	22 ft.
Usable length of outer section of dock	640 ft.
Usable length of inner section of dock	434 ft.
Breadth between vertical walls	120 ft.
Breadth at top in way of altars	140 ft. 8 in.
Height of coping above high water	4 ft. 6 in.
Outer sill below high water	40 ft.
Depth from top of sill to top of coping	44 ft. 6 in.
Top of keelson below top of sill	1 ft. 5 in.
Height of keel blocks above top of keelson	4 ft.
Top of keel block above top of sill	2 ft. 7 in.
Top of keel block below high water,	37 ft. 5 in.
Flood camber	12 in.

	Inner caisson	Outer caisson
Length, molded	124 ft.	124 ft.
Breadth, molded	22 ft.	22 ft.
Extreme height at side	48 ft. 6 in.	46 ft. 6 in.
Light draft from third deck	8 ft. 6 in.	8 ft. 3 in.
Light displacement	620 tons	620 tons

Accessories included in the specifications are keel blocks, bilge blocks, air and salt-water piping, fresh-water

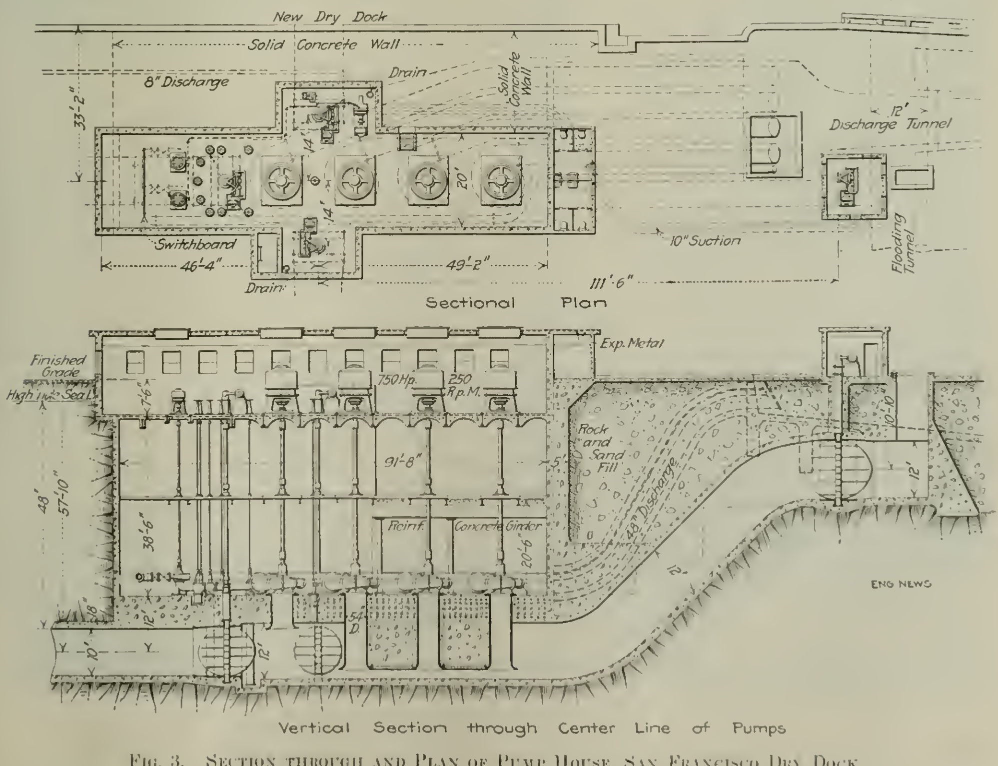

FIG. 3. SECTION THROUGH AND PLAN OF PUMP HOUSE, SAN FRANCISCO DRY DOCK

hydrants, electric windlasses, electric capstans, one 50-ton electric self-propelling traveling crane, cast-iron bitts, [illegible] piles, fenders, blocks, etc.

The dock was designed and specifications prepared by Hugo F. Frost, Assistant for the Union Iron Works Co. and Chief Engineer for the Union Iron Works Dry Dock Company.

The new San Francisco Dry Dock is among the five new dry docks which have a total length of 1000 ft. or over, all of which can dock any vessel now afloat. Two of these docks, the Gladstone at Liverpool and the Alexandra at Bombay, are completed and those at Boston and Levis are now under construction. The general dimensions of the five are as follows:

	Length ft.	Breadth ft.	Depth H.W. ft.
Boston, Mass.	[illegible]	[illegible]	[illegible]
Levis, Que.	[illegible]	[illegible]	[illegible]
San Francisco, Calif.	[illegible]	[illegible]	[illegible]
Gladstone, Liverpool	[illegible]	[illegible]	[illegible]
Bombay, India	1000	[illegible]	[illegible].3

Bulk-Cement Handling Plant, Northwest Station, Commonwealth Edison Co., Chicago

By Harold W. Robbins*

A large concreting plant handling cement in bulk is of particular interest in construction work, especially as considered in connection with the building of one of the greatest of modern power stations, the Northwest Station of the Commonwealth Edison Co., Chicago, which is planned to have ultimately a capacity of over one-third of a million horsepower. Northwest Station is projected to supply in an increasing degree the power and lighting requirements of the adjacent part of Chicago, and to supplement the power stations on the south branch of the river at Fisk St. and Quarry St., which have respectively 165,000 and 84,000 kw. capacity.

Prominent features in this construction work are: the increasing of the floor area to approximately 100,000 sq.ft. and the making provision for four new units, at least, of 30,000 kw. each, which, when they are installed, eventually will bring the total capacity of this part of the power station up to not less than 160,000 kw. Besides the 50,000 cu.yd. of excavation, there are involved 18,000 cu.yd. of concrete, 3500 tons of steelwork and 200,000 rivets. A maximum of about 400 men have been employed on the construction work, and these, with the additional men working for the subcontractors, would probably total about 700 men engaged in finishing the job in record time.

The arrangement by which the 20,000 bbl. of cement, which probably will be required for the concreting work in various sections of the station, are handled in bulk through the central concreting plant is very interesting. This type of construction equipment is not only one of the newer developments for work of this kind, but in addition to its comparatively greater capacity also permits the very efficient production of concrete.

In a general way, it is similar to the one made use of in building the foundations of the new Baldwin Locomotive Works, at East Chicago, Ind., in 1913, where over 10,000 cu.yd. of concrete were placed. The proportionately greater requirements at Northwest Station made advisable the erection of this larger concreting plant, whose general dimensions are approximately 50 ft. length, 38 ft. height over all and 15 ft. width. It comprises essentially elevated storage bins for cement, sand and crushed stone, a bucket elevator, a power scraper for unloading cement from bulk cement cars, a derrick for transferring sand and stone and a batch concrete mixer. The machinery is all electrically driven by connection with the 220-volt alternating current distributed for general use in the yards of the power station.

Description of Plant

The storage bins are large and designed to be ample for supplying material for an average day's requirements.

*[illegible] Portland Cement Co., [illegible]

Fig. 1. General View of Concrete-Mixing Plant

Cement brought in on cars in bulk, [illegible]; sand and stone brought in on [illegible]

The sand-storage bin has a volume of 1260 cu.ft. and the stone-storage bin 2300 cu.ft. The bulk-cement storage bin, located between the other two, and entirely inclosed against the weather, will hold a volume of nearly 1400 cu.ft., or 350 bbl. The unusually great weight of the

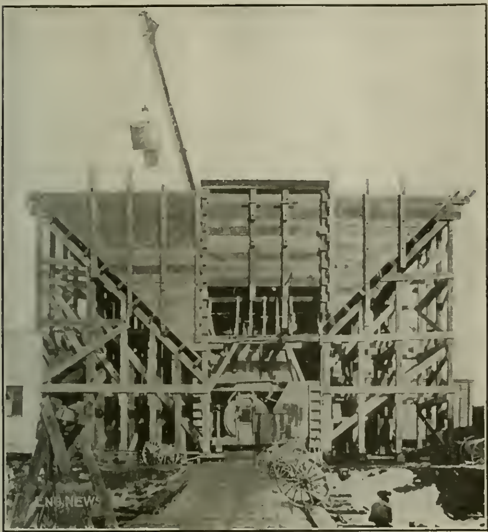

Fig. 2. Delivery Side of Concrete-Mixing Plant, Commonwealth Edison Northwest Station
(Concrete from mixer wheeled in buggies to job.)

material, supported at the elevation of 25 or 30 ft., necessitates heavy timbering for safety, and this is well taken care of by the use of 40 or more 10x10-in. supporting posts, adequately braced with diagonal timbers. As originally designed, the heavy stresses on the sides and bottoms of the storage bins were to be carried by similar 10x10-in. timbers, but it was found practicable to use steel tie-rods instead in connection with the 2x12-in. plank used for the sheathing of the bins, thus appreciably reducing the weight of the elevated sections.

In transferring bulk cement the methods usual in grain handling are employed. As the carloads of cement are received from the Buffington mills and spotted on the side track adjacent to the handling plant, the tapered chute shown in Fig. 3 is connected between the side opening of the box-car and the pit at the bottom of the elevator leg, a distance of 5 ft., and at an angle of about 45°. The chute is 9 ft. wide at the top and tapers down to about 4 ft. at the bottom. It is hinged at its lower end so that it may be swung up vertically out of the way when the cement cars are to be shifted on the side track. When resting against the side of the car, it comes just below the floor level and a canvas slip is fitted over the car edge to facilitate chuting the cement to the adjacent elevator leg.

Bulk cement is unloaded by means of a small steel scraper about 2 ft. wide, power operated, but guided inside of the car by one or two laborers. A 1-in. hemp rope leads from the scraper and around suitable blocks up to the windlass on the "shovel shaft," which is 10 ft. above the ground. Steel-spring shock absorbers connected to one of the blocks take the strain when the scraper is started with its load or in the event of its striking any irregularities on the car floor. The clutch engaging the windlass on the shovel shaft is operated by the men inside the cement car by means of a cord. The shovel shaft is gear driven from an adjacent countershaft.

The elevator (Fig. 1) is a standard type made by the Dodge Manufacturing Co., Mishawaka, Ind., and has a capacity for handling one carload of cement per hour. It is inclosed in a self-supporting steel casing, 38½ ft. in height over all, and is approximately 4x1¾ ft. in cross-section. Cement, on passing in through the grating to the bottom of the leg, is picked up by 6x6x12-in. steel buckets and discharged 35 ft. above, into the storage bin, which has a capacity of about 1½ cars. Drive is by belt from the 15-hp. motor to the countershaft, 12 ft. away. The latter is carried on wall brackets bolted to the upright timbers supporting the bins.

About 50 ft. to the north of the storage bins and with two side tracks intervening is a derrick with 80-ft. boom, by which the aggregates are transferred into the sand and stone bins, which are open to the sky. The hoisting apparatus used in raising the aggregates to the 30-ft. elevation includes an equipment of five power drums

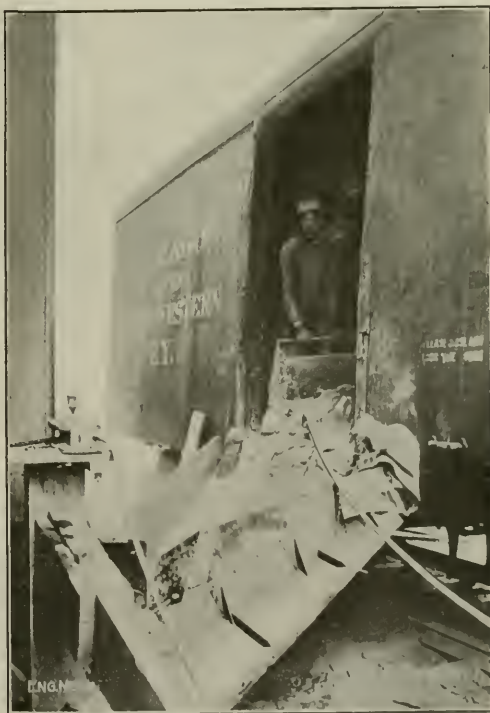

Fig. 3. Chuting Bulk Cement from Car to Elevator

operated by a 50-hp. motor. These drums control the movements of the Kieseler one-yard clamshell bucket in transferring the material from the gondolas to the storage bins or stockpiles on the ground and move the cars as they are unloaded.

In operation the bucket was observed to make a round trip from the gondola to the elevated storage bins in 40

seconds, which would permit the unloading of a 40-ton car (in [illegible]) in three-quarters of an hour. Ordinarily, eight cars per day are found to be handled readily. The crushed-stone stockpile usually has in reserve about 25 carloads and the sand stockpile contains about half of that number of loads.

Bulk cement is discharged from the storage bin through a vertical chute into the mixing hopper. In so doing it passes through a [illegible] measuring section with gates at the top and bottom. One of three [illegible]-in. holes in this section is used to gage the amount required for a given mix—that is, for the usual run or for finishing mortar. The measured cement is released through a hinged door at the bottom of the chute by the operator on the charging platform.

Sand and stone are admitted through oscillating gates to two open steel chutes sloping at an angle of 45° from the bottom of the storage bins into the 40-ft. capacity charging hopper. The opening in front of the charging hopper is covered by a canvas apron, while the cement, sand and stone are being admitted, and this is found to effectually prevent the escape of any dust.

Exit from the charging hopper is controlled by a gate operated also from the charging platform above it (Fig. 2). The water supply is arranged to be automatically sprayed into the batch as it is mixing, and to be admitted in larger quantity when the material passes from the hopper into the mixer. The $1\frac{1}{4}$-cu.yd. Marsh-Capron batch mixer is driven by a 20-hp. motor. In practice here it has been called upon to produce batches of 33 cu.ft. oftener than 40 times within an hour.

Concrete is wheeled to various parts of the work in standing buggies carrying as a rule 5 cu.ft. each. Six or seven loads are made of each batch turned out by the mixer. At times there have been the full list of 18 or 20 buggies in operation, but the production of concrete is varied steadily as there is opportunity to place it in various parts of the building.

PERSONNEL[illegible]

Besides the wheelers and [illegible] men, those actively engaged in the concreting plant are:

On charging platform:	[illegible]
[illegible]	[illegible]
[illegible]	(skill [illegible])
Trimming sand and stone [illegible]	
[illegible]	
[illegible]	

These are exclusive of the inspector employed to check the proportions of the mix and to insure uniformity.

In handling cement in bulk no labor is required on the charging platform to supply or remove sacks. In unloading a car but one or two men are needed [illegible] 250 or more barrels, using the power apparatus. In the matter of economy there is then the saving of the labor of one man in emptying sacks and of another in [illegible] handling and taking them away, while the unloading crew the [illegible] requires no extra men.

The maximum concrete placed in an eleven-hr. day has been slightly over 250 cu.yd. and the average that has been required in a 7-hour run has been 150 to 200 yd. The output is limited by the ability to use the concrete at the various points required and is a fraction of the full output of which the concreting plant is capable. In constructing the plant it was figured for a maximum daily of [illegible] batch a minute from a one-yard mixer. There is [illegible] evidence that it should be easily possible to turn out 60 batches, $1\frac{1}{4}$ yd. each, in an hour with this equipment, which would mean a possible total of over 500 cu.yd. in a day's run. The capacity of the storage bins is enough for 100 batches at least without renewal and the maximum rate of output would be easily obtainable by reason of the adequate facilities for unloading bulk cement and for obtaining sand and stone from the adjacent stockpiles or from supply cars on the siding.

The architectural design of the Northwest Station for the Commonwealth Edison Co. is by Holabird & Roche, Chicago. The steam-engineering work was laid out by Sargent & Lundy, Chicago, and the electrical work by the staff of the Commonwealth Edison Co. The Thompson-Starrett Co., of Chicago, with Fred D. Lyon in active superintendence, is in charge of the building construction and the central concreting plant was designed following the ideas of W. L. Chandler, of the Dodge Manufacturing Co., Mishawaka, Ind. The cement is shipped in carload lots from the mills of the Universal Portland Cement Co., at Buffington, Ind., a distance of 20 miles.

New Formulas for the Flow of Fluids in Pipes

By A. H. ANDERSON*

There is great uncertainty regarding the formula for the flow of fluids in pipes. The following gives a discussion of the subject.

Darcy, in 1857, found that Chezy's formula

$$f \times \frac{v^2}{2g} = \frac{d}{4} \times \frac{h}{l}$$

could be used only with a coefficient f varying with the diameter of the pipe. Engineers dealing with water have used Darcy's results, while gas manufacturers have always used Dr. Pole's formula, which is

$$Q = 1350 \sqrt{\frac{HD^5}{sL}}$$

being a solution of Chezy's formula for the given units with a value of $f =$ [illegible].

Unwin, in 1904, proposed that the value of the Chezy coefficient should be

$$f = a\left(1 + \frac{b}{d}\right)$$

where $a =$ [illegible], $b =$ [illegible], $d =$ diameter of the pipe in feet. It will be noticed that the coefficient decreases as the diameter increases.

In a paper entitled "Flow of Gas Formulas," read before the Illinois Gas Association in 1902, J. M. Spitzglass, of Chicago, has shown by extensive tests that the coefficient of friction has a minimum value for a 12-in. pipe. For smaller pipes, the coefficient increases rapidly; for larger pipes than 12 in., the coefficient also increases, but not so rapidly. This was explained by the fact that loss of head is not entirely due to skin friction between the fluid and the wall of the pipe, but also due to the relative motions in the mass of the fluid, or to the internal friction of the fluid. This was also demonstrated by Prof. Osborne Reynolds (Philosophical Transactions, 1883).

Considering skin friction alone, the head lost will diminish as the diameter increases. Considering the in-

*Assistant Professor, Mechanical Engineering, Armour Institute of Technology, Chicago, Ill.

ternal friction, the head lost increases with the cross-sectional area of the pipe. The internal friction affects the coefficient to a smaller extent than does the skin friction, but the internal friction being in proportion with the square of the diameter, the resultant coefficient reaches a point where, instead of diminishing, it slowly increases with an increase of diameter. This is borne out by the tests of Mr. Spitzglass.

The tests were made on 1-, 1½-, 2-, 3-, 24- and 36-in. pipes for low-pressure gas, and on 10-, 16- and 24-in. pipes for high-pressure gas. These experiments related only to illuminating gas and have been accepted in the gas field as authoritative. However, it is quite certain that the coefficient of friction will vary as stated, no matter what fluid is considered. This is corroborated by the fact that the fundamental hydraulic formula applies to any fluid and the coefficient of friction is taken the same for gas, water, air or steam. Therefore the writer feels justified in assuming that the coefficient of friction, depending upon the diameter, will vary the same way for all other fluids as it does for gas. From the data of the tests a new expression for the coefficient of friction was derived, as follows:

$$f = a\left(1 + \frac{b}{d} + cd\right)$$

where $a = 0.00315$; $b = 3.6$; $c = 0.03$; d = diameter of the pipe in inches.

The following table shows the deviation of Pole's and Unwin's formulas from the Spitzglass formula:

DISCHARGE IN PER CENT. OF SPITZGLASS' FORMULA

Diam. of pipe, in.	By Pole's formula	By Unwin's formula
1	150	111
1¼	135	109
1½	128	107
2	118	108
2½	112.5	104
3	108	102.5
3½	103	102
4	100	101.5
5	97	100.5
6	94.5	100.5
8	92	100.5
10	91	101
12	91	102
14	91.5	104
16	92.5	105.5
20	94.5	108
24	97.5	112
30	100.5	117.5
36	104.5	122.5
42	108.5	127.5

Formulas for Various Cases*

The expression for the quantity of discharge (derived from Chezy's formula) for any fluid has the form

$$q = 3.15\sqrt{\frac{1}{f}}\sqrt{\frac{p}{y}\cdot\frac{D^5}{l}}$$

where

q = discharge, cu.ft. per sec.;
p = friction drop, lb. per sq.ft.;
y = weight of fluid, lb. per cu.ft.;
D = diameter of pipe ft.;
l = length of pipe, ft.;
f = coefficient of friction.

Low-Pressure Air or Gas—Substitute the value of f as determined from Spitzglass' tests, and the formula becomes, for low-pressure air or gas,

$$Q = 3335\sqrt{\frac{Hd^5}{wl\left(1 + \frac{3.6}{d} + 0.03\,d\right)}}$$

where

Q = discharge, cu.ft. per hr.;
H = friction drop, in. of water;
w = density of the fluid referred to air as unity;
d = diameter of pipe, in.;
l = length of the pipe, ft.

High-Pressure Air or Gas—The equation becomes

$$Q = 64.3\sqrt{\frac{pAd^5}{wl\left(1 + \frac{3.6}{d} + 0.03\,d\right)}}$$

where

Q = discharge, cu.ft., free air or gas per min.;
p = friction drop, lb. per sq.in.;
A = average pressure in pipe line, lb. per sq.in. absolute;
d = diameter of pipe, in.;
l = length of pipe, ft.;
w = density of the fluid referred to air as unity.

Steam—For the flow of steam the equation becomes

$$W = 80\sqrt{\frac{pyd^5}{l\left(1 + \frac{3.6}{d} + 0.03\,d\right)}}$$

where

W = discharge, lb. per min.;
p = friction drop, lb. per sq.in.;
y = density of steam at mean pressure;
d = diameter of pipe, in.;
l = length of pipe, ft.

Water—For the flow of water the equation becomes

$$G = 50\sqrt{\frac{H'd^5}{l\left(1 + \frac{3.6}{d} + 0.03\,d\right)}}$$

where

G = discharge, gal. per min.;
H' = friction drop, ft. of water;
d = diameter of pipe, in.;
l = length of pipe, ft.

The writer has developed a slide-rule giving the solution of all these formulas.

*Mr. Spitzglass has developed a slide-rule giving the solution of all the formulas cited below

Track Elevation at Milwaukee, Wis., is being extended north from the Kinnickinnic River to the Milwaukee River under an order of the Wisconsin Railway Commission. The work of the Chicago & Northwestern Ry. includes 1.04 miles of the Wisconsin Division, and 0.77-mile of the Madison Division from Kinnickinnic Ave. north to the junction with the Wisconsin Division. This includes 3.6 miles of main tracks and 1.4 of side tracks, while yard tracks make the total 14.80 miles of single track. There will be three subways at Greenfield, Washington and National Ave. Two railway grade crossings will be maintained at the new elevation, and three interlocking plants installed. The station at Allis has been raised, the new basement being used as a temporary station until the tracks are raised. The underground and foundation work is finished, sand filling is in progress, and concrete deck slabs for the subways have been made and stored ready for erection in the spring. The total estimated cost is $1,225,-000, and the work is about 30% completed.

The work on the Chicago, Milwaukee & St. Paul Ry. extends from Kinnickinnic Ave. north to Fowler St. and from Clinton St. west to First Ave. The distance is about 1.4 miles, with 14 grade crossings eliminated, and a new station at Allis (National Ave.) will be required. This work will bring the track elevation into the center of the commercial district and within a few blocks of the union station. The piling is being driven, the underground work and foundations built, and the retaining walls built. The work is about 20% completed.

New York Rapid Transit Railway Extensions*

By F. Lavis†

VII--Methods of Timbering to Support the Street Surface on New York Subway Construction

The specifications for the construction of the subways in Manhattan and in most of the streets in Brooklyn require that the work be "carried on under covered roadways." This practically means that the paved surface of the street and generally one of the sidewalks has to be taken up and replaced by a timber deck, under which the excavation and construction may proceed with little or no interruption of the ordinary street traffic. Openings for shafts to give access to the excavations are permitted at intervals of 300 to 500 ft. in the upper part of the city, but are about 1000 ft. apart in the lower section.

Fig. 54. Typical Timber Decking over Subway Excavation, Showing Stringers Supporting Street Planking

In nearly all the streets in Manhattan where the subways are being or are to be built, there is a double-track street railway with underground contact system which has to be supported. In Brooklyn, the Bronx and Queens, the overhead trolley is used, which makes the problem of track support somewhat easier, though of course the poles have to be taken care of.

The usual method of procedure is first to excavate about 3 ft. of the street surface on one side of the tracks, putting in the decking and track supports in the form shown in the accompanying views. When one side of the street is decked over, the other side is taken care of in the same way.

Excavation is then carried on under this decking, the first lift being from 10 to 15 ft. in depth, practically the depth of the ordinary cellars and basements, the walls of which usually form the sides of the excavation. In very wide streets the full width is, of course, not taken out, but where the additional width beyond the building lines is not excessive, the whole width is excavated in this first lift, as this permits easy access to the buildings for the underpinning operations. Where the full width to the cellar or vault walls at the sides is taken out, no sheeting is required on this first lift, but if this is not done sheeting must necessarily be driven from the surface.

Below this first lift, the ordinary form of timbering, using rangers and braces (see Fig. 55), may be continued in much the same manner as for the excavation of any trench, though, of course, on a larger scale, or one of the many special forms hereinafter described and illustrated may be used. There are two general types, one for earth and one for rock, the former well illustrated on the left and the latter on the right in Fig. 55 and in Fig. 58 and the accompanying drawings.

The essential differences are the necessity in earth excavation of supporting the side sheeting as well as the decking and in rock the provision of a clear working space and to guard against damage by the blasting or destruction of one or more supports by the blasting oper-

*[illegible]

†[illegible] New York City.

Fig. 55. Timbering in Earth Excavation at Left and Rock Excavation at Right on Lexington Ave.

FIG. 36. STEEL GIRDERS ON STREET SURFACE CARRYING TIMBERING AND DECKING, LEXINGTON AVE., SECTION 11, ROUTE 5

ations or by slides in the very unstable New York rock.

One of the most interesting of the methods used for support in a deep rock excavation is that developed on Section 13, Lexington Ave., by Messrs. McMullen, Snare & Triest and illustrated quite clearly in the photograph, Fig. 38, and the sketch, Fig. 39.

On this section the concrete troughs which support the street-railway tracks are first supported longitudinally by the three or more 6x12-in. timbers laid flat (more than three when there are ducts to be taken care of). These, as the drawing, Fig. 39, shows, are held up by 12x12-in. cross-beams 18 ft. long, which are blocked up from the "needle beams" *F*, which are 12-in. 31½-lb. I-beams 30 ft. long spaced 10 ft. apart. It may be noted that it was not usually possible to put these needle beams directly under the blocking of the troughs of the street-railway tracks, on account of the presence of various gas and water pipes, etc., at about that level, a condition which obtains quite generally.

These needle beams have two pairs of 6x12-in. yellow-pine blocks about 5 ft. long bolted to them, one on each side and spaced so that they will come directly under the tracks, as shown on the sketch. These wooden blocks have their corners cut away so that they fit tight against the web and under the flanges of the I-beams, making at these blocks solid points of support for the longitudinal I-beam stringers underneath or for any temporary blocking or posts which may be required, and tending to prevent any overturning of the needle beam. Long X-braces and turnbuckles are also used between the needles.

At the end of the needle beam, holes are drilled so that 6x12-in. struts to the sides can be bolted to it, the 6x12's being fitted tight to the I-beam the same as the needle blocking.

The needle beams are then supported on the timber towers shown in the photograph, Fig. 38, by two pairs of 20-in. 65-lb. I-beams (*A* in Fig. 39), which are bolted together by long plates to develop full strength at the joints, making them equivalent to a continuous beam the whole length of the work. On either side of these two pairs of what might be called permanent longitudinal supports, are two pairs of the same size I-beams, bolted together the same way, the outer ones *C* 80 ft. long, and the inner ones *B* 120 ft. long, these latter being used as supports from the last timber tower over the face of the excavation to give a clear span of 50 to 60 ft. over the working space.

The inside 120-ft. pair is supported on the tower and on blocking just back of the working face, but also projects back of the tower and beyond the blocking, and these overhanging portions are wedged down tight from the decking, making it act as a cantilever (see sketch, Fig. 39). The 80-ft. pair spans from the tower to blocking ahead of the working face.

The towers are spaced 40 ft. c. to c., and as the excavation progresses, and space is cleared for a new tower, these pairs of I-beams are moved ahead for another space.

FIG. 37. STREET DECKING AND TIMBERING CARRIED ON HOLLOW STEEL PILES UNDER CHURCH ST., SECTION 1, ROUTE 5

In the timbering to support the street decking and the electric-car tracks the plan adopted on Section 9, giving continuous support to the street-car tracks by means of I-beams spliced so as to develop full strength, is worthy of note. As shown in Fig. 40, there are three pairs of these beams directly under the decking. The cross-timber on which the tracks are supported is suspended from the I-beams. The side struts or diagonals also give additional arching support so that the danger due to the displacement of any of the posts in the excavation is reduced to a minimum. Fig. 40 shows an effective method of obtaining clear support over the rock excavation for the construction of the lower-level tracks.

FIG. 38. TOWER SYSTEM OF TIMBERING IN ROCK EXCAVATION, LEXINGTON AVE., SECTION 1[illegible]

On Sections 10 and 11, after some trouble with slipping and sliding rock, an additional means of supporting the street decking was adopted. Continuous girders about 4 ft. high and 150 to 200 ft. long were erected on top of the decking near the edge of the sidewalk and the timbering was virtually suspended from them, as is shown in Fig. 41, and the photograph, Fig. 36. These girders were generally intended to be supplementary to the system of supports beneath the deck and to be necessary only in case of the displacement of these latter. As a matter of fact, however, they proved useful in spanning the space where work was actually being carried on where changes and replacements of these lower supports were frequently necessary. Their disadvantage is that they occupy space on the street surface.

Where the regular system of cross-bracing and rakers are required, as in Section 14, Lexington Ave. (McMullen & Hoff contractors), where there is earth nearly to subgrade, some very elaborate systems of timbering are necessary. The type of timber construction on this section is shown in the photograph, Fig. 35; there are seven sets of braces in a depth of about 40 ft. below the deck and the bents are about 10 ft. apart. Tension rods are put in to help hold up the bottom braces during excavation. The sheeting on this section is mostly Lackawanna steel, 14-in. arched-web, 44-lb., but some 6-in. plank (plain) is used. The steel piling mostly showed up quite well, although there were numerous boulders, and, of course, in some places where they were struck, the piling was more or less out of line toward the bottom.

On this section careful additional horizontal cross-bracing was carried diagonally from the center at each of the shafts through several bents to the sides, which added materially to the rigidity of the whole structure.

On the down-town sections, nearly all of which are in earth, more or less similar types of timbering are used. The sides are necessarily held by sheeting, generally wood, and the timbering is the usual system of rakers, braces and posts, though varied in detail by each of the several contractors.

The street decking is, of course, laid first, in some cases with a heavy wearing surface of 6-in. planks, in others 2-in. planks on closely spaced 6x6-in. timbers or 6-in. I-beams. The first cut of the excavation is then taken out to a depth of 10 or 15 ft., the street-railway tracks and pipes secured and generally one brace is carried across the whole width of the excavation, this first long brace being usually not less than 5 or 6 ft. below the surface. Great care, of course, is taken in all these methods to arrange the timbers so that they will clear the steel when the latter is erected.

The two principal variations seem to be in making either the posts or the braces continuous. On Section 2, the first operation was to sink the posts in sheeted pits to subgrade. The material was sand, and many men in New York now have become quite expert in sinking these 4x4-ft. pits in soft material by the use of horizontal sheeting (which will be described in more detail under the head of underpinning), so that the sinking of this large number of pits is not so serious an operation as might be imagined. No water, of moment, was encountered on this section above subgrade. Once the posts were down, of

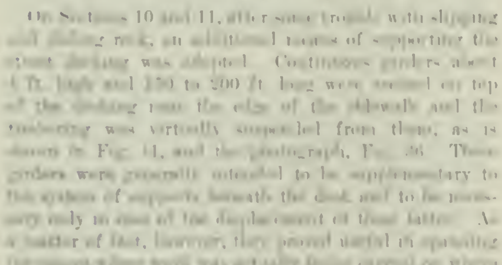

FIG. 39. [illegible] STREET DECK SUPPORTS FOR TOWER SYSTEM, ROCK EXCAVATION, LEXINGTON AVE., SECTION 1[illegible]

FIG. 40. TIMBERING FOR ROCK EXCAVATION FOR DEPRESSED SUBWAY, LEXINGTON AVE., BETWEEN [illegible] AND [illegible] STS., SECTION [illegible]

course, the deck was held in safety for any operation and the continuance of the excavation and timbering was a matter of routine.

A method used on part of Section 3 is clearly shown in Fig. 42, which needs little explanation. The building of the concrete sidewall was not followed throughout the section. The method of framing the timbers to get

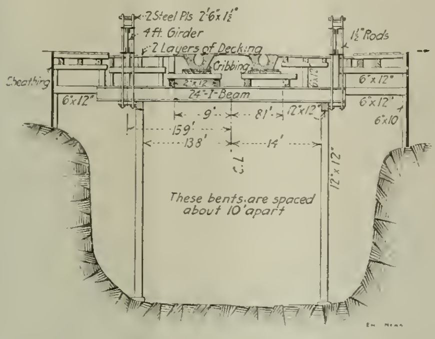

Fig. 41. Timbering Supported from Longitudinal Girders on Street Surface, Lexington Ave., Section 10.

an arching effect is, however, to be noted, as this principle was applied also on Section 1.

The features of this system as developed on Section 1, by J. C. Meem, who was the engineer in charge for the contractors, are the combined arching and bracing effect secured and the use of the continuous girder throughout the length of the excavated section, supported on posts or hollow piles.

At a convenient distance below the decking, continuous 12x12-in. cross-braces spanning the whole width of the excavation were put in, 10 ft. apart. These were usually made up of two 6x12-in. timbers bolted together in as long lengths as it was practical to use. The short 12x12-in. cap, with the ends cut as shown, was then placed under the cross-braces and supported temporarily while the next lift of 5 or 8 ft. was excavated to the level of the next cross-brace.

The hollow-steel piles were then driven, a 10x10-in. post fitted inside of them, the longitudinal girders extended, and the arch legs and posts put in position. The appearance of the lowest level is shown in Fig. 37.

The use of continuous I-beams for the support of the street decking or for tying together the timbering or supports is a feature of quite a number of the sections, differences in detail, of course, having been developed by each individual contractor, but in general the principle is that of a group or series of groups of I-beams spliced together with long plates to obtain 100% strength at the joints and running the whole length of the work under the decking and often supporting directly the street-car tracks. The advantage of this method, of course, is in its general security in case of accident to any one or even more of the supporting columns or bents and also to permit easy removal or change of supports during erection.

An interesting and unusual example of the method of timbering by rangers and braces applied to the excavation of a large area in water-bearing material is that of Sec 2-a at the intersection of Broadway and Canal St., which, on account of its difficulty, was let as a separate contract. A double-deck structure is being provided to permit the future Canal St. cross-town line to pass under the Broadway line. The excavation at this point is some 55 to 60 ft. deep and for four-track lines approximately 250 ft. long on Broadway and 150 ft. on Canal St., joined by a connecting curve in the northeast corner. The extremely heavy floor of steel girders and concrete placed in the bottom of this section to resist the water pressure, as shown in Fig. 11, will convey an idea of the conditions which were successfully overcome.

The normal water level on this section is about 15 ft. below the surface of the street, but water was actually not found in quantity until a depth of about 23 ft. was reached. This left, however, a depth of 30 ft. to be excavated in water-bearing sand and gravel. The entire area is surrounded by buildings and there is a very heavy travel to support on both streets, so that it was necessary to exercise extreme care to avoid losing ground.

The area excavated is surrounded by 6-in. tongued-and-grooved sheeting driven in three lifts, and great care was necessary in spacing the elaborate system of cross-bracing to permit the erection of the steel. There is nothing particularly novel in the layout of this latter, except its great extent over such a large area; special care, of

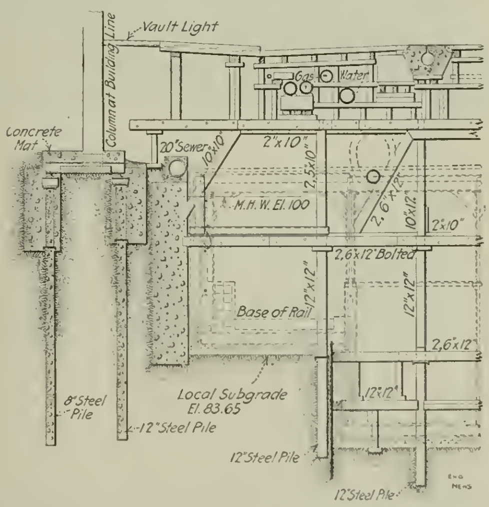

Fig. 42. Concrete Sidewalls and Arched Timber Supports with Hollow Steel Piles Used on Broadway, Section 3, Route 5

course, being necessary to keep the long line of rangers and braces in place with proper cross-bracing, and to so design the whole layout that the steel could be erected with the minimum amount of interference with the timbering.

Fortunately, the large amount of water coming into the excavation seems to be quite clear, and the most careful levels, carried out for a considerable distance in every direction from the excavation and continually checked, indicate little, if any, settlement of the adjacent ground or buildings. The total capacity of the pumps is about 20 million gallons daily, and while the whole capacity has only been infrequently required, a large proportion of it has been needed continuously.

City Switching Service with Geared Locomotives

The operating of industry tracks is one of the troublesome features of railway terminal service, due to the limited space available for sidings and connections. This necessitates the use of very sharp curves, which may be combined with steep grades in cases where the industry tracks are above or below the main-track level. The conditions are specially severe in the comparatively few cases where industry service is given to the business districts of large cities. The Kansas City Southern Ry. meets conditions of this kind at Kansas City, Mo., where its industry connections include depressed tracks leading into the basements of large establishments, and for this service it is using geared locomotives.

This industry service is an important feature both to the railways and the shippers, and the Kansas City Southern Ry. has made special endeavor to give such service to warehouses and wholesale houses, etc., within the business district. The fact that the railway can deliver cars at these establishments is an aid to it in securing traffic, while for the shipper it means the advantage of eliminating all team service to and from the freight houses and team yards. The section of the city thus served is accessible from the freight terminals only by streets having very heavy grades (about 7% maximum), which involved very heavy expense for teaming.

There is a considerable amount of industrial work on grades varying from 0.5 to 6.6 and even 7%, and on curves of 16° to 48°. The operation of switching service under such conditions is apt to be dangerous, particularly when the tracks are greasy or covered with ice or snow. In fact the ordinary engines sometimes could not be operated on the maximum grades, but with the geared locomotives there is no trouble in operating in any kind of weather. A special advantage of these engines is the absence of the noisy exhaust of ordinary engines operating on steep grades, which noise (and the accompanying discharge of cinders and sparks) would be highly objectionable in a city district.

The worst conditions are a combination of 7% grade with a 48° reverse curve having a tangent 34 ft. long. Other 7% grades have 60° curves (not compensated). The length of maximum grade is 1050 ft. Under these conditions, the ordinary switching locomotives of 34,000 lb. tractive power could handle only two cars, and similar engines having sufficient power to handle six or eight cars would be too large and too long to be operated under such track conditions. Two geared locomotives were purchased for this industrial service, but are now used also in general switching work. Their transfer work covers a distance of seven miles, and the industry work covers a territory of about ten blocks. They can push or pull trains of four to eight cars on the severe grades and can control them without the use of the brakes on the cars.

Fig. 1. 100-Ton Geared Locomotive for Switching Service on 7% Grades and 48° Curves; Kansas City Southern Ry.

From the railway company's terminal a main industry track leads up a steep grade and along the side of a street in the warehouse district and has branches laid along alleys. From the main-track lead sidings which occupy sidewalk space and run into the basement levels of the building (the siding being parallel with the main track but on a descending instead of ascending grade). From the alley lines, spurs lead into the various establishments, no cars being allowed to stand in the alleys.

In this wholesale district no objection is made to the occasional interruption of sidewalks. The railway company paves and maintains the paving along its tracks. Turnouts are placed where needed and where they are likely to be needed in future, so as to avoid having to tear up paving and tracks. These turnouts have their rails [illegible] to [illegible], thus making a substantial and permanent construction.

Owing to the way in which these engines run in and out of the "holes," they are known among the switchmen as "alley rats."

The engines are of the Shay type, having a vertical three-cylinder engine at one side of the boiler, with its crank shaft connected by intermediate shafts to a shaft on each truck. These line shafts carry bevel pinions ([illegible] teeth) engaging with bevel gears ([illegible] teeth) on the faces of the wheels. Each engine has three four-wheel trucks, one under the boiler, one under the cab and the rear bunker (for oil fuel), and the third under an independent (but permanently) coupled water tank.

The larger engine, shown in Fig. 1, weighs (with its tender) about 100 tons in working order, has 74,000 lb. tractive power and will push or pull a train of 450 tons up a combination of 5% grade and 60° curve (not compensated) at a speed of 4 mi. p. h. The smaller engine, Fig. 2, weighs about 140 tons, has 35,000 lb. tractive

power, and is designed to handle a train load of 170 tons on a 7% grade, and to pass, with its train, a 48° reverse curve with 34-ft. tangent and tracks spaced 13 ft. c. to c.

The leading dimensions of the larger engine are given in the accompanying table. The locomotive is practically a double-truck machine with power-driven tender, and the boiler and rear bunker are carried by two heavy fish-belly frames. The engine being at one side of the locomotive, the center line of the boiler is offset from that of the track. On the right side (carrying the engine) the frame is 2 ft. 9½ in. from the center of track, while on the left the distance is 5 ft. 3½ in. The engines were built by the Lima Locomotive Co., of Lima, Ohio. For information we are indebted to C. E Oakes, Mechanical Engineer of the Kansas City Southern Ry.; A. N. Reece, Office Engineer, and C. W. Streeter, Superintendent of Terminals.

Limitations of Water Filters*

By George W. Fuller†

While for some years the question of the proper loading or burden on filters has been considered in many places and attempts have been made to fix some sort of a standard which would serve the purpose, these attempts have met with very little success. The difficulties of fixing such a standard are self-evident. It is rather obvious that no exact relationship exists between the sanitary quality of the water and the number of bacteria present, no matter how the bacteria are tested, whether in the form of total bacteria or some special form, such as the colon bacillus. It is possible that some waters should have good sanitary properties and yet have a rather large number of bacteria. Other waters, again, which might be relatively free from bacteria, would show themselves to be unhealthful.

While it has been clearly recognized that some limits, definite if possible, should be placed on the proper burden for filter plants, no such limit has, until recent times, been established.

International Joint Commission Investigation

An International Joint Commission, composed in part of appointees of the United States and in part of appointees of Canada, has been investigating the question of pollution of the international boundary waters, with the idea of determining to what extent pollution must be limited in order not to endanger the health of the communities on the two sides of these boundary waters. The question practically resolves itself to this:

1. Is it possible to maintain the water in such shape that without treatment it shall be suitable for drinking water?

2. If it is not possible to maintain the water in such a condition of purity and it does need filtration before being suitable for drinking water, what is the limit of pollution allowable before the filtration plant will be overloaded and safe drinking water cannot reasonably be obtained by ordinary filtration?

The first source of information is those cities which have been receiving a supply of unfiltered water and which have sufficient data available to show how this water stands in rank on the basis of B. coli present in the water. A second source of information is the various filtered waters which are supplied to a number of communities and the records they have of coli content in this filtered water and the B. coli content in the raw water supplied to those filters. The most of our communities which do have filtered water show a satisfactory effluent and a satisfac-

*Extracts from a paper before the American Society of Municipal Improvements, Boston, Mass., October, 1914.

†Consulting Engineer, 170 Broadway, New York City.

[illegible] typhoid-fever rate, which is some measure of the wholesomeness of the water supplied. An examination of the corresponding raw water applied to the filters gives some indication of where a reasonable standard limit should be placed. A third source of information is the consideration of a standard of efficiency of bacterial removal and the assumption of a reasonable number of B. coli in water supplied for drinking purposes and a corresponding calculation of what would be a proper natural limit of B. coli in the water supplied to the filters under these conditions.

The best that can be done with the data at hand is to consider and properly weigh them, and on the basis of a rather general judgment come to some conclusion on what is a proper limit of B. coli in water to be applied to the filters. Such a conclusion should be considered an average rather than a rigid limit for any particular case. This standard specifies that water applied to filters should show by the presumptive test not more than 500 B. coli per 100 c.c. of water as a yearly average, meaning by this that B. coli should not be found more than 50% of the time in 0.10-c.c. samples. For averages for shorter selected times, monthly, weekly, or daily, the allowable B. coli content may be considerably higher. It is believed that for this purpose the averages based on a year's readings are more useful than averages for a shorter time with a corresponding different standard of allowable B. coli.

The bacterial efficiency of a filter is not an invariable quantity. Roughly speaking, 98 to 99% may be placed as a fair average under ordinary conditions. Percentages, however, are not always a good gage of efficiency, as a water with an initial bacterial content that is high will show a proportionately higher efficiency in a filter than a water with a low bacterial content, and yet the resultant filtered water may be much less satisfactory to the consumer from a health standpoint than would be the case with the other filter with a lower bacterial efficiency. In addition, sterilization is usually applied in modern filter plants as a reserve factor of safety, and should be available to be applied in all plants, and with the use of effective sterilization added to properly filtered water an effluent can be obtained which is almost, if not entirely, sterile for ordinary uses.

With these conditions in mind, it seems reasonably safe to say that a water having in its raw form a B. coli content not exceeding 500 per each 100 c.c., based on yearly averages, will show in the water supplied to the consumer something not more than one to two B. coli per 100 c.c. Such water is believed to be a safe water, when properly sterilized, for drinking purposes and for all other domestic uses.

A Small Reinforced-Concrete Dam with a Large Upstream Apron of Concrete Paving

(Contributed)

A private reservoir recently created in northeastern New York has become locally famous because of the large amount of concrete placed for such a small project. Enquiries and comments show that a certain knowledge of the peculiarities of the construction is spreading so that all [illegible] should be recorded. The project will be recognized at once by those who have previous knowledge of the work; to others it will be the details and not the persons involved that are of interest, so that names have not here been given. The reservoir in question is for purely private service and exact figures on the design and construction have been refused; however, such as are given below are believed to be closely approximate.

In 1909, work was started on a small dam to impound the waters of a little stream, flowing toward Lake Champlain, so that the seasonal flow might be equalized for the better development of electric power on a large farm where many operations were carried on by motor-driven machinery. Surveys were made by a firm of civil engineers in a near-by city and designs were worked out by them in connection with a well known firm of consulting engineers. Finally the latter were asked to supervise the construction of a hollow reinforced-concrete dam in accordance with the plans submitted.

These plans called for a deck, supported by triangular

Fig. 1. Downstream Side of Dam, Showing Gate House and Unassembled Steel Conduit

buttresses approximately 1500 ft. in length, with the crest 45 ft. above the stream bed. The initial contract was placed with a local contractor and the work of clearing the reservoir site of undesirable material was immediately started. The cleared area totaled 160 acres, the greater part of which was solid rock floor.

Little trouble was experienced during construction, until a portion of the structure, located east of the stream, was reached. But there, interesting conditions were met with in the excavation of the foundation trench. While along that portion of the dam west of the stream and extending to the east bank the rock appeared and formed the natural surface, immediately upon leaving the east bank the drift of the rock away from the surface was so very rapid that it was found necessary to dig a trench 40 ft. deep, more or less, and at some points nearly as wide, in order to obtain a satisfactory foundation for the footings.

No little difficulty was experienced in making this excavation, owing to the unusual number of large boulders distributed at various depths throughout the entire length of this portion of the trench. These varied from 3 to 8 ft. in diameter and were surrounded by coarse gravel, much of which was so compact that its removal

was made possible only by the use of dynamite. The hazardous nature of the excavation and the trouble experienced in retaining sheeting in place after driving made it almost impossible to keep laborers on the work for any length of time.

A 100-ft. spillway, of the ogee section, is located at the western end of the main dam, at an elevation 2 ft. lower than the crest. It is equipped with adjustable flashboards, constructed from 3-in. plank, securely cleated together and attached with strap hinges to a 6x8-in. sill that is firmly anchored to the spillway top. The boards are braced against the downstream toe of the dam.

From the western end of the spillway, a cutoff wall of gravity section, having a batter of 6 in. to the foot, upstream, was extended for 325 ft., more or less. Likewise from the eastern end of the main dam a wall of similar design, but of greater dimensions, was extended several hundred feet into the slope.

After the structure was completed according to plans, an attempt was made to fill the reservoir, with decidedly unsatisfactory results. Owing to the porous character of the soil in the east slope, the water upon raising its level began a steady seepage, which increased rapidly with the increased head, to the end that one farmer, living some distance outside the eastern slope, was seriously inconvenienced by the flow. This result was not wholly unexpected, as before construction had started the consulting engineers must have pointed out the very questionable nature of the site on account of the character of the east bank. Indeed the whole countryside is known to have been subjected to severe glacial action. The owner, however, very greatly desired the reservoir at this point and evidently ordered the work to proceed in spite of the undesirable conditions.

Fig. 2. Spillway with Adjustable Flashboards

At this time any immediate attempt at storage was abandoned, and it was decided by the engineers to lay a sheet of concrete, 6 in. in depth, more or less, over that portion of the south slope—some 50 acres or more in extent—through which the leakage occurred. As an additional preventive, a cutoff wall was extended in a northerly direction, approximately, paralleling the stream for a distance of 2500 ft., more or less, this wall forming an impervious joint with the floor sheet and going down to rock. It reached a depth of 35 to 40 ft. for a considerable distance.

The heavy seepage was stopped, but in the summer of 1914 there was still considerable water leaking out. There may be a seam in the rock or places where the cutoff wall does not connect with rock. One reason, undoubtedly, lies in the large and numerous cracks in the concrete floor due to temperature changes, settlement, shrinkage, etc. There are also cracks at the junction of floor and cutoff wall. Very recently, the reservoir has been drained, the floor washed down and the cracks repaired; probably, the necessity for such repairs was

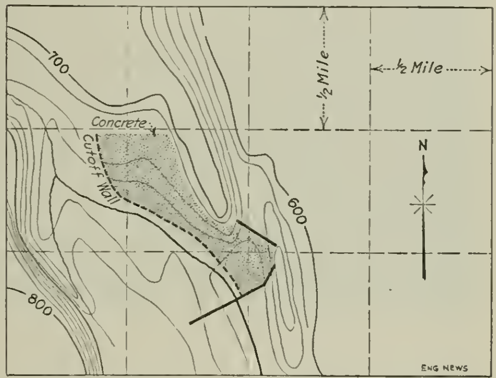

Fig. 3. Sketch Showing Approximate Location of Dam and Concrete Apron

fully known before the concrete was laid and no doubt they were judged to be preferable to greater attention at first to expansion joints, better foundation, etc.

The work on the penstock and power house of this project is progressing rapidly and there is little doubt as to the final technical success of the undertaking. It is obvious, however, that the expense incurred in the whole work was far beyond what would be possible for any commercial enterprise in a hydraulic development of such size and nature. The first estimates of the cost of the project were in the vicinity of $200,000. It is reported locally that the whole work, when completed, will approach $1,000,000.

The Largest Chain-Drive Transmission in the World is said to be that of the Ox-Bow hydro-electric plant on the Snake River at Copperfield, Ore. The installation consists of one 3600-kw., three-phase, 60-cycle generator, running at 225 r.p.m., operated by two water-wheel units. Each of these units consists of two pairs of water wheels of the horizontal type, with 48-in. center discharge, set in open flume, and operating at 21 ft. head and 147 r.p.m. The water is supplied through a tunnel cutting off a bend in the river. Each water-wheel unit is connected to the generator by four Morse chains 21 in. wide, with sprockets of 2-in. pitch on the line shafting, and with shaft centers 10 ft. apart. The generator shaft is in the center and 5 ft. above the level of the water-wheel shafts. This chain drive is said to be three times greater in size than any previously built, the largest one previous to this being at Indianapolis, Ind., and driving a 1200-hp. generator. The Ox-Bow plant was designed originally to operate under a 45-ft. head obtained by a natural fall of 21 ft. by the tunnel through the bend in Snake River, and the building of a diversion dam across the river below the tunnel. Both the water-power and electrical machinery were purchased for this head, but due to financial troubles the company was unable to build the dam and for four years the property lay idle. The plant was put in operation on Sept. 30. It was designed by the W. H. Rosecrans Engineering Co., of Chicago.

Field and Office

Quarrying with Air Hand Drills on Scaffolds, Slings and Ladders

By [illegible]*

Certain new methods of ledge and cliff excavation have been successfully developed since the advent of the self-rotating hammer hand drill which would have been impractical with all previous types of drills. Formerly, the familiar bench method was used, the rock being removed in strips whose depth and width depended upon the size of mounted drills employed. Frequently deep holes were

Fig. 1. Section of Bench Drilling at Campbell & Dence Quarry, Stone Plains, Tenn.

cut from the top of the cliff by [illegible] drills and drill [illegible].

In the new method a support for the [illegible] to [illegible] over the edge of the cliff. There being no drill mounting to adjust, the time consumed in setting up and [illegible] is practically eliminated. This alone consumes a large part of the time of operating with all types of mounted drills and explains the great economy of hand drilling. Yet the methods here described would have been impractical with ordinary hand drills due to the difficulty of holding them by hand in [illegible] positions.

Figs. 1 and 2 show the scheme employed at the Campbell & Dence Co. quarry, Stone Plains, Tenn. The rock is a hard blue limestone. Formerly, mounted piston drills ([illegible]-in. cylinders) were employed to remove the rock in benches. These were capable of drilling holes up to about [illegible] ft. in vertical direction and a maximum depth of about 18 ft.

The present procedure is as follows: A row of vertical holes 18 ft. deep and spaced 6 ft. apart is put in parallel with the face of the cliff by the tripod drills. Two lengths of gas pipe are inserted in the proper holes and ropes are fastened to them so that a scaffold can be lowered over the face of the cliff. The scaffold, shown in Fig. 2, is 11 ft. long and about 4 ft. wide. It is fitted with winding drums so that the drillers can raise or lower it after it has been slung over the cliff. The hand-drill holes are spaced 6 ft. apart, vertically and horizontally, and are 10 ft. deep. At this depth, the steels cut to about 1⅜-in. bottom diameter. The holes are inclined downward at an angle of about 20° from the horizontal. Under present conditions, one man with a hand drill sinks about 80 to 100 ft. of hole per 10-hr. shift.

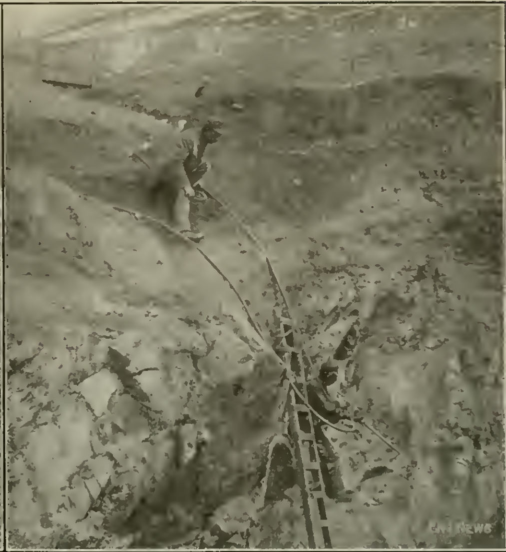
After the 10-ft. holes have been drilled from the top of the cliff to near the bottom, tripod drills are again put into use for drilling a line of horizontal holes on the very bottom of the cliff, these holes being 14 ft. in depth and looking down slightly from the horizontal. The holes in the side of the cliff are loaded each with 12 sticks of 60% dynamite and those at the bottom with 18 sticks. All of the holes are shot simultaneously (by battery). The cost of powder per cubic yard of broken stone is about 3½c. with this system whereas last year, when only tripod drills were used, the cost was 5½c.

Several big blasts have already been made. In the first shot that was set off an insufficient quantity of powder

Fig. 2. Scaffold Near Base of Cliff, Campbell & Dence Quarry

was used, which resulted in large ... of some of the stone. Later, [illegible] lb. was used (as stated above), and the cost quoted is based on this. It is believed that the amount can be reduced slightly, and it is also contemplated using a slightly longer scaffold so that two or three drills can be used at once, which would result in a further low-

*[illegible]



FIGS. 3 AND 4. HAND DRILLS IN USE AT BULLWHACKER MINE, BUTTE, MONT.

ering of operating cost. With the 350-lb. charge of powder, the rock is so well broken up that practically all of it can be handled by the steam shovel and crushers, requiring practically no block-holing.

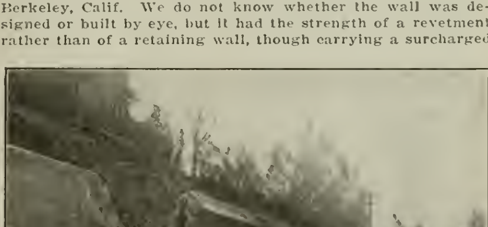
The ease with which the automatically rotated hand hammer drill is handled in inaccessible quarters is further illustrated by Fig. 3, showing work at the Bullwhacker Copper Co. mines in Butte, Mont. The difficult nature of the "glory-hole" mining here may be realized when it is considered that it is 75 ft. from the operator's position to the bottom of the cut, where the broken ore is mucked into cars and hoisted on an incline to the surface. The material is relatively low grade, averaging 4% copper, the vein running about 125 ft. wide at this point.

Frequently the operator works from a boatswain's chair slung over the side of the cliff. Fig. 4 shows a scheme for drilling in a particularly difficult spot where a suspended ladder had to be resorted to. The operator is braced against the ladder and has only sufficient room for one foot on the rock. In spite of the exceptional difficulties at the Bullwhacker mine, the remarkable speed of 90 ft. of hole in two hours has been made, each hole bottoming at 6 ft. The rock, however, was not hard, it being an oxidized granite. Three-foot starting steels were used, followed by 6-ft. drills, the holes being for $1\frac{1}{4}$-in. powder sticks. In a single month, one drill broke enough ore to fill 64 cars of about 50,000 lb. each.

In the two instances cited, it would be quite impossible to employ heavy piston drills. Ordinary plug drills would also be extremely difficult to operate because of the difficulty of rotating them by hand in such cramped quarters. With the self-rotating hand type, however, the operator has merely to apply the tool to the spot to be drilled and open the throttle. A simple steel holder attached to the front head of the hand drill has been found of material aid in withdrawing the steel from the hole. Moreover, it enables the drill runner to lower and raise the steel in the hole, churning up the cuttings and preventing sticking or binding. The latter troubles are still further provided against and the speed of cutting has been increased by a hole-cleaning device with which the operator can send at will a jet of air through the hollow steel to the bottom of the hole.

The writer desires to acknowledge the assistance of L. F. Thompson, of Knoxville, who furnished the data concerning the Campbell & Deane quarry, and of C. M. Hansen, of Butte, who supplied the information on the work at the Bullwhacker mine.

An Overturned Retaining Wall—That structures do not always do what is expected of them is illustrated by the adjoining picture of a 4-ft. retaining wall on Panorama Way, Berkeley, Calif. We do not know whether the wall was designed or built by eye, but it had the strength of a revetment rather than of a retaining wall, though carrying a surcharged



RETAINING-WALL OVERTURNED BY SLIP OF CLAY BACKING, BERKELEY, CALIF.

clay bank. It was only 10 in. thick, without batter front or back, reinforced in the main horizontally (i.e., not at all as regards retaining-wall action), and provided with only occasional counterforts. Worst of all, the soil here is very liable to slip during the winter rains. As a result, the wall recently tipped over as the picture shows. It has been replaced with a somewhat lower wall, of wedge section and counterforted.

Conveying Concreting Materials by Belts, at the Hell Gate Bridge

Belt conveyors have been installed at Randall's and Ward's Islands, New York City, for handling concrete material from boats to storage piles, in the construction of the Hell Gate bridge, spanning the East River. The belt at Ward's Island is [illegible] ft. long by [illegible]-in. wide and inclined at [illegible]°. At Randall's Island a 20-in. belt is used.

The sand and stone or gravel are lifted by the belt to storage piles, where they are dropped by a tripper. From the piles they are later rehandled into cars for distributing to different parts of the work. Coal for the dinkey engines is conveyed by the belt in the same manner. The bags of cement are discharged from the belt on a table in a storage house, where they are piled.

The number of men employed on this work at Ward's Island is as follows: A derrick hoist operator on the scow, a man to direct the sling, three to make up the

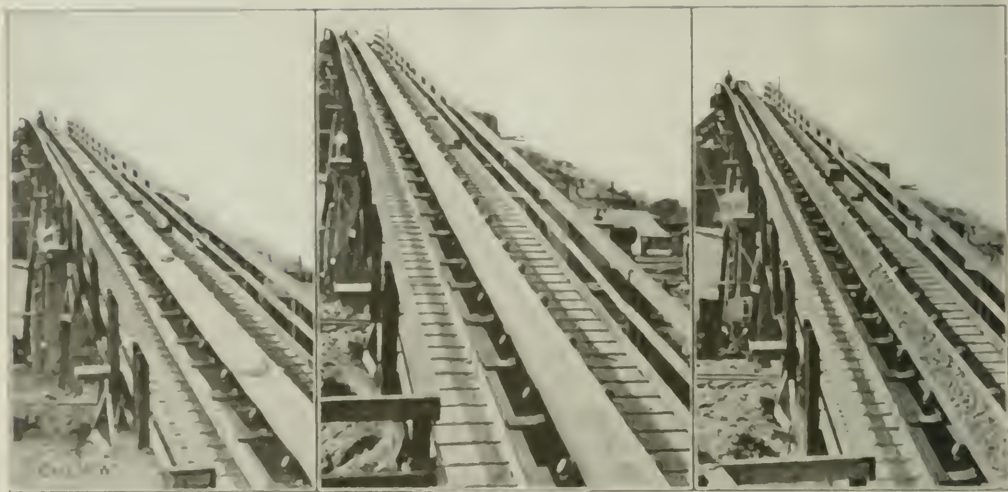


FIG. 1. BELT CONVEYORS AT HELL GATE BRIDGE, HANDLING CEMENT, SAND AND STONE

The receiving dock for materials at Ward's Island is [illegible]. The loose materials are unloaded from the scow into a receiving hopper on the upper deck of the dock, by a derrick equipped with a grab bucket, located on the dock. The belt is fed by a chute from the hopper. The bags of cement are lifted from the scow in sling loads by means of a gasoline hoist on the pier. Four men, working two and two, unloosen the slings and place the individual bags on the belt. As many as 1500 bags per hour have been handled in this manner without [illegible].

FIG. 2. TRIPPER [illegible]

slings; two to place the bags on the belt; one to operate the tripper, and 12 to 15 men in the cement-storage house.

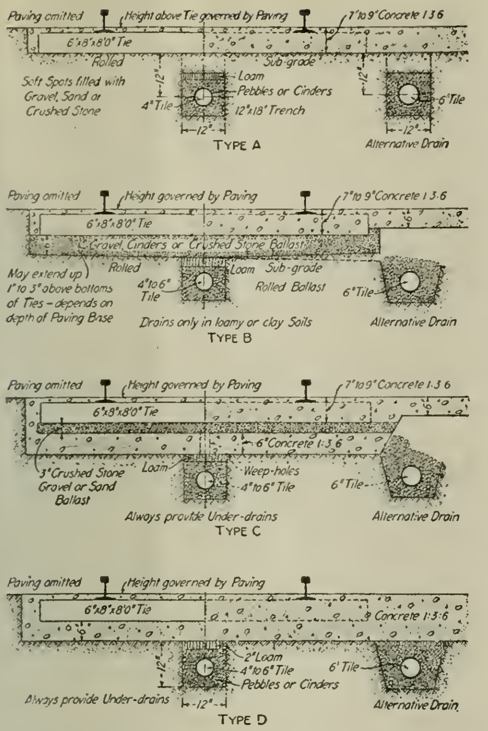
At Randall's Island the scheme of unloading is essentially the same, but instead of having a separate hoist for the cement, the one derrick on the dock unloads all materials. To handle cement [illegible] of the scow, the grab bucket is lowered into the scow and about 12 bags placed on it and lifted to the deck. At this place, also, a second belt, 18 in. wide, runs from the storage piles to the concrete mixer.

The conveyors were furnished to the Patrick Ryan Construction Co., New York City, by the Robins Conveying Belt Co.

Track Foundations in Paved Streets

The four types of street railway track foundation shown in the drawings herewith were recommended by the Committee on Way Matters of the American Electric Railway Engineering Association at its recent convention. It is reported that these designs were evolved after study of all [illegible] factors.

Type A is for moderate traffic of cars up to [illegible] tons and for [illegible], such as [illegible]. Type B is for [illegible] heavy traffic, and for heavy [illegible]



FOUR TYPES OF TRACK FOUNDATION IN PAVED STREETS

(Recommended by the Committee on Way Matters of the American Electric Railway Engineering Association.)

of cars up to 35 tons. Types C and D are for heavy water-retaining soils and uncertain made ground, with heaviest traffic and cars. Surface drains are to be provided in all cases.

Some Neglected Points in the Theory of Adjustment of the Engineer's Transit

By J. A. Kitts*

The writer outlined in the Engineering News, of July 9, 1914, a method of using and adjusting the wye-level, based on the operation of maintaining the vertical axis of the instrument precisely vertical. In using the transit, it is also essential for successful operation that the vertical axis be kept vertical (operation (1) following)—as the horizontal circle needs be horizontal to measure horizontal angles. The vertical axis is necessarily made perpendicular to the plane of the horizontal circle by the instrument maker.

It being shown by application of operation (1) that the vertical axis can be made vertical with fine precision and quite simply even though the plate or telescope bubble tubes are out of adjustment, the adjustment of all the parts is greatly simplified and facilitated and, as far as possible, made independent of each other. The precision of this operation, as also that of any method of adjustment, depends on the spindles and bearings fitting properly, being circular in section, and the outer and inner spindles being concentric. This provides an index to a defect in the spindle.

It will be observed that only one bubble tube is necessary on the complete transit, that on the telescope. One bubble tube on the plate is quite sufficient for convenience in the operation of leveling the instrument and should be placed at right angles to the telescope bubble tube.

In a theoretically perfect transit instrument the following specifications obtain:

(*a*) The inner and outer spindles, horizontal circle and verniers are concentric.

(*b*) The spindles or vertical axes are perpendicular to the plane of the horizontal circle.

(*c*) The horizontal axis is perpendicular to and intersects the vertical axis.

(*d*) The line of sight coincides with the optical axis, is perpendicular to the horizontal axis and intersects the horizontal and vertical axes.

(*e*) The tangential axes of the plate bubbles are perpendicular to the vertical axis.

(*f*) The tangential axis of the tesescope bubble is parallel to the line of sight and optical axis of the telescope.

(*g*) The cross-hairs are horizontal and vertical respectively and intersect on the optical axis.

(*h*) The plane of the vertical circle is perpendicular to the horizontal axis. The vertical circle is concentric with the horizontal axis, and the vernier reads 0° on the vertical circle when the line of sight is horizontal.

(*i*) The circles are graduated uniformly.

Physical changes take place in the instrument, usually on account of rough usage, and it is necessary to test the adjustments often. The following method of adjustment has been found to facilitate a sometimes tedious process.

Adjustments

(1) *Make the vertical axis vertical.*

Bring the plate bubbles to the center over both pairs of leveling screws. Set the vertical circle at 0° and bring the telescope over one pair of leveling screws. Note the end of the bubble near the eyepiece. Revolve 180° in azimuth and again note the eyepiece end of the bubble. Bring the end of the bubble to the mean position over both pairs of screws. The bubble will then remain in the same position for any angle about the vertical axis and the vertical axis is vertical. It will then be observed that the plate bubbles remain in the same position for any angle about the vertical axis, and either of these bubbles may be used instead of the telescope bubble. The telescope bubble, however, is the more sensitive.

(2) *Test the inner and outer spindles for eccentricity.*

Make the vertical axis vertical by (1). Hold upper plate and turn lower plate through a complete revolution. If the bubble remains in the same position for any angle of the lower plate in reference to the upper plate, the spindles are concentric. If not concentric, the correction should be made by the instrument maker.

(3) *Adjust the plate bubbles.*

Make the vertical axis vertical by (1). Adjust the plate bubbles to central position. The bubble will then remain in this position for any angle about the vertical axis.

*Until recently with the Isthmian Canal Commission, Panama Canal.

(4) *Make the horizontal axis of the telescope perpendicular to the vertical axis.*

Make the vertical axis vertical. Sight on a well defined elevated point, telescope level. Depress the telescope and establish a point at about 100 ft. from the instrument. Repeat, telescope inverted, and establish a point beside the one first established. The bisector of the line between these two points is in a vertical plane passing through the elevated point and the vertical axis. Maintain the vertical axis in a vertical position and adjust the horizontal axis until the line of sight remains in this plane.

(5) *Make the horizontal axis perpendicular to the vertical axis by means of the striding level.*

Make the vertical axis vertical. Set the striding level on the collars of the horizontal axis. Note the end of the bubble near the fixed end of the striding level. Reverse ends of the striding level and again note end of bubble at the fixed end. Maintain the vertical axis vertical and adjust the horizontal axis, bringing the bubble to the same position. The horizontal axis will then be horizontal.

The bubble of the striding level may then be adjusted to a central position, although the accuracy of the horizontal axis adjustment does not depend upon the striding level being in perfect adjustment but depends upon the principle of reversion, it being essential that the vertical axis is kept vertical by operation (1).

(6) *Make line of sight perpendicular to the horizontal axis.*

Make vertical axis vertical. Sight on distant well defined point (telescope erect). Transit telescope and establish foresight. Repeat (telescope inverted). The bisector of the line between the two points established is in a vertical plane through the backsight and the vertical axis. Adjust vertical cross-hair, bringing it into this plane. See that the vertical hair follows a point when the telescope is rotated in altitude.

(7) *Make the horizontal crosshair pass through the optical center.*

Make the vertical axis vertical. Level the telescope approximately. Establish a point on a vertical surface about 300 ft. distant and another at about 25 ft. distant (telescope erect). Invert telescope and sight on the farther point and check on the nearer point. Adjust the horizontal crosshair to the mean position. See that the horizontal crosshair follows a point when rotating in azimuth.

(8) *Adjust verniers of vertical circle.*

Make vertical axis vertical. Set vertical circle at 0° and establish a point at about 300 ft. Set the vertical circle at 180° and establish a point above or below the other, as the case may be. The bisector of the line between these two points establishes a horizontal line through the horizontal axis of the telescope. Sight on this point and bring the vernier to 0° or 180°.

(9) *Make telescope bubble tube parallel to the line of sight.*

Make the adjustment supplementary to (8), using the same point determining the horizontal line of sight, and adjust the bubble to the center of the tube.

Accuracy in all adjustments depends upon repetition and judgment in choosing distances.

Bulkheads for Boston Dry Dock

In the preparation for the new dry dock in Boston harbor (ENGINEERING NEWS, Apr. 2, 1914, p. 709), the site was paralleled on north and south by large bulkheads, which are to be joined at their outer ends by a cofferdam to inclose the dry-dock area. Each bulkhead is made up an earth fill between timber bulkhead walls of two types.

The outer wall, about 7500 ft. long, consists of 45-ft. to 50-ft. oak piles, braced by oak spur piles, to which are bolted 8x10-in. wales, holding 4-in. yellow-pine sheeting, 30 ft. long, driven to grade 14 ft. above M. L. W. The sheeting is square-edged and is spiked to the wales. All pile bolts are $1\frac{1}{4}$ in. diameter, and wale and stringer bolts are 1 in. in diameter. A detail is shown in Fig. 2.

FIG. 1. BULKHEADS AROUND DRYDOCK SITE, BOSTON HARBOR

The inner bulkhead wall, 4000 ft. long, and facing the site of the dock, is constructed of spruce piles of the same dimensions as the outer bulkhead piles, similarly braced and sheathed with 4-in. grooved yellow-pine sheeting, fitted together with $1\frac{1}{4}$x6-in. spruce splines. No preservative treatment of any kind was used on the piles or sheeting.

A noteworthy feature of both bulkhead walls is the relieving platform of 4-in. oak plank, which is slung from the top stringer of the bulkhead by 2x6-in. oak straps at about the low-water line. The platform is about 4 ft. wide and extends around the entire length of all the bulkhead walls.

The total area to be inclosed is about 47 acres and

some of the earth fill is to be dredged from the dry-dock site in getting the bottom there down to grade, while the remainder will be dredged from a new channel leading to South Boston wharves.

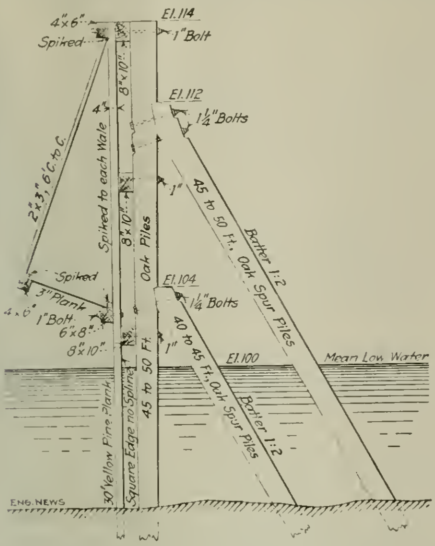


Fig. 2. Section through Outer Bulkhead Wall, Boston Dry Dock

(Note relieving platform.)

The work is being carried out by the H. P. Converse Co., of Boston, under the direction of the Directors of the Port of Boston, with Frank W. Hodgdon, Chief Engineer.

Notes from the Experience of an Old Surveyor

By A. W. Bedell*

Measuring Lines—Probably the most reliable method of measuring existing land boundary lines is to set a station within taping distance of every point to be located and measure angles and distances to each of these points, any of which can then be relocated exactly later. Stadia methods will be found as accurate as taping in the case of slight bends in the boundary line, in locating which some error is allowable in the bearing, provided the angle between boundary and traverse lines is small.

There is one disadvantage in this method—from which, however, most of the others are not free—that no matter how good the traverse closure may be, a mistake in one of the side shots will affect the boundary and pass undetected unless all measurements are checked in the field.

Points on a boundary that are inaccessible or difficult to measure to, can often be located by intersection from two stations. This is reliable if carefully checked, but the triangle should be well proportioned with no angle less than 30° or 40°.

Angle Measurements—There are several ways of measuring angles which are all good so long as consistently used, and the notes should show clearly what is done. Some surveyors measure interior angles only. On a closed figure these should total 180° × (number of angles — 2). Others record the deflections from the line of the backsight produced forward. In this case counting exterior deflections as plus and interior (reëntrant) ones as minus, the algebraic sum for the closed traverse should total 360°.

In all these cases the backsight is set on zero. A common way is to record readings as angles to right or left of backsight or as deflections to right or left of the backsight line produced (Fig. 2).

The bearings of the courses can be figured continuously, checking them with a needle, by considering northeast courses plus (clockwise); left readings will be minus and right ones plus. In a closed figure the algebraic sum of all plus and minus readings should be zero or a multiple of 180°.

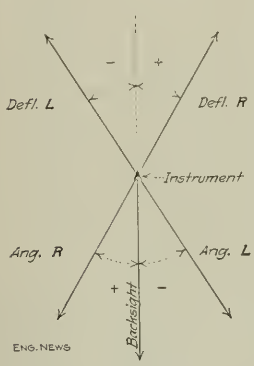

FIG. 1

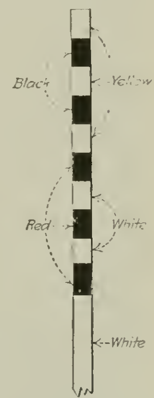

FIG. 3

The most convenient way is to carry the azimuths on the instrument by setting the vernier on the forward azimuth of a line, and backsighting with the telescope plunged; the plate is then always oriented. To do this, the collimation adjustment must be good, or this error accumulates. The advantages of this method are that the azimuth of a line is always known, and that the needle, therefore, gives an instantaneous check. Where greater accuracy is needed angles must be repeated.

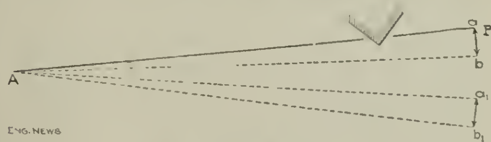

Fig. 2

Sighting around Obstacles—Very often an obstacle on a line prevents a direct sighting between points. In such cases an equal distance may be offset on each side of the point sighted to, and the angle read at each and bisected. A quick way of getting a backsight or zero when an obstacle intervenes was devised by F. R. Raven, of Glen Cove, N. Y. A stick of any convenient size (a_1 b_1 in Fig. 2) is held somewhere near the backsight point in view of the transit and square with the line of sight AB.

*Chappaqua, N. Y.

The circle is clamped with zero on a_1, the end of the stick pointed to the point, and the upper plate is shifted and set on the other end b. The stick is then moved until the [illegible] the required point B (invisible); and without disturbing the vernier reading, the transit is [illegible] on the other end [illegible], whereupon the zero will be in line with the invisible point.

ERRORS FROM DIFFRACTION—There are times when an obstacle is so close to the line of sight that it blurs, although it may not obscure, the object. The writer cautions surveyors against using such sights, for although he has never seen it mentioned elsewhere, it results in errors from diffraction. This is the property of light which causes rays to deflect when passing the edge of an object.

CHECKS—It is a decided advantage to check all measurements when possible, the certainty derived more than compensates for the extra time. Angles may generally be checked by compass readings; stadia sights give a check on distances.

It is best not merely to put check marks in the notes, but to record all readings; they may be useful to refer to if discrepancies arise.

The writer has constructed a range pole with the upper foot subdivided as shown in Fig. 3. Distances are read to all points to the nearest foot at the time of the foresight.

STATION MARKS—Sixtypenny nails as transit points will last longer than soft-wood stakes, and are more convenient to carry and to drive. In fact stakes cannot be used at all in frozen ground. Some surveyors place three stones around each transit point, which makes it easy to locate them even after several years, while a guard stake standing beside the hub might soon be burnt away.

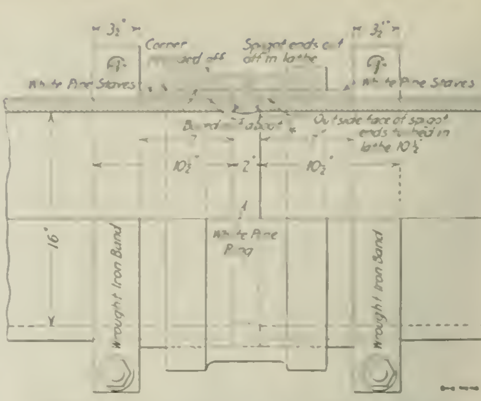
There is nothing that will last longer than stone, and whenever possible it is well to use an outcrop for a station by cutting a deep cross at the survey point.

Important stations on roads, if likely to be disturbed, can be referenced by distances to two or three permanent marks. These may be tacks in trees or fence posts. Only copper tacks should be driven, for nobody uses these except surveyors, while steel tacks might easily be confused with the great number used for bill posting. Moreover, steel will soon rust out, even when galvanized.

When a tack or nail is put in a tree, the spot should first be blazed. This serves to identify the mark, but it may further be of great value in later years by determining the time at which the mark was made. This may be found by cutting out a section of the wood and counting the annual rings of overgrowth. It may not be generally known that a tree trunk does not gain in height after the first few years' growth. Yearly accretions merely add to the diameter. A nail driven into the wood, therefore, eventually becomes covered over, but does not change its position.

NOTES

Wood Insulation Joint for Water Mains—The type of joint shown in the [illegible] has been in use in Providence, R. I. [illegible] since 1897. [illegible]



WOOD INSULATION JOINT FOR WATER MAINS, PROVIDENCE, R. I.

Other details are given in the sketch. Very little trouble from electrolysis is experienced in Providence. Where electrolysis has occurred service pipes and meters have been examined and the cause of the trouble removed or the trouble reduced. All the large 16-in. insulation joints are on the high-pressure fire-service mains.

A Tilting Base for Flagpoles—Erecting, inspecting and painting the tall flagpoles commonly used on buildings and in parks, etc., is costly and difficult. The steeplejack is eliminated and the cost reduced by a new type of pole support in which the flagpole is socketed in a tilting base so that the pole can be lowered to a horizontal position and the painting or rigging attended to without difficulty.

The socket is in two parts, bolted together, so as to firmly clamp the butt of the pole for its entire length. It carries counterweights at its lower end and is mounted by trunnions

The Protection of Watervliet, N. Y., Against Storm Waters

By F. J. Keis*

SYNOPSIS—The City of Watervliet, to protect itself from periodic inundation by water draining off the rolling land above, has created two reservoirs with outlet works to impound temporarily the storm rainfall, spring freshets, etc., and to allow the floods to pass off at a rate within the capacity of the channel provided. The reservoirs will normally be dry.

THE WATERVLIET STORM-FLOOD PROBLEM—The City of Watervliet, N. Y., five miles above Albany, is on the west bank of the Hudson directly opposite Troy. Along the westerly limits of the city, the hills rise abruptly some

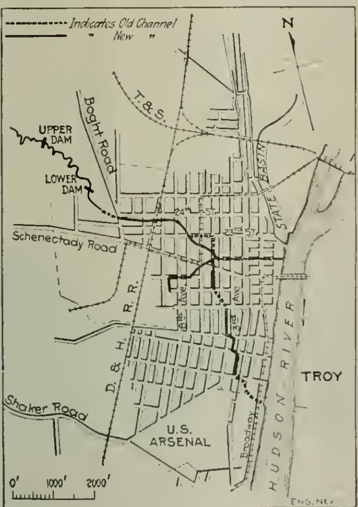

FIG. 1. WATERVLIET SKETCH MAP, SHOWING DRY RIVER AND NEW STORM SEWERS

200 ft. and continue back to the ridge dividing the Hudson and Mohawk watersheds. Practically the entire watershed is under a high state of cultivation and is well and rapidly drained. The soil is mostly clay and quite impermeable. The country is open and undulating and the aforesaid conditions, together with the steep gradient of the watercourses, causes the water from melting snow and ice and from even moderate storms to be discharged so rapidly that the capacity of the channels below is overtaxed. The stream which has caused the trouble in Watervliet is the so-called Dry River, and the works herein described have been built for its control.

Dry River entered the northwestern section of the city and flowed through a winding channel in a general southeasterly direction, discharging into the Hudson River at the Watervliet Arsenal. Beyond the city it winds through the hills and for about a mile west of the limits runs through a deep and precipitous gorge which eventually opens out upon the comparatively level city plane, where the stream's gradient is light.

Many culverts had been built to carry the city's streets across the stream, and its waterway had become more or less obstructed by structures arranged to meet individual requirements. In the summer the stream became practically dry except in pools, which served as catch-alls for refuse, garbage and sewage. The filth accumulated between storm intervals was deposited over the streets and in the cellars during the frequent freshets which occurred often with little warning. During the winter months when heavy ice formed, the culverts would clog, force the water over the streets and add to the already intolerable conditions.

A tributary of Dry River, known as "Gas-House Creek," emptied into it about a half-mile from its mouth. Like the main stream, it was an eyesore, a source of constant expense and annoyance, and a danger to the public health.

Various schemes for improvement had been discussed and some had been tried, but these were local in nature and limited in their scope. They generally succeeded in bettering one place only at the detriment of another. In 1910, after considerable agitation on the part of certain civic organizations, it was determined to devise a

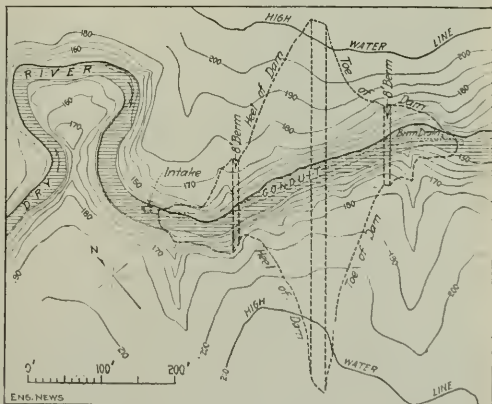

FIG. 2. PLAN OF EARTH DAM

comprehensive plan for the permanent improvement of the stream. The Storm Sewer Commission was authorized by the state legislature, and it engaged as consulting engineers, Solomon, Norcross & Keis, of Atlanta, Ga., to make the necessary investigations.

IMPROVEMENT PLANS—Detail surveys and study of local conditions showed that it was most feasible to create two reservoirs in the narrows of Dry River, west of the city, to release the impounded waters at moderate rates of flow and to carry the stream in a reinforced-concrete conduit built in part along the old stream bed. The two reservoirs would remain empty except in times of freshet, and their principal function would be to retard the ex-

*Solomon, Norcross & Keis, Engineers, Watervliet, N. Y., and Atlanta, Ga.

and flood discharges. Gas-House Creek was to be turned into a [illegible], without control works, and led to the [illegible]. A [illegible] was planned to the Hudson, the old bed of the stream below the point of departure being used for a large concrete sewer to carry off the

slope is paved with old street blocks to a point 10 ft. above the berm, while the downstream slope pavement is stopped at 15 ft. above the foot of the slope.

A reinforced-concrete core wall 6 in. thick, on a base 3 ft. wide, was carried down into the rock. The core wall

Fig. 1. Maximum Section of Upper Dam, Dry River Improvement

storm water formerly entering the stream from adjoining streets.

Upper Dam—The upper dam is an earth fill across the upper end of the rock gorge, where the valley broadens out into an open basin. At the dam site the gorge is about 40 ft. wide at its bottom, but increases to a width of 300 ft. at crest elevation, 85 ft. above the bottom. The crest of the dam is 20 ft. wide. The upstream slope is 1 on 2½ and the downstream 1 on 2. Berms, 8 ft. wide, are built at [illegible] on both slopes and [illegible] carry the drainage to the toes of the slopes. The upstream

was built in lifts of from 6 to 8 ft., the concrete work being carried on simultaneously with the fill. Special effort was made to obtain a tight bond between old and new concrete work by means of steel plates.

The earth for the first 50 ft. of embankment was hauled in 4-yd. side-dump cars over a track laid along the edge of the gorge and dumped so that it would slide down onto the fill. [illegible] distributed the material in 6-in. layers, after which it was thoroughly rolled by a steam roller and sprinkled. After the 50-ft. elevation was reached, all material was hauled from the bor

Fig. 3. Upper Dam and Intake Tower, Dry River Improvement, [illegible], N. Y.

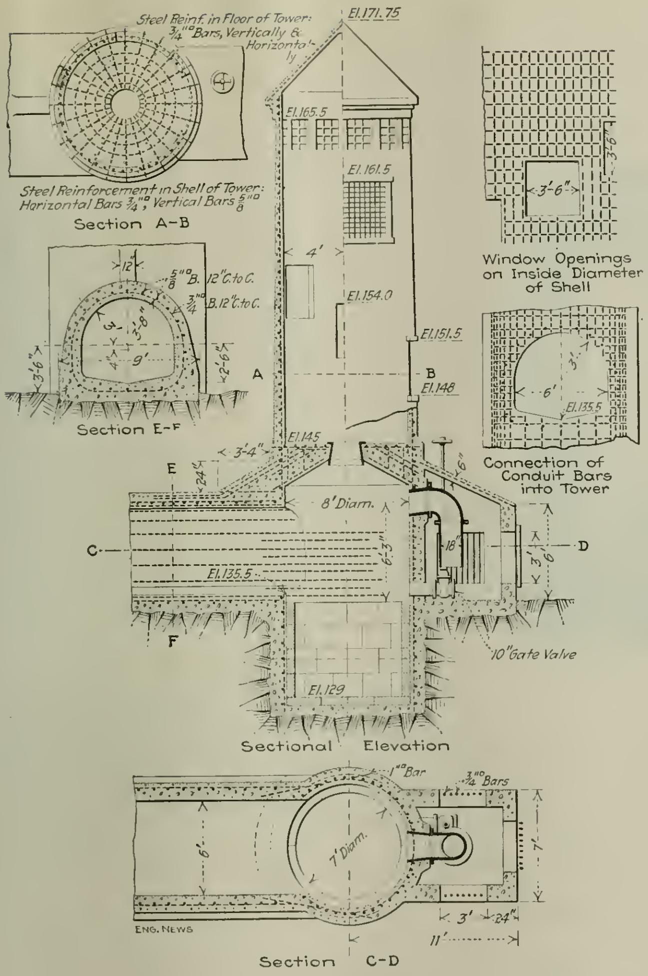

FIG. 5. DETAILS OF REINFORCED-CONCRETE INTAKE TOWER

row pit in wagons and wheel scrapers and compacted as before, the greatest care being taken in the placing of the material for the dam.

INLET TOWER—In order to avoid any moving mechanism and make the operation of the discharge works independent of manual control, a system of orifices, adequately protected against freezing and clogging, was deemed to be best suited for the purpose of regulating the flow of impounded waters. Accordingly, these orifices were placed in a circular tower of reinforced concrete in the positions shown in Figs. 4 and 5. The smallest opening, 12 in. in diameter, is intended for the minimum summer flow. In winter, the 12-in. valve will be closed and the normal flow will be discharged through the 18-in. opening in the side of the tower. When the flow increases above the capacity of this opening, the water will rise to the grated openings set spirally into the tower walls. These openings are five in number and extend to near the top of the tower, where they are capped by a ring of smaller openings extending around the entire circumference. The orifice in the tower floor, which is located above the 18-in. side opening, discharges the water into a granite-lined well, whence it passes downstream to the second reservoir. As the stream flow increases, the reservoir fills until such time as the discharge through the tower equals the rate of runoff. Then the water level remains constant and later it begins to recede. A study of past storms indicates that the reservoir will seldom be filled to any of the higher levels longer than 48 hours.

SPILLWAY FOR UPPER DAM—A depression in the crest of the hills inclosing the upper reservoir forms a natural spillway. This depression opens out into a small tributary of Dry River which enters the stream about a quarter mile below the dam. In the event that the reservoir should ever become filled, the water would flow through this channel to a concrete spillway wall extending across it, discharge upon a paved semicircular apron and be carried thence through an open concrete-lined canal section to the small tributary mentioned.

LOWER DAM—About a half-mile below the earth dam, near the end of the rocky gorge through which Dry River runs and not far from the upper edge of the city plane, is a reinforced-concrete deck dam, 25 ft. high and 105 ft. along its crest. A spillway 72 ft. long is centered on the crest length.

The small reservoir created here receives the discharge from the tower and conduit at the upper dam. The flow from here is regulated in the same manner as at the upper works, though the orifice structures do not much resemble each other. There is, first, a low-lying concrete box with three large orifices for ordinary flows; instead of a tower rising above this outlet chamber, a second orifice box is placed on the deck at a higher level, greater and greater outflow area becoming available as the reservoir level rises.

The ordinary flows are led from the smaller outlet chamber through a 22-in. steel pipe running downstream 1200 ft. to the concrete conduit and entering it about 200 ft. beyond the entrance. The pipe is protected from freezing by lagging on exposed sections. The idea in using the pipe was to prevent the shoals between dam and conduit from freezing over and furnishing ice to choke the sewer intake at spring breakup. The freshet water passes through the deck orifices and is discharged into the stream bed, along which it passes until received by the main conduit.

SEWERS—The concrete conduits are mostly of standard horse-shoe type and range from 6½ to 8½ ft. in diameter. The thickness of walls, arch and floors and amount of reinforcement vary according to the depth and nature of the trench, but for any one diameter of sewer the same steel forms (Blaw) were used and all changes were

[illegible] In that part of the [illegible] through solid rock a special section [illegible] [illegible]. This section had [illegible] vertical [illegible] walls, all [illegible] sloping toward the middle, and a [illegible] arch for the [illegible].

[illegible] below the [illegible] dam, the [illegible] was started. The entrance was formed by the usual

[illegible] wing walls converging on the conduit. The stream bed was dammed [illegible] by a small earth fill.

The diversion from the old stream bed is at the head of [illegible] St., some three-quarters of a mile above the old mouth. In carrying the line westward through this street, the [illegible] [illegible] in 1830 [illegible]. At the [illegible] inlet the arch line of an $8\frac{1}{2}$-ft. sewer, so that a special section had to be substituted to avoid a bypass. The invert grade was maintained and a twin-box culvert [illegible] ft. in height was substituted and built so that from the [illegible] both ends sloped and converged into the standard section. This is shown in Fig. 7.

The channels of both streams being located for the most part through city streets and developed property in the most desirable sections of the city, are now being rapidly filled in and reclaimed, and all vestige of the streams is rapidly disappearing. During the heavy spring freshet of 1913 the system, although still incomplete, worked very satisfactorily and not a street was [illegible].

Cost, Etc.—The total cost of the work above described was $165,000. It was planned and executed under the direction of Solomon, Norcross & Keis, the writer being in active charge. Leary & Morrison, of Fairport, N. Y., were the contractors.

Fig. 7. Old [illegible] Culvert under Erie Canal, Waterford, N. Y.

conduit is $8\frac{1}{2}$ ft. in diameter, but [illegible] gradually [illegible] [illegible] to $9\frac{1}{2}$ ft. to accommodate the city storm water and the flow of [illegible] Creek, which is received at the foot of [illegible] St. This [illegible] stream is intercepted by a [illegible] [illegible] [illegible] so that much of the [illegible] [illegible] of the city, [illegible].

[illegible] the Hudson, [illegible] [illegible] Erie Canal. The [illegible] [illegible]

The Effect of Hydrated Lime on volume change and strength of portland-cement mortars and concrete has been reported upon by Henry S. Spackman, of Philadelphia, to the National Lime Manufacturers' Association, and the results published in Bulletin No. 15, [illegible], of that Association. Tests were made on mortars and concretes [illegible] with varying percentages of lime [illegible] and with the pieces exposed under water and in air outdoors, and alternately in water and air. [illegible] was made to note the expansion of the pieces with variation in moisture content. Curves for all the tests are shown in the bulletin. We give below only the conclusions drawn by the author.

Variation in moisture content as well as change in temperature affect the volume of the test pieces. [illegible] contact with water other than the variations in the air [illegible] a marked tendency to [illegible] of the test piece [illegible] up to and beyond the [illegible] period, where the test piece is in constant or frequent contact with water, the general tendency is toward expansion as [illegible] [illegible] with the [illegible] [illegible] [illegible] [illegible] [illegible] cases by [illegible] [illegible] contact with water and [illegible] [illegible] with water, the [illegible] of hydrated lime [illegible] [illegible] [illegible] [illegible] contraction when the test pieces are [illegible] exposed either to water or dry air, [illegible] [illegible] [illegible] [illegible] [illegible]

[illegible] test piece is [illegible] and [illegible].

A Novel Dry Reservoir Project

The control of the flashy little Dry River, whose sudden floods have done so much mischief at Watervliet, N. Y., in past years, is one of the interesting pieces of unusual design in hydraulic engineering which have been carried to completion this year. To many the idea will seem natural, as shown in the description of the Dry River improvement elsewhere in this issue, to build works which will store up the freshet waters and automatically let them out at moderate rates of flow within the capacity of the channels. Yet the only other actual employment of the basic scheme that we have seen in municipal improvement work in this country is at the Paxton Creek flood-control works in Harrisburg, Penn. (described in Engineering News, Feb. 17, 1910). The structures and general layout in the two cases are, of course, quite unlike. The same idea, also, is involved in the flood-prevention schemes which involve dry reservoirs scattered in the headwaters of a large stream such as are proposed for the control of the Miami River above Dayton, Ohio.

The Use of Timber on the New York Subway Work

The average New Yorker hardly appreciates the magnitude of the work on the new subway system, because that work is carried on almost wholly beneath the street surface. When the first subway lines were built, the work was carried on in open cut and the streets on which the lines were located were closed to all traffic for long distances, in some cases for many months. The interference with business caused a public demand that in future subway work the street surface must be maintained and kept open to traffic during construction. The original line on lower Broadway was thus built and the same method is being pursued on the new subway lines now under construction in Manhattan and on many of the streets in Brooklyn.

Elsewhere in this issue, F. Lavis describes the methods of timbering used in supporting the street surface on the New York work. The magnitude of this task is one little appreciated save by those directly connected with the work. At Canal St. and Broadway, for example, the subway excavation is a pit some 60 ft. deep and 100 ft. in width. Mr. Lavis estimates that the temporary timbering of the subway cut for 13 miles on Broadway, Lexington Ave. and 138th St. alone has required some 70 million ft. b.m. of timber; and at least twice as much more will be required on the work still to be done.

A rough computation of the cost of this timber and the cost of cutting and placing it shows that this feature alone of the new subways involves an expenditure of many millions of dollars.

It is to be further noted that this method of construction, filling the excavation with a forest of timbers, has made it necessary to do practically all the excavation by hand, and has prevented the use of modern excavating machinery, thereby adding largely to the cost of the work.

No doubt, the construction methods adopted are the best possible under the circumstances; but it is at least an interesting speculation whether a large saving in the cost of construction might not have been made had it been possible to let the work in stretches of five or six miles to a single contractor on broad specifications which would have allowed the development of a type of structure and also of an economical method for its construction.

In Buenos Aires, the capital of the Argentine Republic, a subway line has recently been completed by the open-cut method. The contractors were allowed to work on only three blocks at a time; on one, excavation was being done by a steam shovel, loading the excavated material into standard-gage cars, which were hauled back through the completed structure and up an incline to the surface-car tracks. On the next block the structure, of steel frame and concrete, was being erected and on the third the street surface was being restored. No one block was kept open more than three months, though it should be noted that there was no rock to be excavated. In this case, the contractor (the operating company) both designed the structure and executed the work.

Of course, there are many sections of New York where no interruption at all of vehicle traffic is permissible; but there are many sections where half of the street could be given up, and many others where, were it not for previous experience, the open-cut method might be used.

It is also worth noting that while most contractors on the New York work complete excavation over a large part of their section before beginning to build, others push the construction work simultaneously with the excavation. On Section 1 of Route 5, for example, there are at all times men putting down the street decking, taking out the first lift, underpinning buildings, etc., followed by others completing the excavation, laying the waterproof floor, erecting the steel, concreting, waterproofing and backfilling.

Had this latter plan been more generally followed, it would probably mean a shorter time between breaking ground and completion of any street block, and apparently some economy in the use of timbering, since more of it could be used over and over.

The Fascination of Railway Location

Was there ever any sort of engineering work which gained such a grip upon its devotees (we use the word advisedly) as the work of railway location?

One of the oldtimers, who played an active part in engineering back in the '80's when more civil engineers were engaged on railway location and construction than in any other field of engineering work—a man who served under Wellington in Mexico—confessed the other day: "I know that some engineers when they have a holiday

or vacation like to go off in the country somewhere and play golf; but when I want to take a vacation and get the most enjoyment out of it, I go off in the wilderness somewhere and locate a railroad line."

We think that there are thousands among our older readers who look back with fond recollection on their years of work in the field ahead of a construction gang. With all the hardships and not seldom the dangers that accompanied the life of the locating engineer, there was a keen fascination about the work. The study of the topography so as to work out the best line through a difficult country to satisfy required conditions was as much a challenge of the engineer's skill as a game of chess or billiards. This was, without doubt, one of the reasons why, notwithstanding the long working hours, the rough fare and the small rate of pay compared with the responsibility carried, there were plenty of railway-locating engineers who stuck to that work in preference to any other field of engineering as long as there was location work to be done.

Hydrated Lime in Concrete

Hydrated lime as an adjunct to portland-cement mortar and concrete is no new thing. Various well known experimenters have shown that small additions of hydrated lime to cement mortars render them practically impermeable to moisture, have no material effect upon their tensile strength and much increase the plasticity of the mortar over that composed of cement and sand alone.

These very commendable characteristics of hydrated lime have been accepted by engineers without much thought as to their application to concrete work. In fact, the makers of hydrated lime, themselves, have not considered it worth while to emphasize any of them except the waterproofing feature, which is unfortunate from a selling viewpoint, because there are many other equally effective ways of making concrete water tight. It is doubtful, however, if one engineer in twenty, accustomed to the use of concrete, has an adequate appreciation of the possibilities of hydrated lime, due to those very qualities which many experimenters have reported.

In two fields of concrete work there would appear to be a distinct advantage in using hydrated lime, in concrete which is to be delivered by the spouting method and in concrete roads. In the former case it has long been a cause for complaint that while spouting is a most, perhaps the most, economical and effective way of getting concrete to the forms, unless the tower is exceedingly high or the horizontal distance quite short, the low angle of slope requires an excessively wet concrete to insure easy spouting, and every experienced engineer knows that an excessively wet concrete is a dangerous concrete. It seems probable, however, that a proper admixture of hydrated lime would give the concrete a "buttery" consistency, a certain slipperiness, as it were, which would lower the friction coefficient and permit of its spouting on a lower slope. Some few attempts to utilize this advantage have been successful, but they have only been extensive enough to show that there is here a field for investigation and practice well worth pursuing.

The desirability of hydrated lime for concrete road work was well advocated at the recent Road Congress at Atlanta by a lime manufacturer, Charles Warner, of Wilmington, Del. A point in favor of the use of lime in road concrete emphasized by Mr. Warner is the effect of the hydrated lime in reducing the tendency to segregation in the wet mixture of cement, sand and stone, and also in reducing the ratio of the expansion when the concrete changes from a dry condition to a wet condition. This reduced expansion is doubtless a result of the decreased permeability of the concrete made with hydrated lime. The importance of reducing segregation ought to be apparent without argument. One of the difficult things in laying a concrete road is to get the mix wet enough so that it can be readily tamped into place and will form a solid mass without voids and yet not so wet that the cement and sand will separate as the water flushes to the surface. The addition of hydrated lime materially decreases the tendency of the cement and sand to separate under the screed or the trowel, and at the same time makes the mass flow more readily into place.

It might be thought that mixing the lime with the cement, even though it did not affect the tensile strength of the mortar, might alter its hardness, since lime-mortar is much softer than cement. Since there is no place in which concrete is used where extreme hardness and resistance to concussion and abrasion are of greater importance than in a concrete road surface, the probable wear of a hydrated-lime concrete road is equally important as the ease of construction. Here is something that experience alone can answer. We are informed that at least one concrete road is this year under construction with the admixture of hydrated lime; its behavior will be watched with interest by engineers.

Of course, it can readily be understood that the hydrated lime must be very thoroughly mixed with the cement to secure the results above set forth. If such thorough mixing is not secured and some parts of the mortar as laid in the completed work have a deficiency of hydrated lime while others have an excess, the strength of the work might be considerably affected. The question how practically to effect such thorough mixing is not as easy as might at first sight appear. Where mortar alone is to be used and the machine mixer is available, it will be comparatively easy to put the right proportion of hydrated lime in each batch and keep the mixer turning until the lime, cement and sand are thoroughly incorporated. The great bulk of portland cement, however, is used in making concrete and the accurate proportioning of the lime to the cement and its thorough mixing with the stone and sand are matters deserving some study.

Indeed, practically all of the advantageous features set forth above have had only limited practical proof. Theoretically and experimentally there is much to be said in favor of the proper use of hydrated lime in concrete. Therefore engineers will look for reports on the actual construction which the next year will undoubtedly bring forth.

Salt Water in Miraflores Lake on the Panama Canal: A Curious Hydraulic Paradox

A very remarkable hydraulic problem has recently been solved on the Isthmus of Panama, and solved by the remedy of experience, in a manner quite contrary to the anticipations of the engineers. The facts concerning it are briefly recited in the Annual Report of Colonel Goethals, Governor of the Canal Zone, just issued. In what

follows, we have added enough to the statements given in the report to make the matter clear to those unfamiliar with the topography of the Canal Zone.

A year and a half ago, the question of a source of water-supply for the towns at the western end of the Canal, including the terminal at Balboa, was under consideration. Various projects were considered, but the one involving the least cost of any was to take the supply from Miraflores Lake. A further advantage of this supply was that its quantity was sufficient for every requirement of the future.

Miraflores Lake is a basin a little less than a mile long, extending from the foot of the Pedro Miguel Locks (which are at the Pacific end of the Culebra Cut) westward to the head of the Miraflores Locks. The water-supply of Miraflores Lake comes from Gatun Lake through the Culebra Cut. Every time a vessel passes through the Pedro Miguel Locks, a lockful of water is discharged into Miraflores Lake, and a similar amount is, of course, abstracted from Miraflores Lake as the vessel passes through the Miraflores Locks. There are also some small streams draining into the lake, and it is, of course, possible at any time to supplement the flow into the lake from Culebra Cut through the Pedro Miguel Locks.

The surface of Miraflores Lake is 55 ft. higher than mean tide in the Pacific. There are two locks in the flight at Miraflores, dividing the lift into approximately two equal parts, although the lift in the lower lock is variable, according to the state of the tide. The extreme range of the tides at Panama is about 20 ft. Besides this, it is to be noted that the Miraflores Locks are about 8 miles inland from the Bay of Panama, on which the terminal at Balboa is located. There is practically no current in the excavated channel at sea level from Miraflores to the Bay, except such as is created by the discharge of water from the locks. The tide merely flows and ebbs; but every time a vessel passes Miraflores a lockful of water is discharged into the channel, and this amount of water, unless the vessel is locked through with the basin part full, means a prism 1000 ft. in length, 110 ft. in width, and some 28 ft. in depth at mean tide. Further than this, the bottom of Miraflores Lake is at a higher elevation than high tide in the sea-level section below the locks.

We have recited all these conditions to show that the engineers who made the decision to use Miraflores Lake for a water-supply had no reason to suspect, so far as we can see, that salt water from the Pacific would invade Miraflores Lake in any material quantity. The possibility that this might occur was, indeed, canvassed. The official report says:

> At the time that the use of Miraflores Lake water was considered, the possible objection was advanced that the chlorine content, by reason of the operation of Miraflores Locks, might increase beyond 75 to 100 parts per million. At the time, it did not seem possible that this would occur, at least for a period of years, on the assumption that intimate diffusion between the salt water admitted by the locks and the fresh water of the lake would not be rapid, especially in view of the fact that water could be pumped from one of the fresh arms of the lake. At any rate, the enormous saving that would result seemed to warrant adopting the Miraflores Lake project.

To the great surprise of all parties concerned, however, salt water from the ocean invaded Miraflores Lake at an astonishing rate, even though there was very little operation of the locks at that time. Chlorine-sampling stations were established at the lake in January, and by February it became apparent that a constant diffusion of salt water was taking place throughout the whole area of the lake, extending back into its arms. The proportion went as high as 15% of salt water. To meet the emergency, about 4000 gal. per min. was drawn from Culebra Cut above the Pedro Miguel Locks, and discharged into Miraflores Lake in front of the water-supply pumping station. This gave a supply of fresh water, but also a muddy water, due to the conditions in the cut.

It was obvious, of course, that with this large amount of salt water already invading the lake it would be impossible to use it as a source of water-supply. It was therefore abandoned, and a pumping station was set up on the Chagres River at Gamboa, requiring laying a line of 30- to 36-in. cast-iron pipe a distance of some ten miles. Before this radical action was taken, an attempt was made to clear Miraflores Lake of salt water by drawing out the water in it through the Miraflores Locks and admitting fresh water in its place through the Pedro Miguel Locks, but the results were not satisfactory.

Now comes the interesting engineering problem: How does this salt water from the Pacific gain access in such quantities and with such rapidity to this lake situated eight miles distant from the ocean, and with its surface 55 ft. above mean sea level, and its bottom also higher than the level of the ocean? The only explanation possible, of course, is the diffusion of the water in the process of lockage.

Suppose a vessel is to ascend the Miraflores Locks. She enters the lower lock and the gates are closed behind her. She is then floating in a mixture containing perhaps 75 per cent. of salt water from the ocean. The valves are then opened, and fresh water from the lake above is admitted into the lock through the openings in the bottom until the level of the water in the lock is raised to the level of the water in the upper lock. In this process of filling the lock, the salt water and fresh water are thoroughly mixed. The water in the upper and lower locks being now on the same level, the gates between the two are opened and the vessel is moved into the upper lock. While this movement is taking place, however, the heavier salt or brackish water in the lower lock flows into the lower part of the upper lock by reason of its greater specific gravity, while the lighter fresh water in the upper lock flows rapidly over the heavier water in the lower lock. In this manner, while the vessel is being transferred from one lock to the other, a considerable quantity of brackish water enters the upper lock.

The gates are then closed behind the vessel and fresh water from the lake is admitted through the bottom of the upper lock, until it is filled to the same level as the lake. By this time, certainly, the percentage of salt water in the upper lock should be reduced to a very small amount. Yet there is evidently enough there so that when the gates are opened and the vessel passes out into the lake, a considerable amount of the water in the upper lock chamber flows out with it, and is replaced by entirely fresh water from the lake.

A question of some interest is whether increased traffic will cause an increased amount of salt water in the lake. While it will cause frequent repetitions of the process above described, it will, on the other hand, bring a larger quantity of fresh water down from Gatun Lake to Miraflores, and will also discharge a larger quantity from Miraflores Lake into the channel below.

Letters to the Editor

Screw Spikes and Auxiliary Rail Fastenings

Sir—An article in your issue of July 16 describes some experiments with screw spikes and auxiliary rail fastenings on the Pennsylvania Lines, being in part compiled and quoted from Bulletin No. 165 of the American Railway Engineering Association (March, 1914). This article omits mention, as does Bulletin No. 165, of common defects in the insertion of screw spikes with Thiollier helical linings, which defects are illustrated by the full-page engraving on p. 300 of the Bulletin and of the 1914

SCREW SPIKE WITH HELICAL LINING SHOWING FAULTY POSITION OF THE LINING IN RELATION TO THE THREADS OF THE SPIKE

Proceedings of the Association. [This is shown herewith.—Editor.] These defects are the following:

1. Threading of the tie to receive the helical lining so that the helical threads are not in the same pitch as that of the screw spike threads. It is very difficult to accomplish this perfectly, and probably a slightly different threading tool is needed for kinds of wood differing in hardness and general character.

2. The helical lining engages the lower part of the screw spike. For good results, the lining should be longer, to reach from bottom of screw spike to close to the top of the tie. If the lining is of present length, the tie should be threaded only deep enough to cause the helical lining to have its top very near the top of the tie, the screw spike then being driven through and projecting below the sink in the bottom of the helical lining, and the spike threads below that point thoroughly engaging the uninjured wood of the tie. By this method, there is less tendency to lateral movement of the spike and very greatly reduced tendency for water to enter the tie and rust the spike and the lining.

3. The cut shows the screw-spike threads on the upper side of the threads of the helical lining and pulling against very much injured wood, instead of the spike threads being where they ought to be, close underneath the threads of the helical lining and pulling against them, as they are designed to do.

Apparently a screw spike inserted as illustrated has much less effective permanence than if placed in the tie without any helical lining and without the defacement of the tie by the threading for the lining. It is worth while to call particular attention to this matter, for the reason that if the screw spike is inserted without special care to start the spike threads under the helical lining, the chances are several times to one that the screw-spike thread will run on top of the helical lining, as shown.

It seems likely that a very large percentage of all screw spikes with helical linings now existing in railway tracks experimentally or otherwise have these defects.

WILLIAM HOOD,
Chief Engineer, Southern Pacific Ry.
San Francisco, Calif., Oct. 30, 1914.

Comparison of Results of Paying for Public Improvements with Bond Proceeds and from the Tax Levy

Sir—In catching up with my professional reading, I note you mention the latest financial policy of the City of New York.

For some time I have been strongly advocating a method almost exactly similar to that now adopted. In this connection a memorandum was prepared analyzing some of the arithmetical differences in the old and the new methods. A copy of such memorandum is attached. Some of your readers may find arguments which can be modified to meet special conditions in municipalities where the old methods may perhaps still be in force.

E. P. GOODRICH,
Consulting Engineer to the Borough of Manhattan.
New York City, Oct. 17, 1914.

[Presumably Mr. Goodrich's notes will interest and they may be some puzzling aspect to many of our readers. Case I shows how a modest "pay-as-you-go" plan will give a considerably larger number of "improvement years" than a heavy bond issue and also shows the relative effects of the two plans upon the taxpayer. Case II shows how 50-year bonds may adversely affect the finances of a city having both a bond and a tax limit. The memorandum follows:

CASE I

Assume 5% for interest and sinking-fund requirements on 50-yr. bonds.
Assume $1,000,000 available annually to finance public improvements.

The $20,000,000 issue of 50-year bonds would provide public improvements immediately (assumed as one year after the bonds were issued). The annual interest on this $20,000,000 at 5% amounts to the same as the $1,000,000 assumed to be annually available for improvements to be paid in cash. Thus, 20 improvements at $1,000,000 each can be enjoyed for 49 years. But if the initiation of improvements is delayed so that only one is initiated each year to the extent of $1,000,000 and cash paid therefor, improvements would be secured and enjoyed as follows:

One improvement would be secured the first year and enjoyed for 49 years.
One improvement would be secured the second year and enjoyed for 48 years, etc., etc., etc.

The 20th improvement would not be secured until the 20th year, and it would be enjoyed for only 30 years; but at the expiration of the 50-year period, 49 improvements would have been secured and enjoyed on an average of 24½ years each; while one additional improvement would have been secured during the 50th year. This makes a total of 1200 "improvement years." In the case of the bond issue, there would have been only 20 × 49 = 980 "improvement years." At the end of the 50 years, the cash method would have secured 225 additional "improvement years." This additional enjoyment would obviously have been delayed until toward the end of the 50-year period; and the question to be answered is whether the additional delayed improvements are worth more than the immediate enjoyment of a less number of improvements.

Total expenditure for improvements by bond method	$20,000,000
Total expenditure for improvements by cash method	50,000,000
Total payment by taxpayers, each method	50,000,000
Interest paid to bankers, bond method	30,000,000

COMPARATIVE EFFECT ON TAXPAYER—It is often stated, as against the cash method, that a taxpayer has the use of his money in his own business during the 50-year period; and that when he pays cash for an improvement, he is thereby deprived of certain profits which he might have made.

Assume 5% for interest and sinking fund on 50-year city bonds.
Assume that an individual taxpayer's share of an improvement was $100.

Obviously, his share of the interest and sinking-fund requirements would be $5 per annum over a period of 50 years. In other words, he would have the use of $95 of his income compounded over that period. On the other hand, if he paid $100 cash the first year, he would have the use of $100 of his income compounded annually for 49 years. The accumulations at the end of the 50-year period are easily computed mathematically by well known actuarial methods, the formula being annual sum involved × ([(one plus the interest rate) raised to a power equal to the bond period] minus one) divided by the interest rate measured in hundredths. Making these computations on the assumption that the taxpayer can compound his money at the 10% rate per annum in each case, the problem resolves itself into $95 compounded for 50 years against $100 compounded for 49 years. The totals in the two cases are, respectively, $110,572 and $105,720. There is a difference, therefore, in favor of the bond method as far as the taxpayer is concerned, of $4852 accumulation at the end of 50 years. This is a matter of only four and a fraction per cent., which is to be offset against the enjoyment of a greater number of improvements where cash is paid for them.

In this connection, it is to be recalled that the majority of taxpayers are wage earners or salaried employees, and that few of them have opportunities or the ability to compound their savings at any such rate of interest. To the large majority of taxpayers, therefore, the problem is not one of a 10% compounding, but only the interest which saving banks will pay on deposits, or which may be realized from absolutely safe investments, such as are always recommended for the man with small earning power. If the above computations are made on the basis of a 5% compounding, the results are, respectively: $19,888 accumulations if bond method is used, against $19,843 if cash is paid for the improvement. This is an insignificant item. Even in the case of a 20% compounding, the taxpayer would have accumulated at the end of 50 years only about 12% more than had cash been paid.

CASE II

Assume a 10% limit of bond indebtedness for the municipality.
Assume a 2% limit in the tax rate for such municipality.
Assume 5% as the interest and sinking-fund requirements on 50-year municipal bonds.

With a valuation of $1000, the bonds outstanding would amount to $100. The eventual interest and sinking-fund requirement would be $5, while the total taxes would be $20. In other words, 25% of the total tax rate would go for interest on indebtedness. The other 75% would normally be expended for general municipal administration. If it be assumed that the full limit of indebtedness is maintained at all times, so long as the municipality is growing at a constant rate per annum (geometrical ratio), improvements can be made through and paid for by bond issues to the extent of 10% of the yearly increase in valuation. Should this increase stop for any cause, public improvements must similarly cease. Under such circumstances, no increase can be made in the tax rate for improvements or for increase in cost of administration. In other words, the municipality is absolutely estopped from developing itself so as to bring about an increase in valuation through the effect produced by public improvements. It has throttled its own growth. Had the "pay-as-you-go" method been adopted, more improvements could have been secured in any period longer than that measured by the bond interest rate divided into 100, and, any time, the community would have been in a position to expand or contract its tax rate (within the assumed 2% limit above mentioned) as community demands required. An elastic method would have been secured with the corresponding beneficial result.

A point which Mr. Goodrich might have made is that although under his "pay-as-you-go" plan a considerable number of the "improvement years" are deferred, a considerable part of the improvements would still have many years of usefulness at the end of the period.—EDITOR.]

Questions in Building the Embankment of the Yale Bowl

Sir—The statements contained in your editorial, "The Yale Bowl," in the last issue of ENGINEERING NEWS, taken in connection with the description of the work by Mr. Atwood, in the same issue, conveying an entirely erroneous impression as to the proposed method of building the Bowl as planned by the writer. The editorial says:

The original project contemplated making the embankment a single dump, without much or any attempt at consolidation; the material was to be deposited in 8-in. layers and not rolled. The contract and specifications were actually drawn on this basis. Of some interest in the same connection is the fact that it was originally planned to build the concrete seating structure all the way up the slope, on the fill as well as on the part in cut, and this with unconsolidated fill as originally contracted for.

The following is an extract from the original specifications as drawn by the writer:

The embankment shall be built to the exact shape shown on the plans, the earth being deposited in horizontal layers not more than 6 in. in thickness, and be solidly compacted by sprinkling with water and rolling with rollers weighing at least 400 lb. per foot of length. Two or more rollers shall be used as may be necessary; one a grooved roller and the other a smooth one. They shall be used together, one following in the track of the other. The embankment on the side toward the field shall be kept "full" of the theoretical lines at least 1 ft. to permit of the earth being rolled out to the edge of the embankment, and to afford a solid foundation for the concrete slabs. The tunnels shall be constructed as soon as the embankment has been built up to the level of the top of them.

With an embankment constructed in the manner specified, the writer believed that it would be perfectly safe to lay the concrete facing directly on the sand, on the filled portion of the slope as well as on that in cut. The Consulting Engineer, however, thought otherwise and maintained that it was impossible to consolidate sand by rolling; that such an embankment could only be made solid by the action of the elements acting through several years. To meet this view, he devised a plan of concrete facing using reinforced slabs supported by reinforced-concrete girders resting on piers built into the face of the embankment; any irregularities in the facing, due to settlement, to be taken care of by, occasionally, shimming

up the grades. As it would be somewhat cheaper to place the material in 18-in. layers without rolling than by the method originally specified, the specifications were therefore changed by him to the form mentioned in your editorial.

When the Advisory Engineer was appointed, the question as to the best method of placing the concrete facing on the slope was, with several other disputed points, referred to him; whether in the form of a solid slab of concrete deposited directly on the earth, as intended by the writer, or in the form of an elevated structure raised slightly above it, as proposed by the Consulting Engineer. The decision favored the solid slab, and the Consulting Engineer thereupon severed his connection with the work.

The Advisory Engineer then made a supplementary agreement with the Contractor in which the specification for making the embankment was, substantially, the same as originally drawn by the writer except that the weight of the rollers was doubled.

In the meantime, most of the tunnels had been constructed, so that the new specification only applied to that portion of the embankment which was above them.

A comparison of the volumes of the cut and fill shows that the material in the embankment is nearly 7% more dense than that in the natural bank.

After the embankment was finished, last June, thirty benches were established around the top. Recent levels show that the greatest settlement at any of these points has been about [illegible] in., the average of the whole being about [illegible] in.

Whether any settlement which is likely to take place will be injurious to the structure is a debatable question, but it is believed, by the writer that, as the blocks are heavily reinforced to prevent cracking, and are "shingled" up the slope—i.e., each block has a 3-in. overlap on the block below—no serious injury would have ensued if the concrete facing had been completed without waiting for further settlement. He believes that the opening between blocks due to temperature changes is likely to exceed that resulting from any settlement.

CHARLES A. FERRY,
Designer of the Yale Bowl

New Haven, Conn., Nov. 18, 1914.

NOTES AND QUERIES

[illegible] In the note in "Engineering News," Nov. 12, [illegible] describing the proposed new [illegible] waterway from Chicago to the Illinois River, [illegible]. The number of locks will be eight instead of [illegible], including a lock connecting with the drainage canal at Lockport, and their total lift will be about [illegible] feet.

In the description of [illegible] in the issue of Nov. 12, 1914, p. [illegible], the address of the maker was omitted. The machine is made by the Whitman Agricultural Co., St. Louis, Mo.

Statistics of Pipe Production in the United States [illegible]

Unsatisfactory Performance of Brass and Bronze on the Catskill Aqueduct*

Many valves, pipe fittings, bolts and other metal objects large and small on the Catskill Aqueduct for New York City were made of bronze or brass wholly or in large part. These alloys were selected for objects to be exposed to corrosive influences where durability was most important because of the difficulty of replacement or inspection. Nevertheless, by far the greater number of sluice gates, valves, pipe fittings and similar objects were made of iron and steel, in accordance with usual practice. On account of the magnitude of the project, however, unprecedented quantities of bronze or brass were used—a total of nearly 3,000,000 lb. About two-thirds of the total consists of castings, and a large part of the remaining million pounds consists of forgings. The remainder comprises rolled plates, rolled and drawn rods, drawn and extruded shapes, etc. The individual pieces range in weight up to 22,000 lb. of castings, and up to 3200 lb. of forgings.

Unsatisfactory results have developed in the case of the cold-worked material (drawn or cold-rolled), and some of the smaller hot-worked pieces. A. D. Flinn and E. F. Jonson (Inspector) made the matter their special study from the time the first defects were found. The study has not up to the present indicated where the responsibility for the trouble rests, but the inspection has been very thorough and successful, every effort being made to find and eliminate defective pieces.

The word "defective," in this connection, describes pieces which appeared satisfactory when made and furnished and whose material met the tensile tests prescribed in the specifications, but which after a time developed cracks.

The larger part of the total of brasses and bronzes used on the Aqueduct consists of so called "manganese bronze." A considerable amount is Tobin bronze and other brasses or bronzes of related composition. These mixtures are of high strength, so far as shown by the standard tests, and were chosen because of the high requirement on some of the parts in question as to loads and stresses, and the necessity for using a metal which would not corrode appreciably in moist atmosphere or water.

The specifications required that manganese bronze should have:

> A tensile strength of not less than [illegible] lb. per sq.in., an elastic limit of not less than [illegible] of the ultimate tensile strength, and an elongation of not less than [illegible].

The general run of the acceptance tests was about as follows: *Castings*—ultimate strength 68,000 to 77,000 lb. per sq.in., yield-point 32,000 to 50,000 lb. per sq.in., elongation 25% to 40%, fracture granular to silky, the breaks frequently being crystalized. *Forgings*—ultimate strength 68,000 to 77,000 lb. per sq.in., yield point 38,000 to 52,000 lb. per sq.in., elongation 31% to 41%, reduction of area 35% to 47%, fracture frequently silky.

It must be noted, however, that the yield point in such material is not sharply defined as it is with structural iron or steel. Moreover, maximum service stresses were allowed by the specifications to go as high as two-thirds of the yield-point in some extreme cases.

Bearing further on the specification requirement, it is

*Abstract of statements by A. D. Flinn, Deputy Chief Engineer of the Board of Water Supply, New York City, in a recent address before the Brooklyn Engineers' Club.

to be noted that pipes were required to stand flattening the end to a separation not greater than twice the thickness of the metal, without cracking, and a piece of the pipe 3 in. long was required to stand splitting and opening out flat without cracking, in both cases after annealing.

Cracking Discovered

Cracking was first found in some bolts and rods installed in a valve chamber, not yet in service, but the examination inspired by this circumstance soon led to the discovery of quantities of cold-worked material such as large plates, bolts, rods, ladder parts, etc., which were in the storehouse awaiting installation, some having been there for months. The pieces showed cracks ranging from superficial to deep, in the cylindrical parts usually circumferential, extending part way or all the way around; a few pieces had actually broken apart of themselves. Some specimens did not show cracking on the first examination, but developed it later.

Extent of the Trouble

The trouble was first noted in cold-worked metal only. Later, however, hot-rolled rods, small forgings, plain extruded (hot) rods, etc., also showed failures "in disturbingly large quantities." The same statement applies to cold-worked brass and bronze rods which had been thoroughly *annealed*. No trouble was experienced with castings and with large forgings, and fortunately these classes cover the largest amount of the brasses and bronzes on the aqueduct.

Summarizing as to the extent of the damage: Large numbers of brass bolts (the term "brass" includes bronze) have been found cracked and broken in their packing cases after storage through a winter without ever having been stressed; others, never exposed to low temperatures and never stressed, have also been found cracked and broken. This statement applies primarily to bolts of ½- to 2-in. size, but it is also true of flat bars, plates and long rods. It applies, moreover, to ¼-in. flanged plates, carefully inspected after manufacture and found in good condition, which some months later showed pronounced cracking and worthless rivets. No brand or make of brass or bronze tested has wholly escaped. In short, the failures were so extensive and numerous (for instance, hundreds of bolts broke at one time or another under tension, heads came off, etc.) as to cause the gravest apprehension and lead to the substitution of steel for brass in a great many cases, in spite of the corrosion trouble with steel.

Attempts to Detect the Cause

Similar trouble has been observed elsewhere in minor degree, and has been studied scientifically. Martens and Heyn, of the German government testing laboratory at Gross-Lichterfelde, concluded that excessive initial stress was usually responsible, and recommended brushing the surface of suspected brass or bronze with a solution of a mercury salt, which in a few minutes would develop cracks if the surface of the brass was under great initial stress. The Aqueduct material also was found to have high initial stress in cold-worked pieces, the surface being usually in tension. But trials of the mercury test were not very satisfactory: many rods which showed no cracking from the mercury solution cracked subsequently, or other rods of the same lot cracked. Further, such a test can be applied to only one rod out of a lot or to only a small part of the surface of a piece, so that even if certain in its results it would not be useful for regular inspection.

Trials of the scleroscope were also made. This well known instrument measures surface hardness. It proved useful, but not sufficient in itself to discover whether a given lot of brass is subject to the deterioration in question. The surface of cold-worked metal being harder than normal metal, the scleroscope indications tend to show whether and how severely a piece has been cold-worked.

General Result of the Studies

A vital question which results from the above recounted experiences is whether brasses of high tensile strength can be produced in such a way as to form a reliable structural material, and what composition or other requirements must be specified in calling for such brass. An equally important question is what tests can be used to detect the defective quality of a piece with regard to the cracking above referred to. A subsidiary question is what safe working stress may be used in designing with high-strength brasses or bronzes. The engineering department of the New York City Board of Water Supply considers it impossible to answer any of these questions at the present time.

The Annual Report of the Panama Canal Operations

The annual reports of the Isthmian Canal Commission, which have appeared regularly since the United States Government assumed control of the work, are now completed with the report for the year ending June 30, 1914, just made public. The present report, in fact, is made by the Governor of the Canal Zone, Col. Geo. W. Goethals, the official existence of the Isthmian Canal Commission having been terminated on Apr. 1 last.

Under the present organization, the Governor of the Zone is in charge of the Department of Operation and Maintenance of the Canal, assisted by an engineer of maintenance and a superintendent of canal transportation, these positions being now held respectively, by Col. H. F. Hodges and Capt. Hugh Rodman, U. S. N. To carry on the remaining construction work as well as work in connection with maintenance and operation, a division of terminal construction was organized in charge of Admiral H. H. Rousseau, U. S. N. The work previously done by the Quartermaster's department and the Subsistence department, is now in control of the Supply department under Capt. R. E. Woods. Other divisions of the organizations are an accounting department and a health department. Work in connection with the civil government of the Zone is under charge of an executive secretary.

The past year has been notable for the practical completion of the construction work. The amount of concrete laid in the Gatun locks aggregates 2,067,731 cu.yd., and the average cost has been $7.21 per cubic yard. Concerning the Gatun dam, whose safety and water-tightness were the theme of so much discussion in engineering circles seven or eight years ago, the report states that seepage from the dam has been negligible. At the close of the rainy season two small streams were found issuing from the north toe of the dam in the west portion, but with the advance of the dry season these ceased entirely.

In the main portion of the dam there was no seepage of any kind apparent.

In the Pedro Miguel locks the total amount of concrete laid has been 928,326 cu.yd., and the average cost was $5.60 per cubic yard. In the Miraflores locks there has been placed 1,707,794 cu.yd., at an average cost of $5.17 per cubic yard. The entire cost of the gates for all the locks has been a little under six and one-half million dollars, of which the contractor for the gates received $5,663,000, and the balance (a little less than $840,000) was paid for inspection, painting, fixed steel, etc. The action of the gates in service has been entirely satisfactory, the leakage at the quoin and miter posts being extremely small.

The report gives information of especial interest relating to the experience with the paint with which the lock gates are covered. Great pains were taken in the specifications for the painting and in the application of the paint, three and four coats being used, the materials being red lead, graphite, United States Navy anticorrosive, and anti-fouling paint, a damp-proof paint, and a hydro-carbon mixture. An abstract of this part of the report appears in the next column under a separate heading.

The machinery installed for the operation of the locks has cost a very large sum of money. A few of the items are as follows: Gate-operating machines, $822,000; electrical appliances for gate machines, $207,000; rising-stem valves and guard valves and machines, $1,509,000; cylindrical-valve machines, $228,000; chain-fender machines, $831,000; spillway gates, $438,000; towing tracks and material, $1,182,000; towing locomotives, $527,000; hydro-electric plants, $628,000; high-power transmission line, $1,014,000. Very considerable sums must be added to these totals for the substations and other items of machinery and electrical equipment. The emergency dams above the locks at the summit level have been completed and tested. As many of our readers will recall, they are similar in general design to those used in the United States ship canal at Sault Ste Marie. They are intended to provide a means for shutting off the flow of water through the locks in case by some accident the lock gates should be destroyed in the upper lock, allowing a continuous flow of water from Gatun Lake. A test was made of the emergency dam at Gatun in May last. With a full head of [illegible] ft. of water against the emergency dam, it was found to have a leakage of [illegible] cu.ft. per second. This leakage did not produce a dangerous current in the locks and it would have been easy to close any of the lower gates in the face of the stream. It was evident, however, that the emergency dam could not be used instead of a caisson for unwatering the locks. Experiments are being made to devise a means of stopping the leakage.

Three central air-compressing stations at Empire, Balboa and Rio Grande were operated during the year, with outputs and cost as follows:

Plant	Output Cu.Ft.	Cost per M Cu.Ft.
[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]
Rio Grande	[illegible]	[illegible]

Earthquake shocks at Panama have been more numerous than in any year since the American occupation. [illegible] distinct shocks were recorded at Ancon. Two shocks during the year were severe enough to throw the recording pens of the seismograph off the record. One of these shocks caused slight damage to the new Administration Building under erection at Balboa. No other damage was done to the canal works.

The steam-shovel excavation in Culebra Cut to June 15, 1914, aggregated 110,262,000 cu.yd., at an average cost of 70.6c. per cu.yd. Of this amount over 25,000,000 cu.yd. were removed because of slides. Of the dredging work done in Culebra Cut since water was admitted, 3,402,000 cu.yd. were removed during the year, of which 919,000 cu.yd. were earth. The average cost was 52c. per cubic yard.

The total net cost of the Panama Canal to the government of the United States, including the amount paid to the French canal company and the Republic of Panama and including the appropriation made Aug. 1, 1914, now stands at $353,559,000.

Experience with Paint on the Panama Canal Lock Gates

The enormous steel gates on the Panama Canal locks have cost the government nearly six and one-half million dollars. The lower portions of these gates are immersed in water. In the lowest locks, the water contains a large percentage of salt from the ocean. The fresh water in Gatun Lake, which flows through the locks, moreover, is heavily charged with vegetable acids from the extensive swamps submerged by the lake.

Under these conditions it was realized in advance that the protection from corrosion of the portions of the gates under water would be a very severe test of the paint applied to the gates. Moreover, those parts of the gates which are above water are exposed to much more severe conditions than exist in the climate of the temperate zone on account of the extreme heat and moisture which prevail at Panama.

Engineers interested in the preservative qualities of paints, therefore, will be much interested in the annual report of Colonel Goethals, Governor of the Canal Zone, just made public, in which the experience thus far obtained with the paints on the lock gates is summarized. We reprint this portion of the report in full as follows:

The original contract provided that the contractor should paint the gates with two coats of red lead at his expense, and with a third coat of some other pigment to be furnished by the Isthmian Canal Commission, applied to the gates at the contractor's cost. To provide for more complete protection, this agreement was modified and at Gatun arrangements were made for an additional coat, making two of red lead and two others instead of one. These additional coats consisted of one of United States Navy anticorrosive and one of antifouling paint, and were applied to those parts of the gates in the lower locks which are constantly under water. On the remaining gates at Gatun two coats of equal parts of graphite and red lead were applied.

It was intended that no red lead should be used at Pedro Miguel except for the upper guard gates, the protection to consist of three coats of damp-proof paint. At Miraflores the gates in the lower lock from elevation [illegible] to the bottom were to be given two coats of red lead, followed by one coat of anticorrosive and one coat of antifouling paint. All the other gates were to be given three coats of a proprietary paint consisting of a hydrocarbon mixture.

On account of delay in receipt of the damp-proof paints intended for use on the Pedro Miguel gates, some of these were painted with hydrocarbon paint from Miraflores and conversely a few of the Miraflores gates were painted with damp-proof paint. In all of these cases the third and fourth coats were applied by the Commission forces.

Due to impurities in the water of Gatun Lake some of the [illegible] the bitumastic which was applied directly to the metal on small portions of several of the gates of Gatun, has proved satisfactory, and the paint on those gates which are constantly under water is in very good condition.

An Unusual Type of Storm-Sewer Outlet at Passaic, N. J.

By R. F. Odell*

The unusual storm-sewer outlet here described was designed in the spring of 1914 by the writer.

In improving the street where these outlets are located, it was found necessary to make some permanent provision for caring for the storm water concentrated at this point by a 24-in. vitrified pipe sewer. This sewer had been designed several years earlier to carry the surface drainage of an area of about 40 acres of partially improved land with an average slope of 20 ft. per 1000. As there was no suitable place of discharge available at the time, an outlet into the street gutter was constructed at the point shown by Fig. 1.

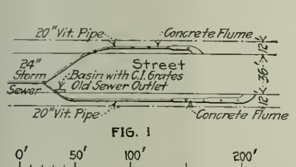

FIG. 1

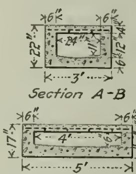

FIG. 3

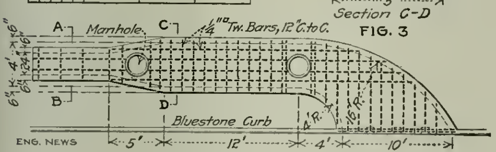

FIG. 2

This outlet was constructed in the form of a catch basin, into which the 24-in. sewer discharged. The point at which the pipe ended was about 5 ft. below the opening at the surface of the street. In times of heavy rains, the great volume of water rushed into the basin with such force as to lift the heavy cast-iron grates completely off the opening, tearing up the roadway and cobble gutters and causing considerable other damage.

When it was decided that the street be improved, including the paving of the road with asphalt-bound macadam, the advisability of constructing a relief sewer discharging into a nearby stream was discussed. It was finally decided that it would be necessary to adopt some other method, and the one here described was followed.

As shown in Fig. 1, two lines of 20-in. vitrified sewer pipe were laid from the existing manhole at the end of the 24-in. line to a point beneath the center line of the flagging on each side of the street. From these points, reinforced-concrete flumes were constructed leading to the gutters. In order to keep the grade of the flumes to the minimum allowable slope of 0.5 in 100, and to bring the two grades, of sewer and gutter, to a proper intersection, it was necessary to place the outlets at some distance from the old opening, as shown in Fig. 1.

The method of reinforcement and a plan of the flumes is shown by Fig. 2, and in Fig. 3 are shown sections at two designated points. A shallow section was necessary owing to the short distance between the run of the flume and the surface of the sidewalk. This was compensated by increasing the width as shown. It may be well to remark here that where shallow outlets or flumes of this type are constructed, it is quite necessary to place manholes or other suitable openings at close intervals to facilitate cleaning and inspection.

At the time the outlets were designed, the objection was raised that the velocity at the openings at the curb might be so great as to cause the water to rush into the street a considerable distance, and perhaps cause as much trouble as the old method. The outlets are, however, giving very satisfactory service, and have as yet shown no fault in either design or construction.

The writer personally knows of but one other flume or outlet of this type, but has heard of one or two others in this vicinity. The present city engineer, Colin R. Wise, was the first to use the idea in this section. The work was done under the writer's direction by the De Vogel Contracting Co.

*Assistant Engineer, City of Passaic, N. J.

A Novel Street-Cleaning Plan for New York City

A well conceived plan for removing snow from the streets of New York City in the winter of 1914-15 was presented to the Board of Estimate and Apportionment for approval under date of Nov. 10 by J. T. Fetherston, Commissioner of Street Cleaning.

Novel features of the plan are "snow fighting" to prevent an accumulation of snow; the largest possible use of the sewers of the city to convey the snow to the waters surrounding the city; and an emergency force of 15,000 men per shift of eight hours. Besides removal through the sewers, cart haulage by contract would be employed. In some sections, instead of removal the snow would be pushed from the center of the streets by motor-driven or horse-drawn plows. Apparently the plan also contemplates the use of the sewer to carry away snow removed by the street-railway companies from between their tracks.

An important factor would be the assignment to snow-removal work of men from other city departments, including extra clerks, inspectors, checkers, etc. The police would render aid in calling out the emergency force.

As an inducement to secure emergency men and efficient work, high rates of pay are proposed, with the choice between 30c. per hr. for regular work and 40c. per hr. for a set task accomplished within a time limit. Regular employees of the street-cleaning department working overtime would be paid regular wages for overtime, "and in addition, if the set tasks are accomplished within the time limits specified," 50% extra. To encourage men from other city departments to accept snow-work assignments, the plan provides for paying them 50% above their regular wages or salaries.

The snow schedule for 1914-15 covers a total length of 734 miles of streets and a total area of 25,830,743 sq.yd., in the boroughs of Manhattan, the Bronx and Brooklyn. Of these totals, it is proposed to use the "snow-fighting" force (to keep the snow from accumulating) on 542 miles, or 19,106,437 sq.yd.; the "snow-removal" or "contract schedule" on 94 miles, or 3,304,009 sq.yd.; and the "street-railway schedule" on 97 miles, or 3,420,297 sq.yd.

An analysis of the snowfall records for the years 1905-11, inclusive, shows the following:

	Maximum	Average
Number of storms per winter	7	4
Duration of single storm, hr.	33	13.5
Rate of fall per hour per storm, in.	0.9	0.5
Depth of snow per winter, in.	42	21.3

Conclusions Drawn from Official Test of the San Francisco Refuse Incinerator

A note to the effect that M. M. O'Shaughnessy, City Engineer of San Francisco, had recommended the rejection of the Islais Creek refuse incinerator after a test to determine whether it fulfilled the contract requirements, appeared on p. 1041 of our issue of Nov. 19. The conclusions on which this recommendation was based, as summarized by Mr. O'Shaughnessy in his official report, are printed below.

Although our note of Nov. 19 stated that the cost of incineration was in excess of the contract guarantee, the last paragraph of the quotation from Mr. O'Shaughnessy's report, given below, states that the cost guarantee "is fully met." It appears from the report that the actual cost of operating the incinerator was $1.33 per ton, as stated in our note of Nov. 19, but that after allowing for (1) steam produced, (2) excessive labor cost due to lack of refuse to operate the furnaces 22 out of 24 hours, and (3) the amount paid the city by scavengers for refuse delivered to the furnace, the contractor's guarantee of [illegible] per ton of profit is considerably exceeded.

Mr. O'Shaughnessy's summary of conclusions drawn from the tests of the incinerator is as follows:

The plant does not meet the first guarantee that no nuisance is created in its normal operation.

The plant does not meet the second guarantee that no [illegible] gases, smoke or dust escape from the [illegible] or the chimney.

The plant does not meet the third guarantee in the requirement that the temperature in the combustion chambers shall at no time fall below [illegible]° F. It does meet this guarantee in that the average temperature maintained in the combustion chambers is in excess of [illegible]° F.

The plant does not fully meet the fourth guarantee that the residue from the furnaces shall be thoroughly burned [illegible] and free from organic matter.

The plant fully meets the fifth guarantee that the furnaces, [illegible], furnaces and combustion chambers shall be so arranged that it shall not be necessary to shut down any one unit for more than [illegible] hr. in any one week in order to [illegible] clinkers, dust and ashes.

The sixth guarantee that the pounds of refuse per hour [illegible] will be incinerated per square foot of grate area shall not be less than stated in the contractor's bid is fully met.

The seventh guarantee that the average cost per ton at such plant for incinerating refuse shall not be greater than stated in the contractor's bid is fully met."

In his letter transmitting the report from which the foregoing conclusions are taken, Mr. O'Shaughnessy recommended the rejection of the incinerator, under a contract provision to the effect that if the plant did not fulfill all the contract guarantees the city might refuse to accept the plant, in which case the contractor should return to the city within 30 days all money paid to him by the city on account.

On Monday, Nov. 23, a protest against this recommendation was lodged with the Board of Public Works by the contractor, the [illegible] Co., of New York City.

[illegible]

Ohio State Highway Contracts [illegible]

[illegible]

NEWS NOTES

A Severe Freight Wreck at Harward's Station, Me., which officials of the Maine Central R.R. claim to be the worst in the history of the road, occurred on Nov. 17. Of the 50 cars in a westbound train, 31 were piled up when a car wheel broke.

A Steamship Collision in New York Bay occurred when the 26,000-ton outward-bound White Star steamship "Baltic" passed too closely on the port side of the 3000-ton "Comal," of the Mallory Line, bound for Galveston, Tex., on the afternoon of Nov. 18. The "Baltic" had drawn up abeam of the smaller vessel and was leaving her astern, when the "Comal" swerved in, her bow raking along the side of the "Baltic," due to the suction caused by the passage of the big steamer. Although she was not leaking, the bow plates and a deck beam of the "Comal" had buckled. The "Comal" returned to her pier and arrangements were made for sending her 60 passengers to Galveston by train. The "Baltic" was uninjured and continued her voyage.

Two Water Mains Were Broken in Greater New York, one in Varick St., Manhattan, that flooded the new Seventh Ave. subway excavation, and the other in Brooklyn, as the result of a heavy rainfall on Nov. 1[illegible]. At Varick and Canal St. a 20-in. main which had been undermined broke, causing a 12-in. high-pressure pipe to give way. The foundation of a 10-ft. sewer on Canal St. was scoured, cracking the piping and permitting the water inside the sewer to issue into the excavation at the Canal St. end, to a depth of 20 ft. The water in that district was turned off as soon as possible and the high-pressure main repaired. Three hours after the break, the 20-in. main had been repaired. Cobblestones were then dumped into the excavation to form a foundation for the replaced sewer, and a temporary connection made to stop the flow into the excavation. The break in Brooklyn was in a 36-in. water main on Bushwick Ave. Sidewalks were ripped up and holes torn in the street, cellars were flooded, and the water stood at street intersections in some places 3 ft. deep. The rush of water from a sewer main through a temporary wood flume in the excavation of the Flatbush Ave. and Eastern Parkway subway, Brooklyn, tore out the sides of the flume, on the same night, and for more than three hours water poured into the excavation, which was filled to a depth of 8 ft.

The East Approach to the Municipal Bridge across the Mississippi River at St. Louis is at last to be built. On Nov. 3 a bond issue of $2,750,000 was authorized by vote of the citizens of St. Louis; this bond issue had been defeated at the three previous elections. For two years the rest of the bridge has been completed, awaiting the east approach. The new construction will consist of a steel trestle, including a combined railway and highway approach [illegible] ft. in length, a railway approach [illegible] ft., and a highway approach [illegible] ft. in length. Plans are in preparation and work will probably start within the next 90 days. No contracts have been prepared to date.

Exhibition of Street Cleaning Machinery and Apparatus—A very interesting and instructive exhibit of apparatus for cleaning streets is being held at the Armory of the First Battalion of Field Artillery, [illegible] St. and Broadway, New York City, during the present week. About [illegible] manufacturers are exhibiting the most recent types of [illegible] street cleaning machinery, covering all kinds of apparatus from [illegible] to the largest automobile trucks and [illegible] street flushers. On Monday, Nov. [illegible], there was a street parade of exhibits and of the city's street cleaning forces. Each day of the exhibition there are band concerts, [illegible] pictures and lectures. The exhibition is being held under the auspices of the New York City Department of Street Cleaning, of which John T. Fetherston is chief.

The Panama Canal Construction has received the [illegible] [illegible] Canal [illegible] [illegible] West Indies, and [illegible] Central America. [illegible]

now out of work. The total number of European laborers employed by the Panama Canal and the Panama R.R. at present is about 1200.

The Cleveland Lake-Front Case has been decided in favor of the city and against the railway companies, after 21 years of litigation. The decision, which was rendered by the United States Supreme Court, on Nov. 16, gives the city possession of 30 acres of land claimed by the Cleveland & Pittsburgh, the Pennsylvania, the Cleveland, Cincinnati, Chicago & St. Louis, and the Lake Shore and Michigan Southern railways. The railways claimed title to the land under a 99-year lease made in 1849, granting the right to lay tracks on what is now West Ninth St., for which right the city was paid $100,000. Subsequently, the city filled in the lake to the north of West Ninth St. The railways claimed the filled land, but the United States Supreme Court holds that the city has title to all improvements made since 1897. The city now has possession of the lake front from West Ninth St. to the mouth of the Cuyahoga River, with the exception of that part lying between West Ninth St. and West Third St.

Bridge Reconstruction, Kansas City—The Mercantile Club, of Kansas City, Kan., held a meeting on Nov. 10, to determine the consensus of opinions of different bodies and associations who are interested in the reconstruction of the Central Ave. bridge across the Kaw River. This bridge is a double-deck structure carrying the Metropolitan cars overhead and a traffic way underneath. Owing to the fact that the bridge does not comply with the requirements of the drainage Board as to length, height above levees, etc., it has been ordered reconstructed by Judge Smith. The Metropolitan engineers have made an estimate of $115,000 on cantilever type, using the present two piers by extending them down below possible scour line. County Engineer L. R. McAlpin has made an estimate of $300,000 on the same type of bridge as is there at present. This would require two new piers and three new spans. The real-estate men and residents adjacent to Central Ave. have formed an association and are demanding a high line bridge which, it is estimated, will cost $450,000. No action has as yet been taken in this mater.

The First Brick Road in Montgomery County, Ohio, was recently completed, as a part of a projected outlay of $180,000 to be expended on similar roads radiating from Dayton, the county seat. The road is one of four radiating main market and intercounty highways. The first, the Covington road improvement, is little more than a mile in length. Two and a half miles of paving is under way on the Dayton-Cincinnati route, a trifle less on the Dayton-Troy road (a part of the through route to Toledo), and one mile on the Dayton-Greenville road. An additional mile and a half of the last named road will be graded this year in preparation for a brick surface next year. This year's program entails the expenditure of about $180,000 owing to difficult grades which have been reduced and the generally substantial scale of the undertaking. Of this, the state is furnishing one-half, a recognition of the extent of the through traffic which is destined to use these main market intercounty roads. The remaining 50% of cost is divided so that 25% falls on the county, 15% on the various townships and 10% upon the owners of adjacent land. The work has been done under the joint direction of Division Engineer Harwood Lersch, of the State Highway Department, and Victor C. Smith, surveyor of Montgomery County.

Opposition of Organized Labor to efficiency systems of shop management was voiced at the Convention of the American Federation of Labor in Philadelphia, Nov. 16. The convention adopted a resolution urging the Executive Council to continue its efforts to have abolished so called efficiency systems by which workmen are speeded up. Another resolution adopted urged that effort be made to have the federal eight-hour law made to apply to the manufacture of all materials used in government work. The ruling of the Attorney-General has been that the eight-hour law does not apply to the manufacture of materials which the government may purchase for its own use. The Federation will attempt to secure a contrary decision from Attorney-General Gregory, and if this is unavailing an effort will be made to amend the law. The Federation further went on record in regard to workmen's compensation laws with the demand that at least 66⅔% of wages should be the rate paid to relatives of workmen killed during their employment. The compensation should be paid to the widow during her widowhood and to children under eighteen years of age. The convention further favored the prohibition of employer's liability insurance companies and also permission to employers to carry their own insurance, thus making state insurance compulsory. To prevent discrimination against married men by employers engaging help, the convention voted to recommend that where a workman who is killed has no wife or other dependent, the compensation should be paid to the state.

Railway Valuation in the United States will cost about $12,500,000 to complete, according to a statement by Judge Chas. A. Prouty, Director of Physical Valuation, at the annual convention of the National Association of Railway Commissioners on Nov. 19. The valuation of the telegraph lines will cost $1,000,000 to $1,250,000 more. Regarding the probable use of the valuation when made in fixing rates and its possible use as the basis of government purchase, Judge Prouty said:

This valuation is national, but is to be made along State lines. When completed, it undoubtedly will supersede all state valuations that have been made. It will be the basis for the making not only of interstate, but of state freight rates.

Probably the most important practical question before this country today is its treatment of our railroads. Is the Government to take over these agencies of transportation, or shall they be left to the operation of private capital? Assuming that we are to leave the discharge of this function to private enterprise, what rates shall be accorded in order that the present investment may be fairly dealt with and that such further investment will be induced as will render possible the proper development of these facilities?

In the past this question has not been acute, for rates have been sufficient to maintain railroad credit, but it is evident that the time is close at hand, if it is not already here, when there is grave doubt as to whether these rates must not be generally increased. This question cannot be satisfactorily answered until there is a national valuation of these properties.

Consider the enormous amounts involved. An error of 6 or 7% in the valuation means nearly or quite a billion dollars. The interest at 6% on that sum is $60,000,000. Whether this valuation is to be used as the basis of rates to be allowed these carriers and paid by the body of our people, or whether, perchance, it may become the measure of the price to be paid by the Government for this property, that error would mean either to the railroads or to the people every year three or four times the cost of the entire valuation.

PERSONALS

Mr. Floyd F. Woods has been appointed Sales Manager of the Epping-Carpenter Pump Co., Pittsburgh, Penn., succeeding Mr. R. Bowen, resigned.

Mr. George W. Hunt, formerly President and General Manager of the Canadian Asphalt Co., Ltd., has been appointed Sales Manager for John Baker, Jr., dealer in asphalt, bituminous products and road oils, 10 South La Salle St., Chicago, Ill.

Mr. Thomas E. Mitten has been elected President of the Philadelphia Rapid Transit Co., succeeding the late Charles O. Kruger. Mr. Mitten has been Chairman of the Executive Committee since 1911. He was formerly President of the Chicago City Ry.

General Hartwig von Beseler, the German commander who besieged and captured Antwerp, has been awarded the degree of Doctor of Engineering by unanimous vote of the faculty of mechanical engineering of the Technical High School of Hannover.

Mr. H. C. Hequembourg has resigned as General Purchasing Agent of the American Locomotive Co., New York City. Until further notice the purchasing and storekeeping departments will be under the jurisdiction of Mr. Leigh Best, Vice-President.

Mr. Edward M. Bigelow, M. Am. Soc. C. E., State Highway Commissioner of Pennsylvania, who was recently indicted by the authorities of several Schuylkill County townships for alleged criminal negligence in not caring for certain roads, has won his case and the indictment has been quashed. The court held that evidence showed the State Highway Commissioner had done his best in apportioning state funds to the townships, and that his action was in no way criminal.

Col. H. G. Prout, M. Am. Soc. C. E., former President of the Union Switch & Signal Co., New York City, has been elected President of the Hall Switch & Signal Co., with headquarters in New York City. Mr. Wm. P. Hall is now Vice-President and Chairman of the Executive Committee. Col. Prout was associated with the Union Switch & Signal Co. as Vice-President and General Manager for several years, and was elected President to succeed the late George Westinghouse.

Mr. Charles W. Mullen, a graduate in civil engineering of the University of Maine, class of 1883, and for several years actively engaged in engineering construction work, has been nominated a member of the Maine State Public Utilities Commission, in place of Samuel W. Gould, of Skowhegan, whose nomination the legislature refused to confirm. The Bangor "Daily News" states that the opposition to Mr. Gould was based largely upon the widespread belief that the board should not be composed entirely of lawyers. Mr. Mullen has been twice Mayor of Bangor, and is a prominent business man of that city.

Mr [illegible] M. Am. Soc. C. E., has resigned as Chief Engineer of the [illegible] Bridge Co., Montreal, Que., to become [illegible] of [illegible]-of-Way of the New York Rys., succeeding Mr. [illegible] T [illegible], M. Am. Soc. C. E., whose resignation was noted in our issue of Nov. 5. Mr. [illegible] was associated with [illegible] & Porter, Engineers and Contractors, New York City, until February, 1913, when he went to Montreal. From 18[illegible] to 19[illegible]2 he was Chief Engineer of the Manhattan and [illegible]borough Bridges, New York City, and from 19[illegible] to 19[illegible] was Consulting Engineer in charge of [illegible] bridges.

Mr. [illegible] F. Wilcox has recently been appointed Deputy Commissioner of the Department of Water Supply, Gas and Electricity, New York City. Mr. Wilcox was formerly Chief of the Bureau of Franchises of the Public Service Commission for the First District, New York, but since July 1, 1913, has been engaged in private practice as a consulting franchise and public-utility expert. Last summer he was employed to take charge of the valuation of the private water companies operating in New York City, such companies being subject to regulation as to rates and services by the Commissioner of the Water Department. In addition to the regular duties of his new office Mr. Wilcox will carry forward to completion this valuation work.

Mr. J. G. Sing, M. Can. Soc. C. E., has resigned as District Engineer, Canadian Public Works Department, Toronto, Ont., to engage in private practice as a Consulting Engineer. He will also continue to be Consulting Engineer of the Toronto Harbor Commission. Mr. J. M. Wilson, Assoc. M. Can. Soc. C. E., Assistant Engineer, is Acting District Engineer. It is reported that Mr. C. H. M[illegible]newson, Assoc. M. Can. Soc. C. E., present Resident Engineer on the Canadian Government work for the improvement of Toronto harbor, will temporarily assume charge of the Government's share in the work, which involves an outlay of $7,[illegible]0. Mr. Sing has been District Engineer for the past ten years and as such has had charge of harbor work in eastern and northern Ontario, including practically all the waterfront on the Great Lakes.

OBITUARY

C. W. Cooper, a levee contractor of Lake Providence, La., was crushed to death in an automobile accident at Waterproof, La., Nov. 6.

[illegible] Freeman Day, former Vice-President and Manager of the Minneapolis & St. Louis R.R. and the Iowa Central Ry., died Nov. 15. He was 66 years old.

W. W. Cain, a bridge contractor for the Chicago, Rock Island & Pacific Ry., was struck and killed by a train at [illegible], Colo., Nov. 2. He was a resident of Denver, Colo., and widely known as a [illegible] owner.

James L. [illegible], a [illegible] civil engineer of Vancouver, B. C., was killed recently on a hunting trip in British Columbia. He was 28 years old, a native of Denver, Colo., and a civil engineering graduate of the University of Denver.

SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS.
Dec. 10-11. Annual meeting at New York City. Secy., D. H. Cox, 29 W. 39th St., New York City.

AMERICAN ROAD BUILDERS' ASSOCIATION.
Dec. 14-18. Convention at Chicago, Ill. Secy., E. L. Powers, 150 Nassau St., New York City.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.
Dec. 28-30. Annual meeting at Chicago, Ill. Secy., F. M. White, Madison, Wis.

American Iron and Steel Institute—At the annual convention, recently held in Birmingham, Ala., it was decided to hold the 1915 meeting at Youngstown, Ohio.

Washington (D. C.) Society of Engineers—The annual dinner of the Society was held on Nov. 19. The attendance was about 250. The Secretary is John C. Hoyt, 1330 F St. Northwest.

New York Section of American Water Works Association—The third meeting will be held at the Manhattan Hotel, New York City, on Dec. 3, at 12:30 p.m., when lunch will be served.

Northwestern Road Congress—The officers elected at the annual meeting at Milwaukee, Wis., were: President, George W. Cooley, State Highway Engineer, St. Paul, Minn.; Vice-Presidents, John Hazlewood, Madison, Wis., F. C. M[illegible], Springfield, Ill., and Otto Albertus, [illegible]nd, S. D.; Secretary-Treasurer, James P. K[illegible]enan, Milwaukee, Wis. A report of the meeting was given in our issue of Nov. 5.

Cleveland Chapter of the American Institute of Architects—At the November meeting of the Chapter, in the Hotel [illegible], Cleveland, it was resolved to recommend to the [illegible] General Assembly of Ohio the passage of a law recommending the practice of architecture, with the purpose of [illegible] the profession upon the same [illegible] as the professions of law and medicine; in general, the law to admit men to the practice of architecture by examination and to confer upon them the right to use the title of architect.

Illinois Water Supply Association—A special meeting was held in Chicago on Nov. 11 to take steps for affiliating with the American Water Works Association, as the Illinois section of the latter. This was in accordance with a ballot vote of the association, with a large majority in favor of such affiliation. [illegible]

VOLUME 72 DECEMBER 3, 1914 NUMBER 23

The Floating Caisson for the Panama Canal Locks

By Lewis A. Mason*

A huge floating caisson or gate for the Panama Canal locks was recently towed from San Francisco to the canal. Its object is to close the entrance to any of the lock chambers when the miter gates are to be painted or repaired, or when the culvert gates are to be inspected.

This caisson, designed by the writer, is believed to be the largest one ever constructed. It cost $335,000 and was over a year in building; the Union Iron Works, San Francisco, constructed it. Towing the caisson to Panama was a considerable undertaking in itself, requiring 43 days. Launching took place on July 25, 1914, and the trip to Panama started Sept. 16.

The clear width of the lock chambers is 110 ft. Beyond the line of the emergency dams the approach is widened by an offset of 3 ft. on either side. The shoulders so formed, with the connecting horizontal sill across the bottom of the chamber, will serve as a seat for the caisson. When the caisson has been floated to place in the recess, water is let into its lower compartments, causing it to sink until properly seated. After this is accomplished, pumps in the caisson unwater the lock chamber, while the water pressure from the outer side of the caisson will force it securely against its seat in the masonry. When it is desired to remove the caisson the lock chamber is filled with water by opening the culverts within the lock walls; this relieves the pressure against the outer side and the water within the caisson is then pumped out to allow it to be floated away.

The caisson is designed for use at all of the 12 lock entrances, and the entrance to the permanent dry dock at Balboa, which also has mitering gates of the same type as the locks. It has a light draft of 32 ft. to allow its convenient handling through the various locks. The top of the sill at the Pacific end of the Miraflores locks is 50 ft. below mean sea level; the tidal fluctuation, which raises the level of the water as high as 11 ft. above mean tide, requires that the caisson be sunk to a draft of 61 ft. when used at high tide. Provision for a proper freeboard makes the aggregate depth of the structure 66 ft. The achievement of statical stability at the various depths of immersion without undue bulkiness or excessive weight in the different drafts makes the caisson of especial interest.

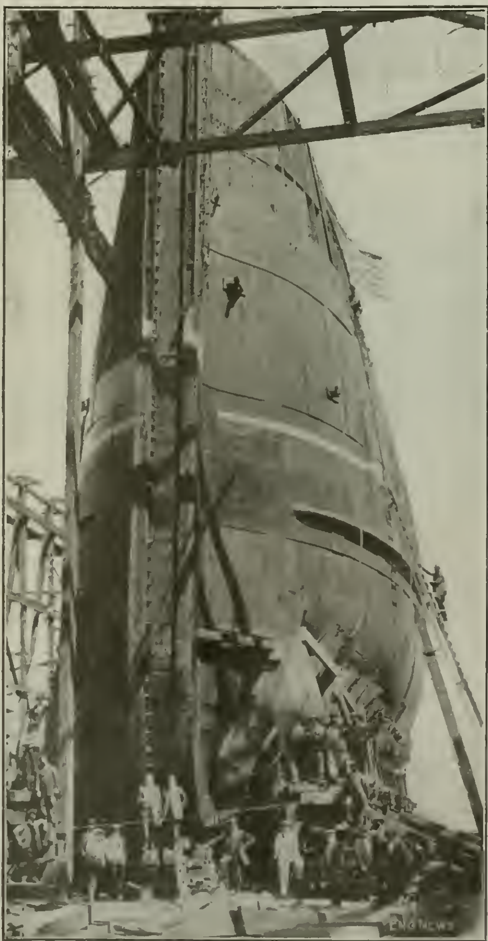

Fig. 1. Bow View of the Gate Caisson for the Panama Canal Locks on Launching Day (July 25, 1914)

(Union Iron Works, San Francisco, Calif., builders.)

In form the caisson has convex bottom, pointed ends, and sides sloped inward from the maximum width of 36 ft. (at about one-third the way up from the keel) to a breadth half as great at the top deck (see cross-section, Fig. 2). The water-line sections resemble those of merchant ships, but are more blunt at the ends on account of the vertical end girders or stems. The length is 112 ft. 6 in. between perpendiculars, and 113 ft. 10 in. over all, including the timber cushions.

Structural Design

The water pressure against the caisson (when

*Assistant Designing Engineer in office of Engineer of Maintenance of the Panama Canal, Culebra, C. Z.

acting at point is transferred to the gate recess by horizontal decks and breasthooks (short decks between the main decks at the ends). A system of vertical framing built intercostally, extending from the keel to the top deck, transmits the point loading to the various decks and cross-frames.

The essential features of the structure are the transverse and longitudinal framing, with bulkheads; the horizontal plate decks, girders and stringers; the girders at the vertical ends and along the keel; the end breast-hooks, and the sheathing plates to cover the skeleton for forming the hull proper. The material of the structure is openhearth structural steel.

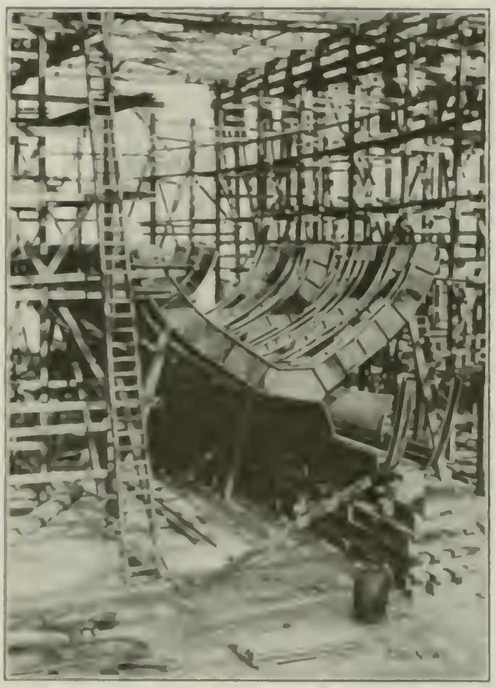

Fig. 2. Keel and Part of Lower Framing in Place (Feb. 24, 1914)

Nine cross-frames spaced 12 ft. apart, extend the entire length of the caisson; intermediate frames are spaced 2 ft. apart between the main cross-frames. All are built intercostally between the five horizontal decks. The last cross-frame at each end is made water-tight, to form peak trimming tanks for maintaining a level keel. The seven other cross-frames serve as swash bulkheads for controlling the water within the caisson.

The five horizontal decks are located, respectively, 16 ft., 25 ft., 37 ft., 49 ft., and 65 ft. above the center line of the keel plate. The 16-ft. deck forms the bottom of the trimming tank. The 37-ft. or operating deck is made absolutely water-tight; it has water-tight manholes for gaining access to the various compartments below and water-tight hatches for the removal of the pumps or valves in case it is necessary to make any repairs, etc., to them. This deck is made of sufficient strength to withstand a hydrostatic head of 25 ft. Upon it are placed the various motors for operating the pumps, the switchboard, the water gages, chain lockers, etc. The 49-ft. deck is of open-truss construction, having diagonal bracing for the central two-thirds of its length and plating covering the ends. Six breasthooks or short decks between the main decks transmit part of the loading to the vertical end girders. In addition there are two lines of longitudinal intercostals located equidistant between the keel and the 16-ft. horizontal deck, securely riveted to the transverse frames and to the sheathing.

Steel castings at the ends of the decks and breasthooks transmit the water loads to the vertical end girders.

The sheathing is composed of longitudinal plating, worked in in-and-out strakes, making lap seams and butt joints which have double splice plates. Around all of the openings in the plate decks and in the sheathing, doubling or reinforcing plates are fitted. To protect the sheathing when manoeuvering the caisson near the lock walls, fenders are provided on the exterior of the sheathing along the 25-ft. and 49-ft. levels and vertical fenders are placed between the horizontal ones at seven of the main cross-frames. The fenders are built of bent plates, so-

Fig. 3. The Caisson Starting from San Francisco for Panama

[illegible]

curely riveted and calked to the sheathing plates; the space between is filled with "Petrolastic" cement (a by-product of crude oil; specific gravity 1.02, expansion at temperature of 110° 0.0018, melting point 150° to 200° F.).

Because of the long towing distance from its place of building, two large towing rings are fastened to the sheathing and to the 43-ft. breasthook at both ends and on each side of the caisson. As a means for towing the caisson from its mooring position to any one of the lock sites, three towing rings are riveted at the level of the 37-ft. horizontal deck on both sides of the caisson.

Along the exterior of the keel and the vertical ends, channel-shaped steel castings are securely riveted to the keel, vertical ends and sheathing. Into these, cushions of British Guiana greenheart and Australian ironbark timber are fitted and bolted. Similar cushions are fitted along the sides of the keel and along the sides of the vertical ends, to serve as a seal against the gate recess.

Equipment

There are three portable cranes located on the top deck, one at each end of the caisson and one in the center. The two end cranes, capable of raising 3000 lb. at a radius of 14 ft. by two-man power, are to be used for lifting various loads from the lock walls, as well as for handling the electric power cables. The middle crane is a little heavier in construction than the end cranes, being capable of raising or lowering a load of 3000 lb. at a radius of 25 ft. by two-man power. This crane will handle the pontoon, stowed on the top deck, when it is desired to make the suction-pump-extension attachments and is capable of lifting the top sections of either of the two skylights. A hand-operated deck capstan is provided and placed at each end of the caisson on the top deck. The capstans are for the purpose of warping the caisson into its seat and each is capable of withstanding a pull of 10,000 lb.

To increase the draft of the caisson to a sufficient depth to insure its stability at light draft, and without any water in the ballast compartments, approximately 800 tons of permanent ballast, composed of iron punchings, concrete, etc., is placed in the bottom.

An anchor chain, made of material $1\frac{9}{16}$ in. in diameter, is provided at each end for mooring the caisson when not in service, to floating buoys in the lakes. The anchor chains are raised or lowered by means of hand-operated winches located at each end of the top deck.

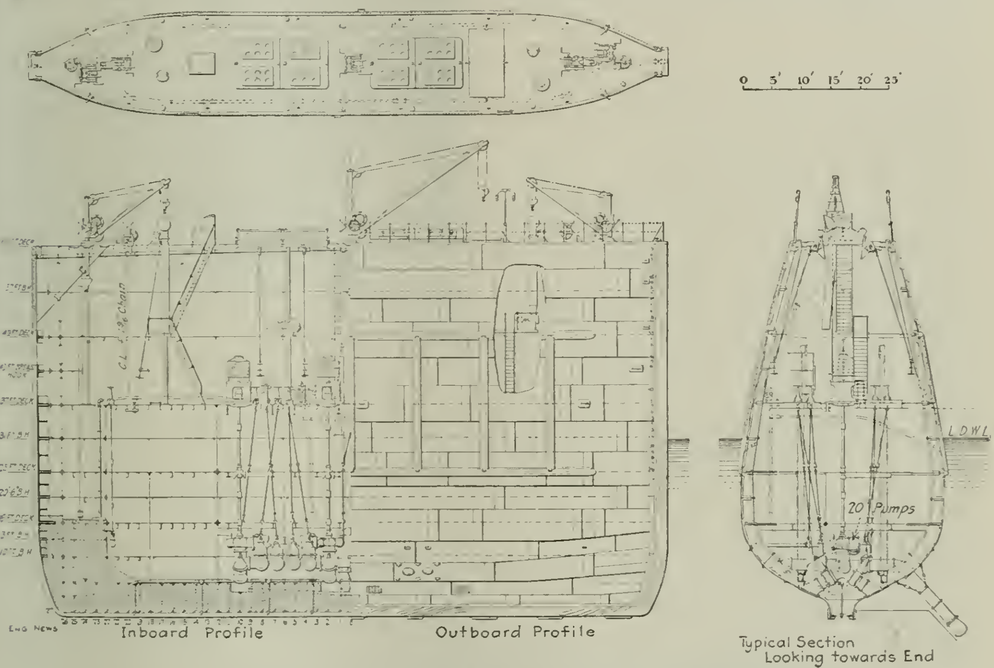

Fig. 4. General Sections, Panama Canal Gate Caisson

Pumping System

Unwatering the lock chambers (excepting the ones which may be emptied by gravity) will be done by pumps in the caisson. The only lock chambers in the canal that can be emptied by gravity are the upper lock chambers at Gatun, whose floor is $13\frac{2}{3}$ ft. above sea level.

The main pumping system consists of four vertical-shaft centrifugal pumps having a 20-in. discharge and a 22-in. suction. The capacity of the pumping system is designed so that it shall pump out in not over 25 hours' time all of the water in the upper and lower chambers of one flight of the Miraflores locks between mean sea level (El. 0) and the top of the sill of the lower chamber (El. —50), the tidal level to be at El. 0 when pumping is begun and the tide rising. The total quantity to be pumped is estimated at 10,285,000 cu.ft., including 518,000 cu.ft. for leakage through the valves in the lock culverts and around the sills of the mitering lock gates and the caisson sill. The pumps will take out, when operating at any stage of the tide, the water from the

dows of the lower lock, from the top of the sill (El. [illegible]) to 8 ft. below the sill, through a 22-in. suction pipe attached to the auxiliary suction inlets in the caisson, and discharging into the nearest lateral culvert in the lock chamber.

Two of the pumps have the piping systems arranged for pumping out the caisson when it is to be removed from its position against the sill.

When not in service, the four suction extension pipes are raised to cradles on the 50-ft. deck. They are handled by the large deck crane located at the middle of the top deck.

An electric horizontal centrifugal pump with 5½-in. suction and 4-in. discharge is located on the operating deck. It has suitable pipe connections leading from the suction to a manifold, and from the discharge to another manifold. From these manifolds piping is connected to the end peak trimming tanks, to the deck scuppers, to the sea and to a mud-sluicing device. The mud-sluicing device is intended to remove mud from the sill in an endeavor to prevent any adhesion to its seat when the caisson is in the act of raising.

The large pumps are driven by 200-hp. vertical three-phase induction motors wound for 25 cycles, 220 volts, and a speed of 750 r.p.m. The motors for operating the ventilating fan and the 3-in. auxiliary pump are induction motors of the horizontal type and with the same wiring as above. For lighting purposes 110-volt current is used. All of the electric motors with the exception of the one driving the [illegible] [illegible], and the switchboards for the same, are located on the operating deck, 47 ft. above the base line. All of the valves in the pumping system are operated from the same deck.

A New Hydraulic Stop Valve

By C. W. Larner*

The new type of hydraulic stop valve, invented by R. D. Johnson, Hydraulic Engineer of the Ontario Power Co., of Niagara Falls, N. Y., and being developed by the Wellman-Seaver-Morgan Co., for waterworks and

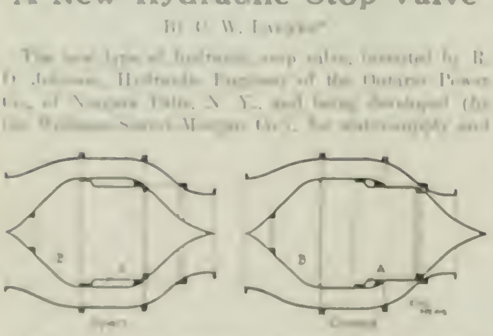

Fig. 1. Section Through a Johnson Hydraulic Valve

subsequent work is attracting widespread interest. Therefore, the following notes on design and construction are offered.

Fig. 1 shows the general arrangement of a horizontal valve of this type. It consists essentially of a circular body forming an enlargement of the pipe-line or penstock, and having an internal cylindrical chamber containing a sliding plunger. The closed end of the internal chamber and the head of the plunger are designed to guide the water smoothly as it enters and leaves the

*[illegible] Engineer, Wellman-Seaver-Morgan Co., Cleveland, Ohio.

Fig. 2. A [illegible]-Ft. Vertical Johnson Valve Built for the Ontario Power Co.

valve. The waterways throughout the valve offer no obstruction to the flow, and the loss of head is practically nothing.

When the plunger is withdrawn into the internal or operating chamber (at the left, in Fig. 1), the valve is open and presents a clear passage for the water. When the plunger is extended from the operating chamber, it seats against a ground ring in the neck of the valve body, stopping the flow. The standard control mechanism provides for only the open and closed positions of the plunger, but it may be specially arranged to hold the plunger at intermediate positions if desired.

The valve plunger is of the differential type, forming an annular chamber A within the operating chamber B. The valve is equipped with suitable vents and a control valve which admits pipe-line pressure to A and exhausts it from B to open the valve, and admits it to B and exhausts it from A to close the valve. The valve may be operated equally well in still or flowing water, and the direction of flow through the valve is immaterial. In contrast with the gate or butterfly types, it may be closed without imposing unusual stress on any part of the valve. In case of a break in the pipe-line beyond the valve, there is no difficulty in closing the latter in the usual manner and at the usual rate. There is no possibility of water-hammer.

The control valve for small valves is of the plug type and that for large valves is of the balanced-piston type. Both may be operated by hand or by electricity. All of the valves so far built have been equipped with both methods of operation. The control valve and its operating mechanism may be located at a considerable distance from the Johnson valve, if desirable. Thus, the latter can be placed outside of a power house and the control mechanism placed inside—an arrangement which may effect a large saving in the cost of a plant.

The neck of the valve body, where the plunger seats,

is made smaller than the other end which connects directly to the penstock or pipe-line. A taper section of pipe is installed between the small end of the valve and the pipe line at that end. This arrangement makes a Venturi meter out of the valve, which may be utilized for the measurement of water. Two 12-ft. valves now under construction for the Utah Power & Light Co. will have recording instruments attached to give a daily chart of the quantity of water supplied to the turbines.

Use of the Johnson design is not limited to stop valves. It may be installed for the regulation of impulse wheels in place of the usual type of needle nozzle. Then the oil or water from the governor system acts directly on the valve plunger. This is much simpler and more direct than the customary arrangement in which the plunger is mechanically operated by a regulating cylinder under governor control. Another application of this valve is for automatic pressure relief. The valve plunger is held closed by air pressure so arranged that it is automatically released and discharged when the pipe-line pressure exceeds normal by some predetermined amount. The advantage of using air pressure lies in the rapidity with which the air may be discharged, and the consequent rapid opening of the relief valve.

It is possible to arrange these valves to close automatically in case of a break in the pipe line on either side of the valve, provided the break is sufficiently bad to reduce materially the pressure at one end of the valve. This feature is of inestimable advantage for water-works service. Great damage to property has resulted in many cases from broken mains, because of the inevitable time which must elapse before the valves can be closed by hand, and the great difficulty experienced in closing gate valves under such conditions.

Periodical Levee Slip at Helena, Ark.

In our issue of Nov. 20, 1913, was given an account of the sloughing off of 1,500,000 cu.yd. of earth from one of the largest levees in the Mississippi Valley, and also some account of the history of that particular levee, which showed that sloughing off during periods of extreme low water was a regular occurrence.

Consequently it was presumed that readers would be interested in the method of reconstruction, and accordingly, in our issue of Mar. 19, 1914, a description of the rebuilding of the levee by dumping from a 20-ft. trestle was given, together with a statement by the engineer in harge defending this method, which he contended resulted in better compacting the earth than when the fill was made by teams in 3-ft. layers, in the regular way.

Be that as it may, our readers will be interested to know that during the dry season of August and September of this year, a new slip occurred in this new levee, which near the place shown in the accompanying illustrations was about 300 ft. in the rear of the old levee. This latest slip occurred at the junction of the old and new levees, or above the breaks of previous years. The estimated loss by the new slip is $20,000. It has not been possible to obtain any information about this latest slip from the engineer in charge.

VIII--Excavation

The general specifications provide for the classification of excavation as earth and rock, rock being ledge rock or place rock boulders over ½ cu. yd. Earth excavation is classified as above or below mean high water, and the prices "include the cost of the disposal of the materials excavated, of backfilling, of all decking and bridging for support of street travel, of all sheeting and bracing,

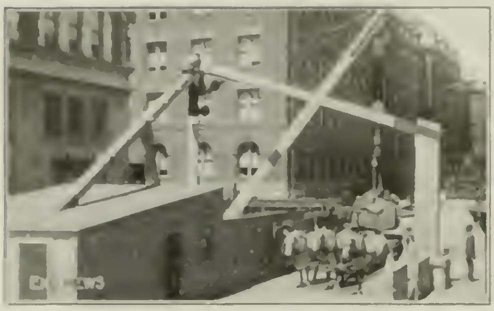

FIG. 43. DERRICK FOR HOISTING SKIPS AT 77TH ST. AND LEXINGTON AVE.

and of maintenance and supporting of [illegible] during and after excavation, of all pumping or bailing, and of the maintenance and support, with all incidental work, labor and material of any kind, of all surface, subsurface and overhead structures and surfaces." (Support of street railway [illegible] and elevated railroads is paid for separately as [illegible].) Underpinning of buildings when required is also paid for separately.

Rock excavation is paid for, for [illegible] in. outside the neat line of the [illegible] but no allowance is made on the bottom. It is required that all excavation in rock beyond the side and lines of the structure shall be refilled solid with concrete which, except for the first [illegible] in., is at the expense of the contractor, so there is every incentive to avoid excessive excavation and for the use of care in drilling and blasting at the sides.

When pipes, sewers, electric-wire conduits, etc., have to be removed and rebuilt elsewhere, the work is paid for separately. All structures of this kind, however, which do not require change have to be supported and maintained by the contractor, the cost being included in the price paid for excavation. All gas pipes are removed and placed above ground during construction and replaced afterwards, the expense being considerable of course, having to be changed each time. This work is paid for at a price bid per lineal foot for each size of pipe which has to be taken care of. The ordinary [illegible] and [illegible] in. pipes from which the house supplies are taken are usually carried along the edge of the sidewalk, on top of the [illegible] decking. The larger [illegible] and [illegible] in. mains are usually supported overhead.

In planning the excavation, it has generally been found advisable to so arrange the work that if the material is suitable, there will be sufficient left till the end to complete or nearly complete the backfill, which the specifications require shall be made with "sand, gravel or other good, clean earth, free from perishable material, or stones exceeding 6 in. in diameter, and not containing in any place a proportion of stone of or below that size exceeding one part of stone to five parts of earth."

Usually there is no opportunity to store material for this purpose, but on some sections, where there is earth, a certain portion at the ends of the section is left to be excavated after most of the structure is completed. When this is not possible, or where there is little or no earth, dependence is usually placed on material excavated elsewhere, mostly from cellars, etc., of which there is usually sufficient available at all times and in nearly all sections of New York. In one case the contractor was able to get a vacant lot for disposal of his earth excavation, conveniently located so that it will be practical to remove the material [illegible] when required and use it for backfill.

FIG. 44. GANTRY HOIST FOR SKIPS AT 121ST ST. AND LEXINGTON AVE.

The following table will give a general idea of the range of prices bid for excavation under the many varying conditions:

COST OF DIFFERENT TYPES OF EXCAVATION

*Concluded [illegible] W. [illegible].
†Consulting Engineer, [illegible] St., New York City.

The cost of supporting the tracks of the street or elevated railways is not included in the excavation price, but is paid for separately. The prices bid on the contracts thus far awarded range approximately as follows:

For the support of elevated-railway columns, from $300 to $500 each, though in one case where there were only two, the bid price was $1000 each.

For the support of main electric-railway tracks with underground trolley conduits from $5 to $20 per lin. ft. of single track. A fair average seems to be about $10.

For horse-railway tracks about $5 per lin.ft.

The excavation price does not include the relaying of the sidewalks or curb or repaving the streets, within the neat lines of the excavation; this is paid for at prices bid per square yard, for the various types of pavement. All street surfaces are first repaved with Belgian blocks and maintained by the contractor for six months, after which the final form of new pavement is laid.

Where auto-trucks are used for disposal of excavation, a storage hopper is usually provided at the head of the shaft, which will hold at least one load (or more, depending on the number of trucks in use, and the kind of material), so that there is no more delay in loading than that necessary to open the mouth of the hopper and fill the truck. The general practice seems to be to use hoppers and chutes when the excavated material is earth or a mixture of earth and boulders and to use some form of skip or bucket for rock.

On the Broadway line below 23rd St. the excavation is nearly all in earth. A small amount of rock is found in places but not enough to influence the methods. On account of the timbering and the necessary supports of the street decking, it has apparently been found most convenient and practical to handle all the material by hand. It is shoveled into buckets of about 1 yard capacity, hauled to shafts, hoisted and dumped into storage hoppers holding 25 to 50 yards, from whence it is discharged into wagons. Haulage to the water front is done almost wholly by teams, but auto-trucks are used on Section 1.

FIG. 15. TELPHER HOIST AT 74TH ST. AND LEXINGTON AVE.

The eight-hour labor law is strictly applied to all this work, no blasting is allowed between 11 p.m. and 7 a.m. and of course, all charges of explosives have to be quite light on account of danger to the timbering or adjacent buildings. On most of the work two shifts are employed, the men generally working from 6 a.m. to 2:30 p.m. and from 3 p.m. to 11:30 p.m. with half an hour for a meal.

All, or nearly all the material taken from the excavation in Manhattan has to be disposed of, usually by haulage to the water front, where it is loaded on scows and towed to the point of disposal. This involves the renting of pier or dock facilities by contractors, and a haul varying from ½ to 1 or 2 miles in wagons or auto-trucks. These latter, holding from 3 to 4 cu.yd., are being quite commonly used, and are generally said to be more satisfactory and cheaper than horse-drawn wagons. It is necessary that they be fully utilized—that is, that there be the least possible delay at loading and unloading points; otherwise the overhead charges, chauffeur's wages, and interest on investment, amount to too large a proportion of the unit cost.

A very efficient and convenient arrangement of hoist and storage hoppers, Fig. 46, was installed at Broadway and Waverly Pl., on Section 4, by the Dock Contractor Co. A vacant lot permitted the construction of a long narrow head-house parallel to the street and over the sidewalk. A telpher was arranged over the shaft and hoppers, which allowed a much more rapid, because better controlled, handling of the buckets than is possible with a derrick boom. A structure of this type would not have been permitted in front of an occupied building.

On one section on Broadway, where the excavation was mostly sand, a belt conveyor was used in the bottom which dumped the material into a hopper, from whence it was elevated to the bin above the street by an endless chain of buckets.

On these downtown sections, fewer shafts are permitted and they are usually from 1200 to 1500 ft. apart, making

Fig. 46. Headhouse over Shaft at Waverly Pl. and Broadway

the necessary maximum load on the bottom about half size. Track of 24-in. gage is generally used, two or sometimes three lines, with mules for haulage. In many places on the upper levels between timbers, small $\frac{3}{4}$-yd. cars are used, which are pushed by hand short distances to where they can be dumped to the lower level. A typical crossing over the street for handling materials is shown in Fig. 47.

Where the line crosses Union Square, most of the work masses of concrete over 20 in. in thickness, and some of it is used for rubble for blocking up the yokes of the street-railway tracks in Manhattan.

Buckets and Skips

On many parts of the work, $\frac{3}{4}$- to 1-yd. buckets as shown at A and B, Fig. 48, are used. These are handled in the excavation on small flat-cars on 24-in. gage track, hauled by mules to the shafts, hoisted by derricks to the surface and dumped into the trucks or hoppers. At the face of the cut the buckets are loaded by hand, the simple form of block and tackle being used to haul out and lift the boulders or pieces of rock too large to be conveniently handled by one or two men.

In one case where turntables were tried opposite the shaft, the tracks being arranged as shown at A, Fig. 49, it was found that they frequently got out of order and caused considerable delay, so they were taken out and the tracks arranged as shown at B, the shaft being enlarged to permit of this being done. On Sections 8 to 11 on Lexington Ave., transfer tables were used at the shafts as shown in Fig. 52.

On certain sections 3- to 4-yd. skips of the type shown in Fig. 44C are used. They are hoisted to the surface and either dumped into a wagon or auto-truck or placed on the wagon bed, and hauled to the place of disposal, where it is again lifted and then dumped. The skips are handled underground on small cars drawn by mules, or in one case where the timbering was very close and the headroom low, pushed by hand, the work being arranged so that there was a down grade to the shaft.

Fig. 47. Bridge and Decking at Grand St. and Broadway

the dirt is dumped into an electrically operated shovel being used. Shovels and trains were used on the open-cut work of the Sea Beach line in Brooklyn, and part of the Van ... was done in open cut.

The rock excavated from the subway is of little general use for structural purposes. A certain amount of the best of it is permitted to be used in ... with ...

The advantage of these large skips over the smaller buckets is greater facility in loading. They are taken off the cars and placed on the ground at the surface, a hoisting engine with a fall suspended from the timbering at the street decking being used for the purpose. There is no lift for the ... and ...

course, very much larger pieces of rock can be handled without block-holing and handled more easily.

On Sections 8, 9, 10 and 11, on Lexington Ave., a type of bucket known on the work as a "battleship" (Fig. 43) is used. These buckets hold from 1½ to 2 yards; they are handled in the excavation and tunnels of these sections on small cars (3-ft. gage) with cradles shaped to fit. The cars coast down grade either to or from the working face as the case may be, and are hauled up grade by small stationary hoisting engines. The line from the hoisting engine is usually carried out by hand and this method of haulage does not seem very efficient.

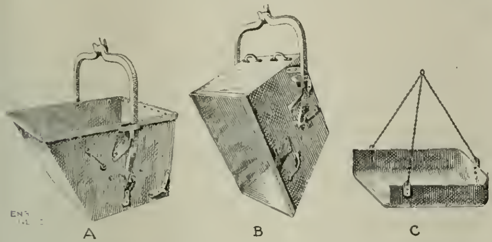

Fig. 48. Dump Buckets for Handling Material

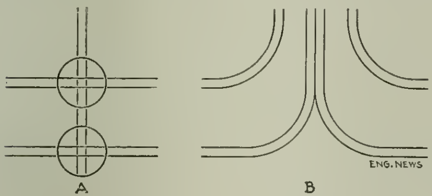

Fig. 49. Sketch of Track Arrangements at Shaft

The buckets are hoisted to the surface by derricks, Fig. 43, or telpher, Fig. 45, placed on wagon beds and hauled to the dock by horses. This type of bucket with the top some 3½ or 4 ft. above the ground (as they remain on the cars while being loaded) involves a fairly high lift for the shovelers, and the necessity of keeping the tracks up close to the face does not permit the flexibility which is possible with the skips, which are taken off the cars and placed in the most convenient position for loading. Many of these small tunnel cars consist merely of a rectangular frame of 6-in. I-beams to which the axle boxes for two axles are fastened. Those for use with the "battleships" have two or three wooden cross-pieces or cradles cut to fit.

The contracts for Sections 8, 10 and 11, Lexington Ave., are being executed by the Bradley Contracting Co., that for Section 9 by Patrick McGovern & Co. Nearly the whole length of the lower level tracks is in tunnel, the excavation of which is described separately, but the upper-level double track has generally been built as cut and cover. An arrangement has been made whereby the Bradley Company takes care of the disposal of all the material, that from the upper section being hauled to the dock at 96th St. and the East River, and from the lower sections to 76th and 68th Sts.

The use of these skips or the "battleships" is probably of greater advantage in rock excavation than in earth, as some kind of mechanical apparatus for handling the rock is generally necessary at the face and is therefore available to handle the skips on and off the cars and to load large pieces of rock. Small power shovels, operated by electricity or air, are often used for loading the spoil on underground work, but on most of the subway work, the extensive and close system of timbering hardly admits of their use.

The system used for the rock excavation on Section 13 (McMullen, Snare & Triest) seems to be quite effective. Here the rock face is 25 to 35 ft. high, and 40 to 50 ft. wide. After the street decking was put in, a top lift, from 12 to 15 ft. high and mostly earth was taken off the whole length of the section, this permitting working access to the whole job, for underpinning, support of pipes, conduits, etc. A shaft was sunk to subgrade at every other cross street, about every 450 ft., and outside the main excavation. The location of the shafts in the cross streets is shown clearly in the photographs, Figs. 44 and 45. From this shaft a cut was drifted across the full width of the work and the excavation carried forward in both directions from it. About 120 skips were used on this section, and about 400 yd. of rock (place measurement) was handled each 24 hours from the two working faces with the two gantries.

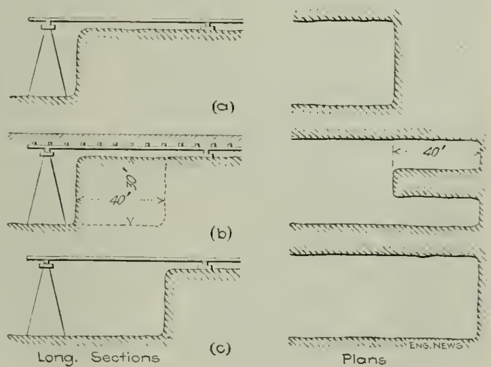

Fig. 50. Sketch Illustrating Progress of Excavation in Deep Rock Tunnel on Section 13, Lexington Ave.

The tower form of timbering (as described under timbering) was used, the working space being spanned by continuous I-beams reaching from the last towers to blocking on the floor of the first lift, as shown in the sketch, Fig. 50. Two side cuts, each about one-third the width of the excavation, were driven ahead 35 to 40 ft., then the center was blasted sideways into these cuts. This, as will be seen, protected the timbering, at least to a considerable extent, from direct blasting against it. When the face at the center was advanced 40 ft., another tower was erected, the girders moved ahead, the process repeated, etc.

Two double-drum air hoisting engines were located back from the face on top, with single fall lines leading over sheaves suspended from the timbers of the street decking above the working space. These two lines (two on each side) handled the larger pieces of rock and the skips on and off the cars, and were also used in handling timbers, etc.

Hoisting and Gantries

On Section 13, Lexington Ave. (McMullen, Snare & Triest), gantries as shown in Fig. 44, have been installed at the shafts, instead of derricks for hoisting material out of the excavation, and for lowering the structural material. The advantages of these gantries are said to be, greater safety to the public in the streets, greater rigidity, and therefore more security; better speed in hoisting, easier spilling of the skips over the wagon bed, less power required for hoisting, and the elimination of booming up and down with loads. It is said that the saving of power (in regard to which no definite data are available) is due largely to the elimination of the swinging engines which are necessary with derricks. It is also stated that there is a considerable saving in the wire hoisting ropes, which lasted only two to four weeks on the derricks, but which last three to four times as long on the gantries.

These gantries will also handle heavy loads with much greater security; those now in use have handled loads up to 25 tons. This is of considerable advantage to the rock excavation, as it permits the handling of large rocks without breaking them up. They are so arranged that from 20 to 25 loaded skips can be stored at them (see Fig. 45), thus permitting night work when the teams are not available to haul the material and also permitting considerable flexibility. This latter is a great advantage, owing to the difficulties of disposal, which is dependent on the availability of the scows, a somewhat uncertain circumstance of the winter season weather, the difficulties of haulage in bad weather, and many other factors, as already noted. The teams which haul the spoil to the dumps work only in the daytime, and by storing the material under the gantries delays are avoided and the work is accommodated to that length of time. On this work the top stone is generally loaded into the skips during the day and the finer material, which must be shoveled, is handled in the night shift.

The first of these gantries was made about 40 ft. long and 20 ft. high, and those built afterwards were made 60 ft. long and 25 ft. high, thus giving more storage room, and the extra height greater facility in handling some of the structural steel. There are altogether seven of these in use on Section 13 and one shaft with a derrick. Their use on Section 13 has been apparently very successful, but it is to be noted that they are peculiarly well adapted to the conditions there, and it cannot be assumed that they would replace derricks to so great advantage under other conditions.

Miscellaneous Excavation Methods

On the first section north of the Harlem River (Section 15, Route 5—Rodgers and Hagerty, contractors), where more latitude was allowed in the matter of opening up the streets, only part of the excavation being decked over, the excavated material was handled in 4-yd. Western dump cars hauled by dinkeys (3-ft. gage) to the disposal grounds $\frac{1}{2}$ to $\frac{3}{4}$ mile distant.

On the next section to the north at the junction of the Southern Boulevard and 138th St., a model 49 Marion shovel is just being installed for loading the cars and a model 60 Marion was used in the deep rock cut through

Fig. 51. A Rock Slide, Lexington Ave. Subway

Fig. 52. A Transfer Platform, Lexington Ave. Subway

Franz Sigel Park, on the northwest end of Section 1[illegible].

On the steep hill on Lexington Ave. between 102nd and 103rd St. where the traffic is light (on account of the steepness of the hill) and where the tunnel with all four tracks at the same level changes to a two-level section, one side of the street was left open and a cableway was installed for handling the material.

Walton St. is being widened from its original width of about 60 ft. to 100 ft. and the excavation in this widened portion is being made in open cut, the original width of the street being decked over and the material under it taken out at the open sides. The first lift of 10 to 12 ft. is loaded directly into wagons by shoveling, cribbing being built from the surface down to this depth. Much of the excavation is sand, and below the first lift this is loaded into 1-yd. V-shaped Koppel cars which are dumped sideways into a hopper, under which runs a short belt conveyor, which in turn carries the material to a bucket elevator which raises it into a storage hopper above the street level.

Steam shovels were quite generally used on the construction of the 4th Ave., Brooklyn, lines in 1909-10 and

are being used now on the open-cut work of the Sea Beach line, but generally speaking, very little use is made of mechanical apparatus of any kind on the subway excavation, most of the excavated material being shoveled by hand.

Drilling

On Section 13 the drillers work in two 8-hr. shifts, from 6 a.m. to 11 p.m., and the muckers in two shifts, from 8 p.m. to 1 a.m. One feature of considerable interest, is the quite extensive use of the so called Jap or hand hammer drill with hollow drill steel. The New York rock, a soft to medium hard gneiss or mica schist, seems to lend itself particularly well to the operation of this kind of drill in excavations where most of the holes are down holes. The type which is in most general use, is the Ingersoll-Rand B.C.R. 33, which weighs about 90 lb., using air at 80 to 90 lb. pressure. The hollow drill steel is usually about 1⅛ in. octagon, the holes are drilled dry, the air through the steel blowing out most of the dust, therefore keeping the holes clean and consequently increasing the effectiveness of the machines. These drills are used for drilling holes to depths up to 12 and 14 ft.; it is stated that they require from 50 to 75% less air at the same pressure than the usual tripod drill does, and only one man is required to operate each of them. The general opinion seems to be that unskilled laborers with very little instruction could use these drills, though, of course, in New York the labor unions compel the employment of regular union drill runners.

On Section 14 (McMullen & Hoff) four men with as many drills were averaging from 80 to 90 ft. of hole per man per day of eight hours. There was one record of 113 ft. for one man in eight hours. It was considered advisable to keep a number of spare drills on hand, so that in case anything went wrong, there was no delay, and any damaged drill could be taken to the shops, where it could be carefully repaired by a competent machinist, even though the trouble was very slight. This was considered to be better than to have an ordinary drill runner try to fix it with the spanner or sledge hammer, the tools usually used by them when anything is wrong with a drill. These drills were also used on the heavy rock excavation of Section 13, a cut 30 to 50 ft. wide and as many feet deep, with excellent results.

On some sections a lighter type of drill weighing about 40 lb. and using about 50 ft. of air per min. is being used; this is the Ingersoll-Rand B.R.C. No. 430 or so called Jackhamer type, used for holes up to 6 and 8 ft. in depth using ⅞-in. hollow steel.

Another point of interest is the almost universal use of machine drill sharpeners, nearly all of which are of the Leyner type. This use of machine sharpeners is possibly due, to some extent, to the use of the hollow steel and the rose-shape form of bit generally used with these hand drills, though of course, it has been shown even with the old type of cross bit, that where the number of drills warranted, the installation of a drill sharpener was an economy.

It was noted that in many cases the heads of the steel drills had sheared square off just back of the head. This type of failure has not previously come to the writer's notice, and no adequate explanation was offered by the men on the work, but it would seem that it might be due to the severe internal stresses set up by the much greater force used in the machine sharpeners in forming the heads, and the fact that possibly in these machine sharpeners, the steel can be, and is, worked at a lower temperature than by hand.

It is stated by the contractors on Sec. 13 and 14 that the general breakage and wastage of steel used is rather greater than with the ordinary steel, and, of course, the hollow steel is more expensive, but it is thought this is much more than compensated by the greater amount of work done. The Leyner drill sharpeners are used to make all the bolts for the timbering on one section, where it was stated that 400 bolts were headed per hour.

Electric current is used for power at most of the compressor plants, and air is usually piped to all points of the work for use in drills, pneumatic riveters, etc. In some cases the air is used for operating hoists and derricks, in other cases electric power is used directly for this purpose; this apparently is governed most generally by the plant the contractor may have had on hand, but the use of air for hoists and derricks, so long as it has to be installed in any event, seems to be the most satisfactory and most generally used.

Various schemes for heating the air during cold weather were noted, some of the apparatus home-made and other manufactured especially for the purpose. On one section (McMullen, Snare & Triest) an upright coil of about 6 to 8 rings, 15 to 18 inches in diameter, was made in the air line near the point where it was to be used, and a fire built and maintained inside the coil. In another case a piece of 6- or 8-in. pipe about 3 ft. long was capped at the ends to take the regular air line (about 2 in.) and a fire built under the larger section. These home-made schemes are probably somewhat wasteful of fuel, but this amounts to very little and they probably stand up better under the rough usage they get on this kind of work than the manufactured heaters.

An Efficient Method of Resuscitation has been developed by a committee of eminent physicians and surgeons appointed by the U. S. Bureau of Mines. As a result of a report made by this committee, J. A. Holmes, Director of the Bureau, has recommended first-aid procedure which has the recommendation of successful experience.

The recommendations are of universal application, not only to men who are overcome by electric shock or gases in mines, but also to persons suffering from the effects of illuminating-gas poisoning or from electric shock anywhere.

An abstract of the recommendations follows:

In case of gas poisoning, remove the victim at once from the gaseous atmosphere. Carry him quickly to fresh air and immediately give manual artificial respiration. Do not stop to loosen clothing. Every moment of delay is serious.

In case of electric shock, break electric current instantly. Free the patient from the current with a single quick motion, using any dry non-conductor, such as clothing, rope, or board, to move patient or wire. Beware of using any metal or moist material. Meantime have every effort made to shut off current.

Attend instantly to the victim's breathing. If the victim is not breathing, he should be given manual artificial respiration at once. If the patient is breathing slowly and regularly, do not give artificial respiration, but let nature restore breathing unaided. In gas cases, give oxygen. If the patient has been a victim of gas, give him pure oxygen, with manual artificial respiration. The oxygen may be given through a breathing bag from a cylinder having a reducing valve, with connecting tubes and face mask, and with an inspiratory and an expiratory valve, of which the latter communicates directly with the atmosphere.

No mechanical artificial resuscitating device should be used unless one operated by hand that has no suction effect on the lungs. Use the Schaefer or prone-pressure method of artificial respiration. Begin at once. A moment's delay is serious. Continue the artificial respiration. If necessary, continue two hours or longer without interruption until natural breathing is restored. If natural breathing stops after being restored, use artificial respiration again.

Do not give the patient any liquid, until he is fully conscious. Give him fresh air, but keep his body warm.

Send for the nearest doctor as soon as accident is discovered.

A Small Slow Sand Water-Filter Plant for the Estate of J. P. Morgan

By John H. [illegible]*

The domestic water-supply for Cragston, the estate of J. Pierpont Morgan, at Highland Falls, N. Y., is ordinarily obtained by gravity through a 2-in. pipe from a spring situated on high ground about one mile distant from the main house. For the greenhouses, sprinkling and other miscellaneous purposes, water is obtained, also by gravity, through a 4-in. pipe from an artificial pond, located about

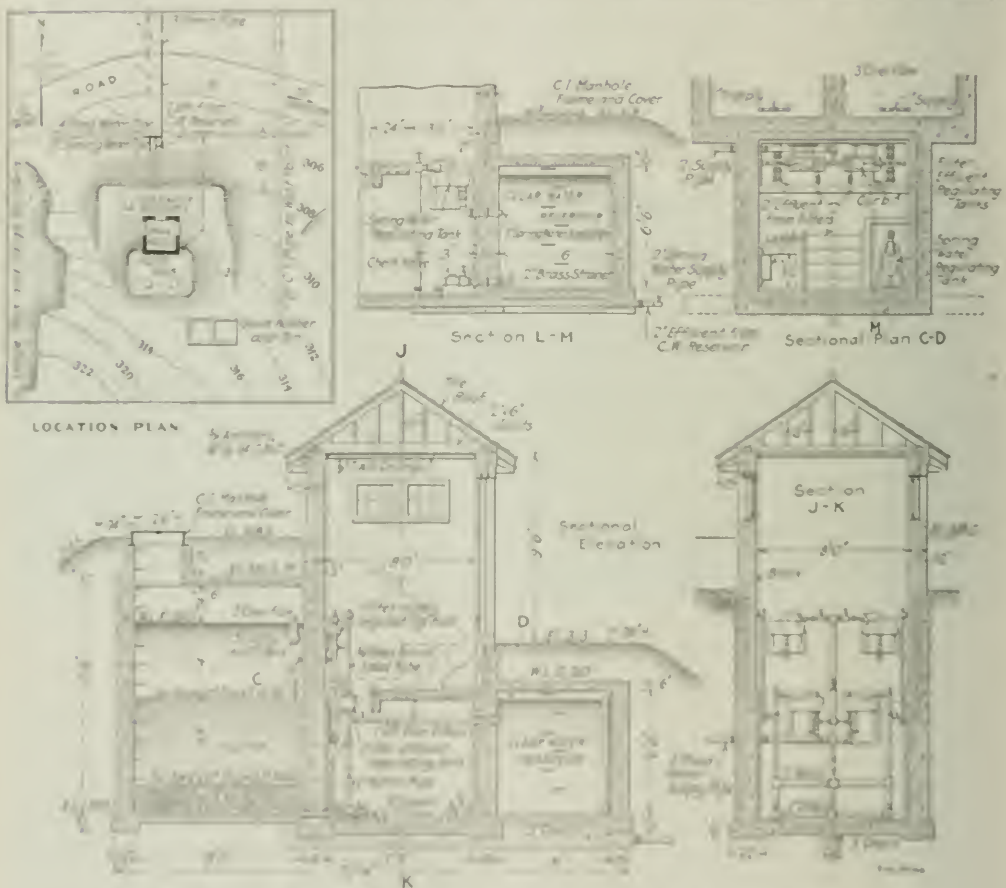

FIG. 1. SLOW SAND WATER-FILTER PLANT FOR THE ESTATE OF J. P. MORGAN

[illegible] ft. from and about 170 ft. above the main house. The water has usually been adequate and sufficient water for all the [illegible], but during a severe drought the spring failed to supply sufficient water and in order to meet the deficiency, as well as to provide a reserve supply of domestic water, a small filter plant was built to filter water obtained from the pond.

The filter plant, which has a capacity of 5000 gal. per 24 hours, consists of two small covered slow sand filters, a regulating house and a clear water reservoir, and is located about 100 ft. in elevation above the main house and at a point where the 2-in. spring-water pipe and the 4-in. pond-water pipe are in close proximity, so that use could be made of both without laying any additional pipe lines. A general plan and details of the plant are shown in Fig. 1.

The filters, which are each 6 ft. wide by 9 ft. long, have a total filtering area of 108 sq.ft. and are designed to operate at a rate of 2,000,000 gal. per acre per 24 hours. The filter sand was purchased from the city of Albany, from the surplus stock of sand on hand at the slow sand filter plant there, and has a total depth of $3\frac{1}{2}$ ft. above the filter gravel. The sand has an effective size of 0.31 mm. and a uniformity coefficient of 3.25, with sizes from 0.17 mm. The depth of water above the sand is 4 ft.

The filter gravel has a total depth of 18 in., placed in four layers as follows:

Size	Thickness, in.
Coarser than filter sand	[illegible]
[illegible] in.	[illegible]
[illegible] in.	[illegible]
[illegible] in.	[illegible]

*[illegible] Engineers and Sanitary Experts, [illegible]

The regulating chamber, which is placed between the filters and the clear-water reservoir, is 7 ft. 8 in. square and contains all the piping and apparatus for operating the filters. The chamber is surmounted by a small superstructure built of brick (Fig. 2).

The clear-water reservoir is 6 ft. wide, 20 ft. long and 6½ ft. deep, and with a water depth of 6 ft. contains about 5100 gal., or a little over one day's supply.

Water for the filter plant is drawn from the 4-in. pond-water pipe through a 2-in. pipe connecting with two filter-supply regulating tanks, from which in turn it passes into the filters. These regulating tanks are each fitted with a balanced float valve to maintain a constant water level on the filters and to prevent overflow, as the filters are located at a point about 55 ft. below the level of the pond.

The effluent from each filter passes through a filter-effluent regulating tank, in which a constant level is maintained by means of a ball cock, the rate of filtration being controlled by an adjustable brass orifice placed in the bottom of the tank. From these tanks the filtered water passes to the clear-water reservoir.

Fig. 2. Regulating House of Slow Sand Filter Plant

The piping connections to and from the plant are so arranged that the plant can be run in connection with or independently of the spring-water supply and also so that the clear-water reservoir can be used to store spring water when the spring-water supply is sufficient. When running independently the spring-water supply will be entirely cut off. When the spring-water supply is sufficient and the clear-water reservoir is used to store spring water, the filters will be cut off. When used in connection with the spring-water supply, all of the spring water will pass through the clear-water reservoir and the deficiency in spring water will be made up by the filters.

Under this last method of operation, the spring water will pass to the clear-water reservoir through a spring-water regulating tank, fitted with a balanced valve to prevent overflow of the clear-water reservoir. As the draft exceeds the supply of spring water, the water level in the clear-water reservoir will drop and the filters will start up slowly until the maximum rate of filtration is reached. Conversely, as the draft decreases and the clear-water reservoir fills up, the filters will gradually slow down and finally cease filtering when the clear-water reservoir is full.

The filters were designed and built under the direction of Hering & Gregory, Consulting Engineers, of New York, with J. K. Giesey and I. S. Walker as Resident Engineers. The construction work was carried out by Westinghouse, Church, Kerr & Co., of New York, with Howard S. Barton in charge.

Alloy-Steel Rails

Extensive experiments with the use of special alloy steels for rails have been made during the past few years. But the report presented at the recent annual convention of the American Electric Railway Association by the Committee on Way, states that the production of such rails has decreased materially during the past few years and is now insignificant in relation to the total rail production. The figures are given in Table I:

TABLE I—PRODUCTION OF RAILS OF VARIOUS ALLOY STEELS (GROSS TONS)

	Openhearth and Electric	Bessemer	Total
1909	13,696	35,699	49,395
1910	27,389	229,935	257,324
1911	38,539	115,450	153,989
1912	40,393	108,874	149,267
1913	33,567	25,952	59,519

TABLE II. CHARACTERISTICS OF ALLOY STEELS

Kind	Steel Containing	General Properties Anticipated
Titanium	0.1% metallic titanium	Less segregation, cleaner metal, hence, longer life.
Nickel	3.5% nickel	Increased life.
Nickel chrome	Containing varying percentages—nickel and chromium.	Increased life by being tough and hard.
Manganese	About 12% manganese	Very tough and hard, cannot be easily cut or drilled, wears slowly.
Electric	Made in electric furnace	Very clean steel, free from impurities, thus adding life.
High silicon	About 0.35% silicon	Increased life. Much used in England.

The reason assigned for this decline is the increased cost of alloy steels over that of openhearth steel, which is now being largely used for rails on account of its much higher wearing quality than bessemer steel, although its cost is higher by $2 per ton (or about 7%). The report states that openhearth rails made with the usual addition of 0.1% of metallic titanium, cost about 12% more than bessemer, while with manganese steel at $80 per ton, the cost is about 186% greater than for bessemer steel. As the use of openhearth steel has increased, the use of alloy steels has decreased. This refers to rails for both steam and electric railways. Quoting now from the report:

The first cost of alloy-steel rails therefore may be not only prohibitive in some instances, but in others so high as to render return on the investment extremely low, especially when a large sum is involved. These matters have doubtless militated against the production of alloyed steel rails, and purchasers have contented themselves with the adoption of openhearth steel on the reasoning that for 7% greater first cost, 50% longer life for the rails might follow.

Under special conditions of quick-wearing track, sufficient benefits may ensue to warrant the adoption of an alloy-steel rail, and the demand for alloy rails seems to be for track of this class. The question of what alloy to use is important. Eliminating matters of cost, the purchaser has ferro-titanium, manganese, nickel, high silicon and electric steel to chose from. It is unfortunate that rail sections are of an intricate and unbalanced character, the girder and high T-rails especially as these odd shapes preclude opportunity for successful heat treatment. However, some attention has been given to the heat treatment of rails.

Experience with alloyed steels is dependent on a number of factors in addition to the metal itself. The mere addition of 0.1% of metallic titanium or 13% of manganese to the steel will not be a panacea for the ills to which track and rails are subject. Reports of breakage and wearing qualities, therefore, are inclined to show divergent results, and even average

results for any particular kind of steel may be greatly exaggerated.

The best cases of rails are those where different kinds of steel are laid in the same type of roadway and subjected to [illegible] conditions and maintenance. Results from such [illegible] afford good comparison, but the tendency even then is to measure the rail wear by the eye rather than by accurate instruments, so that misleading figures may readily result.

In the use of alloyed steel on street and interurban lines, either the rails have not been in service sufficiently long to permit of a fair comparison being made, or else the matter of careful measurements has been somewhat neglected, so that the records are unsatisfactory. It is opportune to emphasize the fact that girder and high T-rails, as well as standard sections, can be easily rolled from the special steels noted in Table II, possessing the general characteristics mentioned.

An English Railway Trainshed

SYNOPSIS—The trainsheds of many large railway stations in England are of types quite distinct from those in use in this country. The accompanying article describes a recent design of a station at Birmingham which consists of transverse girders 275 ft. long, with four supporting columns, spanning the entire width of the station, and having framed between them rows of arch trusses of 40-ft. span. The methods of erection are described also.

The Great Western Ry., of England, has reconstructed and enlarged its Snow Hill station in Birmingham. The new trainshed is of a type practically unknown in this country. The station is a large one, with a track plan as shown in Fig. 1. Four main tracks run through the center, with a single track on the outer side of the two large island platforms, while at the north end of the station each of these platforms is split by a pair of stub

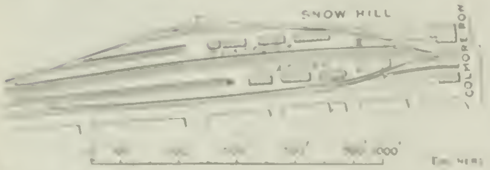

FIG. 1. TRACK PLAN OF THE NEW SNOW HILL STATION AT BIRMINGHAM (ENGLAND), GREAT WESTERN RY.

tracks about 400 ft. long. The two tracks of the longer stub converge to a transfer table (with radial tracks) located at its farther end, so that the engine of an inbound train can be promptly transferred to the outbound track and pass around the train. The six through tracks converge into a double-track approach at the south end (in a tunnel) and a four-track approach on a bridge viaduct at the north end.*

The main platforms are nearly 1200 ft. long, sufficient for two trains, this arrangement being necessitated by the fact that it was impracticable to widen the station, which is flanked by two streets. Each pair of tracks is connected by a double crossover at the middle, so that with two outbound trains standing on the same track (and heading in the same direction) the rear train can pull out ahead of the other if necessary. In the same way, a second inbound train can pass a train standing at the platform and then run onto the same platform track. There is also a trailing crossover between the two pair of tracks. This arrangement of double-length platforms is a feature also of the Victoria Station of the London, Brighton & South Coast Ry., at London, described in ENGINEERING NEWS, Feb. 11, 1909.

The switches and signals are operated from two towers by the Westinghouse all-electric interlocking system. Current at 110 volts is supplied from a storage battery charged by two motor-generator sets. The main platforms are 84 ft. wide, with 24-ft. clear width on each side of all buildings erected on the platforms for waiting rooms, etc. The spur platforms of the stub tracks are 300 to 500 ft. long, and 12 to 20 ft. wide. All platforms are 3 ft. above the tops of the rails.

TRAINSHED

This is the most interesting portion of the station from a structural point of view, and its general design is shown in Fig. 2. Across the entire width of the station extend parallel chord trusses resting on columns in the side walls and on two columns on the main platforms. These trusses are spaced 45 ft. 10 in. apart, and between them are filled trusses (about 15 ft. apart) having curved bottom chords and inclined top chords, with a monitor roof at the top. Thus the trainshed or station roof consists of a series of transverse ridges, or what is known in England as a "ridge-and-furrow" roof (quite different from the American "saw-tooth" type). The upper part of each ridge, on either side of the monitor, is covered with a skylight.

The long transverse trusses are 8 ft. deep, with chords 17 in. deep and 15 in. wide, as shown in Figs. 2 and 3.

*The [illegible] was described in [illegible], June [illegible].

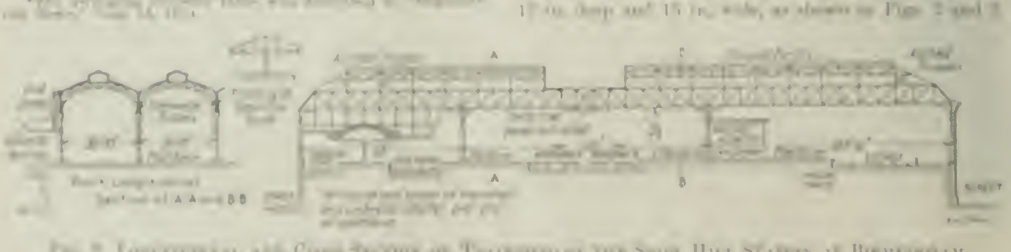

FIG. 2. LONGITUDINAL AND CROSS-SECTIONS OF TRAINSHED OF THE SNOW HILL STATION AT BIRMINGHAM (ENGLAND), GREAT WESTERN RY.

They are riveted up to form continuous girders, and are rigidly connected to all the four columns, as it was considered impracticable to place satisfactory expansion bearings on the tops of the light columns. The columns are designed, therefore, to take up any tension due to expansion and contraction of the 275-ft. trusses. There are 15 of these transverse trusses, so that the trainshed is 550 ft. long. The north end has a glazed screen, carried about 3 ft. beyond the main end trusses, as shown. The sides or walls also are glazed.

It will be seen from Fig. 2 that the end trusses and roofing are omitted over the five central panels. Two of these panels have a low ridge-and-furrow roof between the trusses, but the other three are left open to the air, thus providing a 22-ft. opening for light and ventilation. This shows also in Fig. 4. Along the south end of the trainshed (facing the headhouse) extends a covered footbridge over the tracks, with stairways to the platforms and inclined walks to the main entrance hall.

The arch trusses which are fitted between the main transverse trusses have their ends somewhat deeper than the main trusses, so that the end web members and the top chords of adjacent roof trusses are connected above the top chords of the main trusses. All the members are angles, and all the connection plates are made with curved outlines. A plank walk is placed in each furrow.

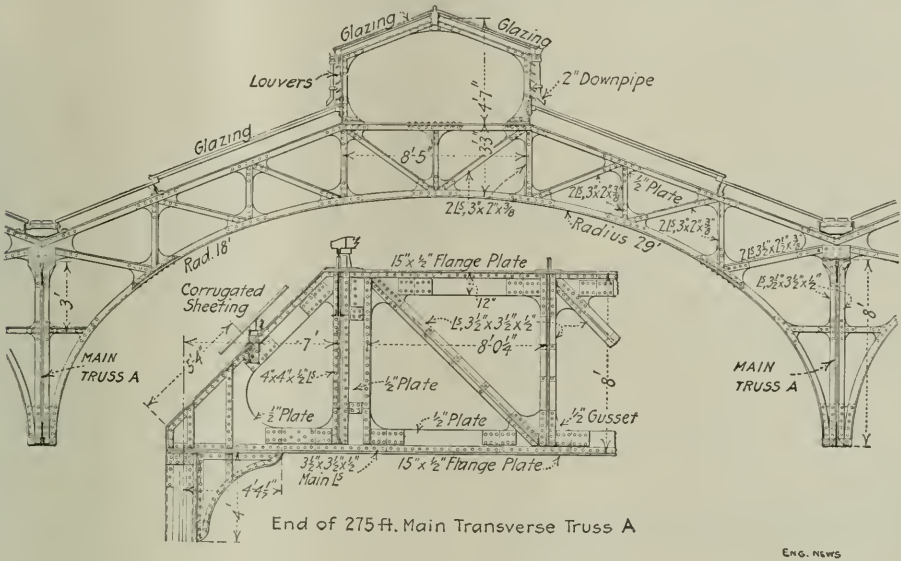

FIG. 3. TRUSSES OF THE NEW TRAINSHED

FIG. 4. SNOW HILL STATION AT BIRMINGHAM (ENGLAND), GREAT WESTERN RY., SHOWING THE TRAINSHED CONSTRUCTION AND BUILDINGS ON THE PLATFORMS

The platforms extending beyond the north end of the trainshed are covered by umbrella roofs or canopies. Each canopy has a single row of columns, 20 to 33 ft. apart, with a double cantilever arm on which are upright members to support the roof framing, as shown in Fig. 2. The columns are anchored to concrete blocks and are designed to resist a 50-lb. wind pressure. The clear height under the cantilever arms is 11 ft. 9 in., and the width of the canopy roof is from 20 to 38½ ft. The sides extend 18 in. beyond the platforms, and are faced with a wood screen whose lower edge is 13 ft. 6 in. above the rails.

Erection of Trainshed

The first step was the removal of the old arched roof, which had crescent-shaped trusses with both chords curved. Beneath this was erected a traveler having three

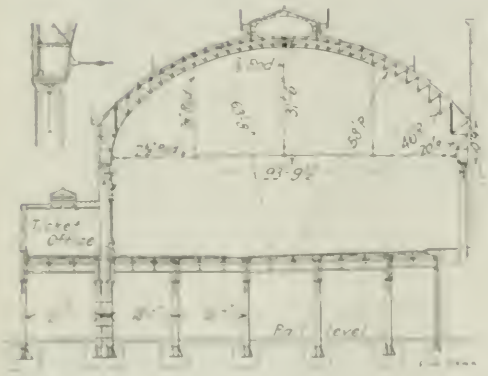

Fig. 5. Cross-Section of Main Entrance Hall, with Three-Hinged Arched-Roof Trusses

timber trusses with curved top chords carrying a curved deck that fitted close beneath the bottom chords of the old roof trusses. The ends of the traveler trusses were carried on timber towers with double-flanged wheels rolling on rails.

For the erection of the new trainshed, the two end portions of each main truss [illegible] from the wall columns to the interior columns [illegible] shipped and riveted completely [illegible] of maximum length [illegible] were shipped in two parts and riveted up on the deck before being hoisted into place. The [illegible] length of the center portion of each truss (between the interior columns) was shipped in two [illegible] sections and assembled in place. These [illegible] lengths were erected from a traveler having a track for a 7-ton locomotive crane of 14-ft. working radius.

The traveler had three [illegible] trusses [illegible] ft. apart, connected by lateral bracing and carrying I-beam joists and a plank deck. The ends of the traveler were supported by trestle towers on rails, the traveler being moved [illegible]. Pneumatic riveting hammers were used. The steel was [illegible] and erection [illegible]. The deck and wall [illegible] were then covered with [illegible], and after [illegible] coats of red lead, two finishing coats of paint were applied.

Arched Roof of the Entrance Hall

The main hall or entrance hall is about 93x165 ft., with a barrel arch roof composed of three-hinged arch trusses of 91 ft. span, 31½-ft. rise. On one side these rest on a lattice truss supported by two end columns. The height from the floor to the springing line is 22 ft.

This roof is shown in Fig. 5. The radius of the bottom chords is from 29 to 58 ft. The feet of each truss are connected by a tie rod, but instead of being attached to the shoe pins, the looped ends are attached to pin plates on the face of the bottom chord. The tie-rods have turnbuckles for adjustment, and to prevent sagging each rod is supported from the arch by three ⅞-in. hanger rods. There are seven of these arches, connected by trussed purlins. Above the arches is a wide monitor roof.

In erection, each arch was delivered in four sections. Each half arch was then assembled, riveted up, and raised by a derrick having a 75-ft. boom. This derrick held it in place until the other half was swung in the same way and the hinge pins were fitted into position.

Other Features of the Station

The Snow Hill station is built on sidehill ground and the adjacent streets are of varying levels and grades. The tracks are elevated above the general street level, the lower floor being utilized for station facilities and for stores fronting on the two side streets which limit the width of the station. At the south end, however, a main street crosses the tracks, and the main entrance is from this street so that the main passenger facilities are at this upper level. This street is reached by inclines from the two side streets. The hotel above the tracks has been converted into an office building for the division offices of the railway, with the main restaurant on its lower floor.

The main entrance hall is behind this building, having a 20-ft. approach corridor from the street, while on the west side is the carriage entrance, with a driveway extending into the hall so that passengers are landed close to the ticket office, booking room, parcels room, etc. From this main hall, two inclined walks lead to a [illegible] footbridge 20 ft. wide, across the end of the trainshed, with a 24-ft. stairway to each platform. The entrance hall is about 93x165 ft., and is [illegible] by heavy plate girders which give a clear headway of 14 ft. 3 in. above the rails. It has a barrel arch roof as described above.

One feature which is in marked contrast to American practice is that there is no spacious and elaborate general waiting room. Instead, separate and relatively small waiting rooms (for the different classes of passengers) are provided along the two main platforms, in connection [illegible] of [illegible] and [illegible]. Similar buildings contain the refreshment rooms, lavatories, offices, baggage rooms.

The design and construction of the new station was under the direction of Mr. [illegible], Engineer of New Works, Great Western Ry. The general contract was let to Henry [illegible] & Co., and the steelwork was built and erected by [illegible] & J. [illegible].

Railways of Queensland, Australia, according to the report of the Commissioner for the year ended June 30, 1914, [illegible] [illegible] miles, of which [illegible] miles [illegible] during the year. [illegible] [illegible] [illegible] have been [illegible] by Parliament [illegible].

Municipal Ownership and Operation of Water-Works*

By M. N. Baker†

The rapid growth both in the number of water-works and in the percentage of those works under municipal ownership was one of the marvels of the nineteenth century. The century opened with 16 works in the United States, only one of which was municipally owned. It closed with perhaps 3500 works, more than half of which were under public ownership and 200 of which had changed from private to municipal ownership. No statistics of ownership for the whole United States have appeared since "The Manual of American Water Works" for 1897, but it is known that changes from private to public ownership have gone on at a rapid pace in the last 17 years and it is believed that of the hundreds of new works built in that period the greater part are now owned by the city which they supply.

All of the major cities of the United States own their water-works until San Francisco is reached. Going over the whole list of cities which the Census Bureau estimates as having a population of 30,000 population and upwards it appears that in round numbers there are 150 municipal to 50 private plants, or 3 public to 1 private. If total populations supplied were considered, the preponderance of municipal ownership would be still greater.

Competing water companies have been few. Competing municipal and private works have been fewer still and such competition ends, sooner or later, with the city in full possession of the field. The reason for this lack of competition is that the water-supply service is one of the most complete natural monopolies in existence.

This natural monopoly feature and the close and vital relationship of public water-supplies to the health of water consumers and to the safety of both life and property from fire, go far toward explaining the rapid growth of municipal ownership of water-works and the persistent demand for a change from private to public ownership where the former prevails. It does not follow, however, that every city still under private ownership is in duty bound to acquire works of its own without delay. A variety of local conditions may determine the wisdom of continued private ownership for a few or even for many years. Good service under private ownership is increasingly possible each year, because the newer water-works franchises and contracts are more definite and fairer to each side than the older ones and because of the growing prevalence of state utility regulation. Nevertheless, no matter how far in the future matters of local expediency may throw municipal ownership it may well be the ultimate goal of every city, town and village that has not yet attained it.

Notwithstanding all that has been said and so well said in favor of home rule, I still believe, as I have long believed, that municipal as well as private water-works should be subject to state regulation. Even if in no other respect, there must be state regulation of the purity of the supply. This principle was recognized and put into effect in a number of states before state regulation of utility rates was thought of. Until recently, state regulation of the sanitary quality of water-supplies was always vested in state boards of health and with one or two partial exceptions this is still true.

The case for state control of the purity of water-supplies rests upon the fact that public health is a matter of state and national concern and cannot safely be left to local control. A city with a polluted water-supply does not stop with causing a high local typhoid rate—though this in itself is a proper matter for state interference. Such a city contributes in numberless ways to the spread of typhoid throughout the whole state and over the whole country.

Besides the question of purity, state control of water-supplies, regardless of ownership, is demanded to settle rival claims for sources of supply which two or a half-dozen cities may wish to draw upon. This matter is now being controlled by state boards of health in some states and by state water or state conservation commissions in others, but not often, if at all, by state utility commissions.

If time permitted I should like to present in detail the argument for state control of water-works accounts and reports of physical data. Where such control is now exercised, it is vested sometimes in a state board or commissioner or auditor of municipal accounts and sometimes in a state utility commission.

Coming to another phase of the subject, I believe that it would be salutary if there were some measure of state control over the way in which a city raises its money to defray the cost of its utility service. In the case of water-works, in particular, rank injustice now prevails in the distribution of the cost of the service between the private consumer and the city at large. I believe the Wisconsin Commission has taken a long step in the right direction in compelling some cities to raise by taxation an adequate sum to pay for fire protection and other public services instead of saddling this charge upon the private consumer. The whole water-works fraternity of the country has for years urged that the taxpayer and not the private water consumer should meet the cost of fire protection, street watering, sewer flushing and the water-supply to public buildings.

Possibly some of you may have observed that such instances of state regulation of water-works as I have specified are vested in four independent commissions: (1) health; (2) water-supply or conservation; (3) utility; (4) accounting or auditing—and there may be still others. Some of these commissions have overlapping jurisdictions. Strongly as I believe in state administrative control of municipal affairs, I do not wonder that there are complaints of over-regulation when there are so many municipal masters—although even a multiplicity of state administrative boards is infinitely better than the old-time state legislative interference which these boards are lessening.

Distasteful as any sort of state control may seem to some, cannot we all agree upon the desirability of placing all such control as may from time to time exist under one instead of many commissions—a single State Board of Municipal Control, under which there would be a bureau for each branch of the municipal service subject to state supervision, the whole working in harmony and so centralized in administration as to give one instead of many municipal masters?

*An address before the Conference of Municipal Mayors on Public Policies as to Municipal Utilities, Philadelphia, Penn., Nov. 14, 1914.

†Editor of "Engineering News," New York City

The Hell Gate Bridge in the Shop

Progress in building the Hell Gate Bridge across the Narrows of the East River between Long Island City and Ward's Island is in accordance with schedule. The steelwork of the 977½-ft. steel arch has been in course of fabrication at the Ambridge, Penn., plant of the American Bridge Co. since early this year, and in May was begun the yard assembly of portions of the arch, which is required in order to make the joints true and assure accurate and easy fit in field erection.

Meanwhile, the work at the site has been advanced, after completion of the piers, by beginning the erection of the towers and temporary backstays which are needed for the erection of the arch by the cantilever method. The program is based on finishing with the backstays during winter, so that erection of the arch itself can be started at the earliest possible time in spring, 1915, and thus give the whole season for erecting and swinging the arch.

A full description of the Hell Gate steel arch, with drawings of typical parts of the steelwork, will be found in ENGINEERING NEWS of Jan. 8, 1914, pp. 59 to 64. The chief features of this bridge from the standpoint of the shop which must fabricate the steelwork are:

(1) The use of high-strength medium steel throughout. The demanded ultimate tensile strength is 66,000 to 76,000, with a desired value of 71,000 lb. per sq.in. The material must meet a cold-bend test of 180° around a diameter of twice the thickness.

(2) The enormous size of the individual members and of the plates which compose it; and more especially the size of gusset plates.

HIGH-STRENGTH CARBON STEEL

The steel at first furnished under this contract ran generally down toward the lower limit of the demanded strength-range, that is, near 66,000 lb. With further efforts, however, the deliveries were of stronger material, and at the present time the average of the tests runs rather over the required average, probably near 72,000 lb. per sq.in. The carbon content of the material varies, to suit the thickness of material (ranging from ½ in. to 2 in.). The ordinary amount is in the neighborhood of 0.30%.

LARGE SIZE OF PARTS

Some of the most difficult pieces to furnish are the large gusset plates, extending through the entire depth of the heavy chord or arch rib and projecting up to take the web members. The largest such plate is 129 in. wide by 17 ft. long and 1⅛ in. thick. Some of the [illegible], with plates [illegible] in. wide, are heavier, but the large gusset [illegible] is at the extreme limit of the capacity of available rolling mills. Doubt was entertained from the start by the shop people whether these large plates would be obtained reasonably straight (flat) and of uniform thickness (i.e., without swell in the middle of the width). Overrun of thickness would make trouble in entering the gussets into the slots in the chord which receive them (see Fig. 2, where the slots are seen just outside of [illegible] in Fig. 2 a [illegible] slot is seen [illegible] of the arch rib which is seated on the [illegible]).

YARD-ASSEMBLY

The fabricating processes in this contract are unusual not only because of the conditions just mentioned but also because of two other requirements: that practically all the holes must be drilled (subpunching is allowed only in ½-in. and less thickness), and that the structure must be assembled in the yard and the field connections drilled to match before the parts are shipped. This last requirement is reflected in the accompanying views, Figs. 1 and 2.

As might be expected from the great size of the structure, it was not possible to yard-assemble the entire arch (i.e., one truss) simultaneously. The assembly of three or four panels at a time was, therefore, taken as satisfactory, but the terminal members of each section are later reassembled with the following section to get the match of the connection.

The view, Fig. 2, pictures the four end panels of the arch; the endpost is the farthest member in the view, the upper chord is at the right, and the lower chord or main arch rib is at the left. In Fig. 1 the lower chord is the farther member and the endpost is at the right.

POLYGONAL-FACED CHORD JOINTS

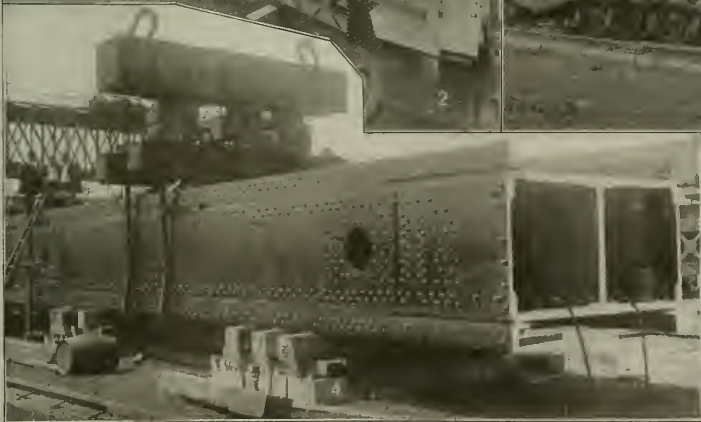
Planing the chord joints is one of the special features of the work, in view of the great size of the parts. This work is done on a traveling-head planer, housed in the shed at the right in Fig. 1 and in the background in Fig. 2. Only one end of the member being planed is in the house, the larger part of the length being outside. The roof of the planer house is removable, so that the yard gantry can lift the piece away or turn it, as may be needed.

This yard gantry was built specially for the work in hand. It is 130 ft. in span and has a capacity of 150 tons, although it will be called upon to lift loads of about 185 tons, which its normal overload capacity permits it to handle.

The main arch rib is of the section exhibited by the piece in the planer in Fig. 1, a box section with horizontal diaphragm at mid-height. The width of the section is 7 ft., and its depth varies from about 7½ ft. at the crown of the arch to 10½ ft. at the abutments (the face shown in Fig. 2). This rib is field-spliced at each panel-point; the joint faces are planed to a polygonal contour, which gives contact over only the middle third of the depth of the section, while the upper and lower thirds are backed off on a taper amounting to $\frac{1}{16}$ in. each at upper and lower flanges. Thus, when the two adjoining sections are butted together in correct relative position, there is an opening of ⅛ in. at top and bottom, with the middle third of the depth in true bearing.

The original requirement of the engineer was that one of the abutting faces should be finished to a slight circular or rocker curve, the other face being plane; but this requirement was, upon consultation with the contractor, modified to give the polygonal outline just described.

In facing the first rib sections fabricated, early the past summer, they were planed on the true joint planes for the full depth of the section, and the first yard assembly was done with the rib sections in this condition. The purpose was to see whether joints could be obtained so true and accurate as to make the polygonal planing unnecessary. On assembling, it was found that the joints made perfect contact. However, the engineer preferred to make still more certain of uniform stress distribution



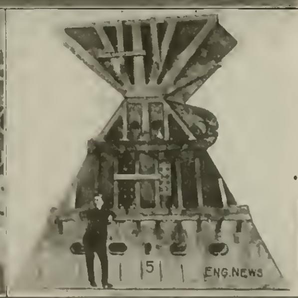


FIG. 1. END SECTION OF ARCH ASSEMBLED IN AMBRIDGE SHOPYARD

(Top chord in foreground, end-post at right; at extreme right, under the 150-ton yard gantry, is the planer house, with a bottom-chord section in place for planing the joint face.)

FIG. 2. ANOTHER VIEW OF THE FOUR-PANEL PIECE OF THE ARCH ASSEMBLED IN THE YARD

(The joint in the right foreground is one of the top-chord panel-points, which have much smaller gusset-plates than those of the bottom chord.)

FIG. 3. END SECTION OF BOTTOM CHORD, ON CARS FOR SHIPPING

(Weight as stripped for shipping, 150 tons; weight with gussets, etc., 185 tons.)

FIG. 4. ONE OF THE BOTTOM-CHORD SECTIONS IN THE YARD

(Note special lifting shackle. The end of the member shows the slots in which the web gussets must be entered to full depth of chord, during erection.)

FIG. 5. END SHOE OF HELL GATE ARCH

be adhering to the [illegible] requirement of [illegible] outline.

EXCELLENT SHOP WORKMANSHIP OBTAINED

The drilling of rivet holes is distinctly slower in the high-carbon steel of this bridge than in normal structural steel; with this exception it may be said that the material works just as easily as any bridge steel. Both the bridge-works officials and the engineer for the bridge say that the shop operations and the workmanship of the finished parts have been in all respects satisfactory. The rivets in the principal members of this bridge are of 1⅛-in. diameter. These are practically identical in material and strength with ordinary bridge rivets.

The group of views also contains a view of one of the end shoes of the arch. Such a shoe built up of steel castings with [illegible] total thickness weighs 500,000 lb. Inasmuch as it sits on a masonry seat inclined about 15° to the horizontal, provision was made for anchoring it in place until the arch is so far erected that the thrust of the structure will hold the shoe securely to its seat. Ears have therefore been cast on the upper member of the shoe, as will be seen in Fig. 5. These will be linked to eyebars [illegible] horizontally into the pier masonry just above the shoe level. After completed erection of the arch, the pins connecting the ears to the eyebars will be removed, the eyebars cut off close to the masonry, and the omitted blocks of facing stone at the location of the eyebars will be set in place.

The end casting of the arch, shown in place on the shoe, has a slightly convex cylindrical face, to give hinge action. A dowel connects the large castings to prevent displacement transversely.

The American Bridge Co., who is fabricating the steelwork, will also erect the arch, and is at present erecting the falsework already mentioned. Gustav Lindenthal, 68 William St., New York, is engineer for the owner, the New York Connecting Railroad Co.

A Year of Commission-Manager Government at Lakeland, Fla.

By [illegible] F. McLean*

The commission-manager government of Lakeland, Fla., the first of its type in the state, came into power in January, 1914. There was no great demand for the commission form of government in Lakeland, only a small vote was polled, and the majority was small. As a consequence, the new form of government has not had a strong backing of public opinion to encourage its efforts for efficiency in public service. Moreover, there has been considerably active opposition. This, at one time, took the form of a largely signed recall petition, which was eventually withdrawn. In spite of lack of support, the first year of the new government has not been barren of favorable results, as will be shown by mentioning some of the changes and improvements made by the various departments of the city.

THE SANITARY DEPARTMENT—This department looks after garbage collection, street cleaning and cleaning of outdoor closets. Although the city has a population of only [illegible] less than [illegible] the building lots are large, many of them having frontages up to 135 ft., and the limits include an area of about 4 sq.mi. The central part has modern sewerage, and a sewage-disposal system with Imhoff tanks. The care of the outdoor closets outside of the sewer zone, and the collection of garbage from the area of 4 sq.mi., constitute the most important duty of the sanitary department.

The following improvements have been made: A general cleaning up of all the alleys, the connecting up of a large number of buildings with the sewers, substitution of quicklime for antiseptics in outdoor closets instead of expensive coal-tar derivatives, a saving of $85 per month by having the head of the sanitary department take over the plumbing inspector's duties in addition to his own, a reduction of about $40 per week in the labor payroll; prompter and more reliable collection of garbage, introduction of "white wings" cleaning on the business streets; changes in the plumbing code, providing for the examination of all plumbers before granting them licenses, and putting all plumbers under bond to the city.

THE STREET DEPARTMENT—The business section is paved with brick and part of the residential section with bituminous concrete, but there is a large extent of sand-clay streets and unpaved roadways. As the cleaning of the paved streets is done by the sanitary department, the principal work of the street department is the maintenance of the sand-clay and unpaved streets. The split-log drag has just been introduced, and is found of great service. The street department has been given, lately, the repair work on paved streets necessitated by the trenching operations of plumbers and others, the cost of the work being charged to those doing the trenching.

FINANCE DEPARTMENT—A budget system of twelve divisions has been developed, instead of the old method of throwing everything outside of the light and water fund into a general fund and a sinking fund. Part of the floating debt due to the old system is being taken care of in the first budget of the new system, which, if carefully adhered to regarding expenditures in the different divisions, will clear off the floating debt in a few years.

FIRE DEPARTMENT—Improvements have been made in the present alarm system by putting in an extra telephone, connected with a large gong, and by having a direct connection from the telephone at the waterworks pumping station to the fire whistle. The citizens have voted to secure money to put in a modern noninterfering box fire-alarm system, a pumping engine, and other apparatus.

POLICE DEPARTMENT—The following improvements have been made in the police department: Patrolmen are required to report their whereabouts to headquarters half-hourly by telephone; data concerning all arrests are entered on printed forms by the patrolmen at the time of the arrests.

WATER AND LIGHT DEPARTMENT—The citizens have voted to sell bonds to enlarge the present overloaded power house and to extend and renew the water-distribution system. This enables the department to lower the rates to consumers, as a large part of the revenue has been expended, heretofore, in installing new mains and other relatively permanent parts of the distribution system. A commencement in lowering the rates has been made by cutting the minimum charge for water to $0.75 per month and for light to $1 per month, as against $1 and $1.50 per month for water and light, respectively. Further reductions will be made, because now only the interest on

*[illegible] Lakeland, Fla. [illegible]

permanent improvements will be paid from revenue, outside of small payments on a sinking fund.

There have been large losses in the past through customers neglecting to pay bills when they changed their places of business or residence. This has been largely obviated through prompter rendering of bills, and discontinuing service to delinquents.

Long-Term Variations in Stream Flow, Croton and Hudson Rivers

By Edward H. Sargent*

The writer has made an investigation of the two longest stream-flow records in New York State, the Croton River (1868 to 1913) and the Hudson River (1888 to 1913), with an idea of finding their diversity of flow.

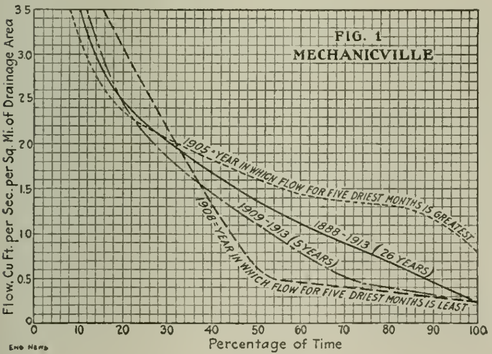
On the accompanying diagrams (Figs. 1 and 2) are shown Duration Curves† for the Hudson River at Mechanicville (drainage area 4500 sq.mi.) and the Croton River at New Croton Dam (drainage area 360.4 sq.mi.). Curves are given for both places for the long-term record, the driest‡ year, the wettest‡ year, and the last five years, 1909 to 1913, inclusive.

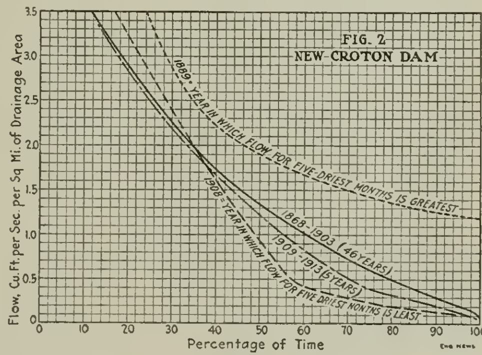
voir was but slightly in excess of the wettest year (1892) prior to its construction.

It was found that to obtain a duration curve for recent years that would closely approximate the low-water portion of the long-term duration curve at Mechanicville, it was necessary to use the records for the last eleven years. In any duration curve computed for any series of years from 1913 backward less than eleven years, the curve will lie below the low-water portion of the long-term record curve.

The Croton River curves were based on the computed natural flows of the Croton River at the New Croton Dam. The estimates of the flows from 1868 to 1899 were made by John R. Freeman, and from 1900 to date, by the Croton Aqueduct Commission and the Department of Water Supply, Gas and Electricity of the City of New York.

The driest year of the Croton River records was 1908, coinciding with the driest year shown by the Mechanicville records. The wettest year shown by the Croton River records was 1889. Similarly, as in the case of the Mechanicville records, it was found that if a duration curve was computed and plotted from the records of the Croton River for the last eleven years (1903 to 1913, inclusive) it would closely coincide with the low-water flow





Duration Curves of Flow of Hudson and Croton Rivers

(Based on monthly records at Mechanicville and at New Croton Dam.)

The Mechanicville curves are based on the records taken at the plant of the West Virginia Pulp & Paper Co. and represent the combined wheel and spillway discharges, which have been checked at various times by current-meter measurements. These flows do not represent exactly the natural runoff from this watershed because of the diversion of approximately 200 cu.ft. per sec. to the Champlain Canal during the navigation season, May 1 to Dec. 1. The natural flow since 1899 has also been somewhat modified by the storage in the Indian River Reservoir, 1,700,000,000 cu.ft. capacity. In view of this storage it is pertinent to note that the driest year (1908) during the entire period 1888 to 1913 was subsequent to the con truction of this reservoir. The wettest year (1905) subsequent to the construction of this reser-

portion of the long-term record, and any duration curve for any series of years from 1913 backward less than eleven years would lie below the low-water portion of the long-term record curve.

The following is a table of the rainfall on the Croton watershed for the various periods for which the duration curves are shown:

Period	Rainfall, In.
1868-1913	48.82
1903-1913	49.22
1909-1913	47.43
1908	43.02
1889	55.70

Rainfall stations have only recently been established on the Hudson River watershed at points which will give an idea as to the precipitation at the higher altitudes, so that it is not possible to determine with a great deal of accuracy the rainfall for the Hudson River watershed.

*Assistant Civil Engineer, New York State Conservation Commission, Albany, N. Y.

†See article on "Stream Flow Studies" by the writer in "Engineering News," April 23, 1914.

‡The "wettest year" has arbitrarily been defined as that year in which the runoff for the five driest months was the greatest, and correspondingly, the "driest year" as the year in which the flow for the five driest months was the least.

Dock Facilities at Guayaquil, Ecuador, are such that most of the unloading is done by lighters. This, however, appears to be partly due to the fact that it is necessary, or at least advisable, for ships to keep away from the docks in order to lessen the danger of infection by bubonic-plague rats.

Flood-Protection Work on Fall Creek at Indianapolis, Ind.

By [illegible] E. White*

The work of providing for flood protection along Fall Creek began while the 1913 flood was at its crest.[1] At that time high-water elevations were taken at each of the 12 bridges crossing the creek and at all points around the flooded margin. The former figures were used in connection with establishing the grade and cross-section of the stream, while the latter were used in making a flood map, which was used as a basis for determining the assessments to cover the cost of constructing the new [illegible] embankment. The elevations and conditions at the bridges are given in the accompanying table. Fig. 1 is a map of the park district along the creek and shows the new work.

Immediately after the flood a survey of the creek was made, extending from its mouth to a point eight miles up stream. This survey was made with transit and stadia and cross-sections of the stream were taken at 100-ft. intervals. These sections were plotted and were found to range from [illegible] sq.ft. to [illegible] sq.ft. in area. Some of the sections are shown in Fig. 2. One section (A in Fig. 2) between the Fairgrounds bridge and the C. I. & W. R.R. bridge carried all the water that passed down the creek. This section contained 1100 sq.ft., with [illegible] sq.ft. in the channel proper, and with a stream grade of [illegible]%. From these data a maximum flow of [illegible] cu.ft. per sec. was computed. In determining the necessary cross-section to provide for future floods the foregoing 1100-sq.ft. section was used as a criterion.

*Engineer, Department of Public Parks, Indianapolis, Ind.

[1] [illegible]

If the grade and section of the channel had been uniform throughout, naturally a 1100-sq.ft. section would have been required at all sections, or if the cross-section had been uniform and the grade had been variable, the velocity, and consequently the flow, would necessarily have changed. But as both the cross-section and grade were variable, both factors had to be considered in establishing the new grade and section of the channel in order to get as nearly as possible a uniform flow.

Another factor that entered into the question of uniform flow was the capacity of the different bridges and the effect of the Indianapolis Water Co.'s dam at Northwestern Ave. The top of the dam is level with the bed of the stream at a point half way between Central Ave. and College Ave. (see Fig. 1), and this last named point is 8 ft. below the bed of the stream at the Fairgrounds bridge.

If the Board of Park Commissioners were to dredge to a depth of 8 ft., the dam would back the water to the Fairground bridge. This being the case, at flood stage the stream grade would be practically 0.1% and uniform. Then with a section of at least 1100 sq.ft. there would be no doubt as to the efficiency of the channel; the only question would be as to the waterway of the bridges. After the creek has been dredged, all irregular-

FIG. 2. CROSS-SECTIONS OF FALL CREEK, SHOWING IMPROVEMENTS

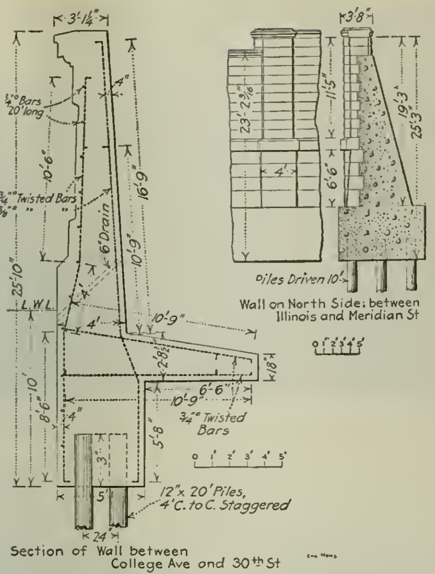

FIG. 3. CROSS-SECTIONS OF RETAINING WALLS ALONG FALL CREEK

ities in the bed will tend to be removed and those bridges not resting on piling will be endangered. However, a minimum section of 4100 sq.ft. has been adhered to, and the Board of Park Commissioners will dredge to a minimum depth of 8 ft. and a maximum of 16 ft. As the 1913 flood water all passed through the Illinois St. bridge, having a waterway of 2825 sq.ft., and on a section of the stream whose grade is 0.01% at that point, a sectional area of 4100 sq.ft. seems to be ample.

The first thing in the construction of the boulevard was the removal of the good soil from beneath the proposed roadway, and the storage of it on either side so as later to be available for surfacing the lawns. This is shown in section *B*, Fig. 2. The portion *Z* was removed with slip and wheeled scrapers, and stored at *X* and *Y*. Then the gravel excavated from the creek was hauled in to make the roadway and fill; when this work is nearly up to grade, the material at *X* and *Y* will be brought to the finished cross-section and grade.

The fill for sections Nos. 1 and 3 (Fig. 1) is being made from excavations from the creek, while that for section No. 2 is being made from material obtained from the grading of streets, excavations from cellars, etc. Along sections 1 and 3 the channel will be excavated to a depth of 8 ft. minimum and 16 ft. maximum and will have at least a 100-ft. base width at right angles to the center line of the stream. Section No. 1 is being constructed by the use of four stationary dragline excavators, stationed at intervals along the work. The material is dredged from the creek and dropped into small dump cars, which operate along the line of the work. These dump cars are pulled by an automobile mounted on car wheels, and a trip forward and back can be made in a very short time.

Where the sand and gravel taken from the creek is in excess of that needed for the embankment, it is stored and sold. The cost of constructing this section is about 12c. per cu.yd.

Section No. 3 is being constructed by the use of one dragline excavator and two trains of dump cars, pulled by dinkey engines, which carry the excavated material forward and back along the embankment. As on section No. 1, the excess sand and gravel is stored and sold. The cost of constructing this section is about 20c. per cu.yd. The cost of constructing section No. 2 will be between 20 and 25c. per cu.yd.

The cross-section of the boulevard embankment is shown at *B*, in Fig. 2. The width of the boulevard at the top is 75 ft. in nearly all cases, but in a few instances it has been made wider, in order to increase the height of the inside berm without making the increase noticeable. The width comprises a roadway 40 ft. between curbs, an inside berm of 5 ft. and an outside berm of 30 ft. The inside berm has a variable slope from 1 on 4 to 1 on 1½, while the outside berm has a slope of 1 on 1½ ft. Both berms have a slope of ¼ in. per ft. toward the roadway. The 30-ft. berm carries two rows of trees: one row being 2½ ft. from the property line and the other 6 ft. from the curb line. This berm also carries a 6-ft. walk at 5 ft. from the property line. The lawns have 2 ft. of good top soil, while the roadway consists of gravel.

At points along the creek from Capitol Ave. to Central

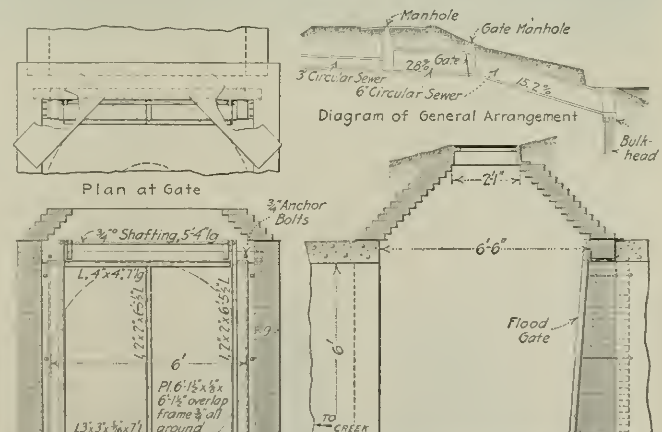

FIG. 4. FLOOD GATES FOR SEWER OUTFALLS ALONG FALL CREEK, INDIANAPOLIS, IND.

Ave., where property values are high, the boulevard is built so closely to the creek that it is necessary to have a retaining wall, not only to carry the embankment, but to give a greater section of channel. The sections of these walls are shown at the right in Fig. 3. They were built shortly after the flood of 1901.

Fig. 5. New Levee and Boulevard along Fall Creek, Indianapolis (Looking West from Northwestern Ave. Bridge)

Fig. 6. Building New Levee with Steam Shovel and Dump-Car Trains

A retaining wall between College Ave. and 30th St. was made necessary by the 1913 flood and is now under construction (Fig. 9). This wall will still slip the stream as shown by section C in Fig. 2, so that present conditions extend into the stream. As only a portion of the backfill will be made at this time, the wall had to be designed so as to withstand a high-water level with no backfill and also to carry a backfill in time of low water. Since this was to be a reinforced-concrete wall, these conditions made it necessary to reinforce the face as well as the back of the wall.

In addition to protection by walls and boulevard embankments, protection from backwater through sewers became necessary. Every sewer emptying into the creek was provided with a steel flood gate, as shown in Fig. 4. This gate was hung in a manhole constructed either at the top of the embankment or within the flood channel; otherwise the top would be raised by the water pressure and flooding would result. Of course, this makes it impossible for surface water to get away during a flood, but it is anticipated that this water will escape before the

Fig. 7. Building New Levee by Drag Scrapers and [illegible]

Fig. 8. River Wall and Fill of Flood-Protection Work on Fall Creek, Indianapolis, Ind. (Showing the Illinois St. Bridge)

creek reaches the elevation at which the gates will close.

With the completion of the work now under construction, Fall Creek will be harnessed as far south as the canal (Fig. 1). It is the intention of the Board of Park Commissioners to extend the boulevards southerly on both sides of the creek as rapidly as possible.

Fig. 5 is a typical view of the new bank and boulevard. The two sides of the fill are of earth, while the roadway fill between them is of gravel several feet deep; the gravel fill may be seen in the distance, to the left of the big trees. Fig. 7 shows a drag scraper plant making the fill north from 30th St. to the Fairgrounds bridge. The scraper cable is carried across the river; the bucket works across the bed and dumps the gravel at the tower, where screens are fitted, separating the gravel from the sand. From this the sand flows through the chutes to form the fill. Fig. 6 shows the fill being made by steam shovel and dump car. Fig. 8 is a view looking west toward the Illinois St. bridge, where the river is confined between masonry walls supporting the fill.

Aluminum Alloys as Surface Protection for Metals Subject to High Temperatures

A process has been developed by the Research Laboratory of the General Electric Co., by which aluminum alloys are formed on the surface of metal articles, particularly iron, steel and copper, and by which they are made more resistant to oxidation at temperatures above a red heat. This process has been called "calorizing." Articles may be heated in revolving drums with mixtures containing finely divided aluminum or those pieces which, because of shape or size, are not adapted for tumbling may be treated by packing them in or painting them over with the aluminum mixtures before heating. In this way the size of the heater which can be employed is the only limitation on the size of the piece that may be treated. Wire or ribbon may be treated by a continuous process, in which it is passed through a heated pipe containing the proper mixture.

The life of the coating seems to depend on the temperature at which it is used, as well as the duration of time allowed for the formation of the surface alloys. Long use at temperatures in excess of 1100° C. results in destruction. The thickness of the alloy formed varies with the length of time to which the piece is subjected to the process. The percentage of aluminum varies through the coating, being greatest at the surface. On a calorized copper rod the line between the alloy and the unchanged copper is sharp, but the color of the alloy varies from golden yellow next to the copper to silver white at the surface. Cross-sectional photo-micrographs show the large crystals of the calorized surface and the typical crystalline structure of the copper beneath. Some blistering of the copper immediately below the calorized surface is indicated by spaces between the copper crystals. If the process is conducted at a high temperature and the mixture is rich with aluminum, two layers of different alloys may result.

When an iron pipe or ribbon is calorized for a heating unit, the resistance and temperature coefficients are changed; the thicker the calorizing coat, the greater the change. The dimensions and weight of either a copper or iron piece are slightly increased by the process. The increase of dimensions is much less than the thickness of the alloy coat. There is a tendency to a greater increase at the edges than on flat surfaces.

Calorizing is not intended to compete with galvanizing, sherardizing, and similar processes for protection against corrosion at low temperatures, although for low temperatures calorizing is effective against the corrosion of copper as well.

The theory of the effect of the aluminum in the surface alloy is that a thin coat of aluminum oxide forms to prevent further attack of the metal beneath. This is similar to the protection which aluminum articles receive under some conditions.

Several recent typical examples of this protection are described in the October issue of the *General Electric Review*. Two pieces of similar iron pipe, one plain and the other calorized, were heated side by side with a laboratory blast lamp to a temperature of about 900° C. for four hours, then cooled and the heat reapplied for another period of four hours. At the end of that time the untreated pipe was badly burned, the metal being reduced at the point of the flame to one-half original thickness. The whole surface was blistered. The calorized pipe appeared to be unchanged. Previously, the calorized piece had been used in an electric resistance furnace where it was heated alternately to 1000° C. and cooled, being maintained at the maximum temperature in all for about 50 hours. The same piece was heated to about 900° C. and plunged into cold water after it had cooled to a dull red. On repeating this three times, the surface showed no signs of crack or scale.

Two pieces of sheet-iron tube, one calorized and the other plain, were subjected to a temperature of 800° C. in a gas furnace for 100 hours. The plain piece was practically destroyed, while the calorized piece was unharmed. An untreated piece of the iron wire or ribbon, such as is used in electric heating units, will burn out in four or five hours at the most, whereas the calorized strips have their life increased at least fifty times and in some cases over one hundred times. A life of 500 hours at a temperature of 800° C. may be expected from calorized heating units.

Calorized seamless iron tubing is being used for combustion tubes in the company's laboratory where pure oxygen is brought in contact with the metal at temperatures of 900 to 1000° C. These appear unchanged after 100 hours' service.

In some cases calorized copper may be used in place of aluminum bronze. In one large power station, which was having trouble from early corrosion of aluminum bronze condenser tubes, a set of calorized copper tubes were installed and in the 2½ years since not one has failed, whereas before the tubes would fail in four to six weeks. Railway controller contacts which had been calorized showed double the life of ordinary untreated parts.

Railroad Ice Storage Houses are the subject of a report which a committee of the American Bridge & Building Association presented at the recent annual meeting. The report is very complete, and in effect constitutes a treatise on the design and construction of such houses. Following a seven-page résumé the necessities of railway ice storage house design and the details of construction, the report contains some 60 pages of detailed description of houses which have been built by various American railroads. Copies of the report probably can be obtained from the secretary of the Society, C. A. Lichty, 319 No. Waller Ave., Chicago, Ill.

Field and Office

Plant and Working Methods on Approaches to North Side Point Bridge

By E. L. Jones*

The erection of two steel spans across the Allegheny River at the extreme point of land where the Allegheny and Monongahela rivers form the Ohio, and at a height of 72 ft. above pool level and 40 ft. above the sloping banks of the river, made it necessary to construct 900-ft. approaches on both sides with a grade of 5%. The approaches as well as the bridge itself are 56 ft. wide with a 36-ft. roadway and two 10-ft. sidewalks, provision being made for two car tracks on the roadway.

The south approach was designed with the idea of utilizing the present approach to the Point Bridge over the Monongahela. This idea was carried out by building reinforced-concrete retaining walls on both sides to widen the approach and raising the street to the new grade by making an earth-and-slag fill. This change in the old approach to the new grade made it necessary to raise the shore span of the old Point Bridge 2 ft. 7½ in. The remaining gap between the intersection of the center line of the two bridges and the new bridge was spanned by two reinforced-concrete arches with a clear span of 7[illegible] ft. 6 in. and 82 ft., respectively.

As conditions were different on the north side of the river, it was found advisable to use six reinforced-concrete arches diminishing from a clear span of 85 ft. at the river to a span of 39 ft. 4 in. at the last arch. From the abutment of this arch to the intersection of the approach with South Ave. [illegible] reinforced-concrete retaining walls were used with an earth-and-slag fill to grade.

The retaining walls were designed by three types, all, however, having spread footings to distribute load over a greater area. Walls up to 15 ft. in height were of the gravity type. Those from 15 to 34 ft. in height were designed as cantilever walls, while those over 34 ft. were all built with counterforts.†

Because the ground on both sides was all filled, consisting of a porous nature, concrete piles were driven under all walls and piers with the cutoff from 8 to 12 ft. below ground level. The arches are of reinforced-concrete rings the full width of the approach, diminishing slightly in thickness under the sidewalk. Spandrel walls carry the flat roadway slab while the sidewalk rests on the side walls and roadway slab.

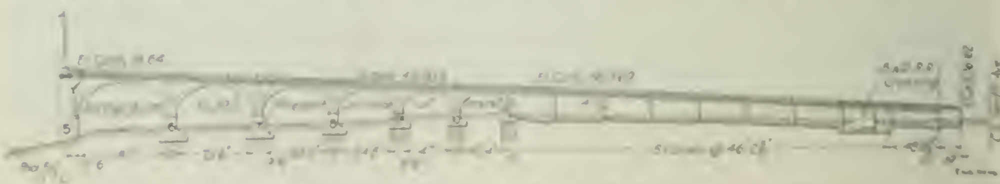
The steel spans over the river were erected by the American Bridge Co. in 1911-12, but, because the City of Pittsburgh had no available money, the contract for the approaches was not let until early in 1914. They are slated to be finished July 1, 1915, at an estimated cost of $575,000.

The work comprises some 15,000 cu.yd. of excavation, 17,300 cu.yd. of plain and reinforced concrete, 600 tons of structural and reinforcing steel, 13,000 cu.yd. of slag fill, 28,000 lin.ft. of concrete piles, also handrail, sewers, paving, sidewalks, etc.

Mixing Plant

Immediately after the contract had been let, the contractor began erecting his plant and getting equipment on the ground, but there was not much that could be done until spring. As all sand and gravel used on this work was dug in the Allegheny River and delivered to the job in wagons, it was necessary to lay out the mixing plants with this in view.

On the south approach the mixing plant was located opposite pier No. 2, in order to take advantage of the sloping ground, which ran up to the present Point Bridge approach, as by building a short trestle, level with the approach, teams were able to dump sand and gravel into the top of the 50 and 60-cu.yd. storage bins. Under the bins was a ⅔-cu.yd. Ransome displacement mixer with concrete hopper attached. Concrete was dumped directly into a [illegible] hoist bucket and hoisted to the top of a 70-ft. wooden tower, from which it was distributed by one especially built concrete chute supported on a 30-ft. latticed boom, which also held up one end of a 20-ft. trussed chute, thus making a full radius of 100 ft. and enabling the contractor to place concrete at any point on piers and arches No. 1 and No. 2, and, by adding 100 ft. more, three sections of wall could be reached. The remainder of the walls were concreted with a ½-cu.yd. Ransome mixer placed on top of the wall and moved ahead by a locomotive crane, which ran on a track parallel to the wall. The capacity of this crane was 15 tons. It had a 50-ft. boom and was used for all wall excavation and to move forms from one section to the next.



North Approach to North Side Point Bridge (Elevation of East Wall)

*[illegible]

†[illegible]

Excavation for pier No. 1, which was 34 ft. deep, was done with a guy derrick handling a 1-cu.yd. dump bucket. This derrick was afterward moved onto the north end of the bridge and used to assist in setting and removing steel centers. Cement was delivered in cars to within about 1000 ft. of the plant; but from that point was hauled in wagons to the top of the bins and dumped down a wooden chute to the mixer. A storage shed for 800 bbl. was provided. With a few minor exceptions, the arrangement of the mixing plant on the north end was the same as on the south end.

All excavation on the north end was done with a $\frac{3}{4}$-cu.-yd. orange-peel bucket, operated by a 30-ton locomotive crane with a 70-ft. boom. This crane was also used for setting arch centers, handling wall forms and placing concrete in the walls. The large mixing plant was located so as to chute concrete to all parts of the six arches, while the walls were taken care of by the same method as that employed on the south end.

Piles

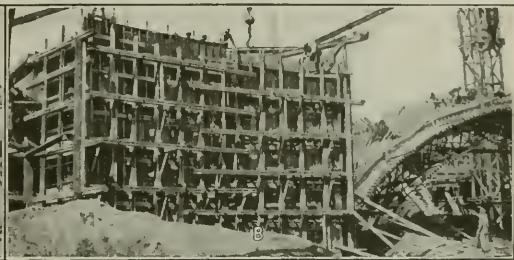
As soon as the excavation on the first pier had been carried down to the required depth, the work of driving the piles was started. The piles were placed 3 ft. c. to c. each way, over the entire bottom of the pier foundations. The large foundations were 26x57 ft. in plan, and as all the excavation was done before the piles were driven and the pier foundations were from 10 to 16 ft. in depth and in most cases sheeted and braced, it was out of the question to lower the piledriver into the hole. Therefore, 24-in. I-beams, 40 ft. long, were placed across the hole to support the piledriver. It was found that about as good progress could be made working from the I-beams as would have been obtained on the ground itself. A row of piles was also driven about 7 ft. c. to c., under the front edge of the retaining walls of the north end, but no piles were placed under the south walls.

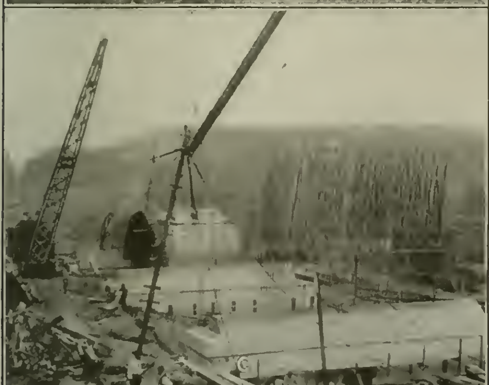
All piles were Raymond cast-in-place concrete piles and the core was driven with a steam hammer. Seven blows to the last inch gave them sufficient penetration to withstand the test required by the city, which was that one pile in each pier be selected and loaded up to 60 tons with an allowed settlement of $\frac{3}{8}$ in.* On account of the irregularity of the underlying gravel bottom into which the piles were driven, their length varied from 12 to 27 ft., averaging 17 ft.

Concrete

Piles were first driven on the south approach, then the piledriver was moved over to the north approach; but on account of waiting to make the tests it was nearly five weeks from the time the selected pile was driven until the concrete could be placed in the piers. Concrete was placed in wood and steel forms in lifts of about 300 cu. yd. at a time, that being about the average amount of concrete placed in ten hours with a $\frac{3}{4}$-cu.yd. mixer. As fast as two adjacent piers were concreted up to the spring line the centers for the arches were set up, and at the same time work was started on the retaining-walls and carried on so that both would be completed at the same time.

The arch rings were concreted in three 18-ft. wide sec-





Construction Views of Approaches to North Side Point Bridge, Pittsburgh, Penn.

A—Steel spans across Allegheny River, with mixing plant. B—Steel forms on 38-ft. counterfort wall. C—Piers on north approach, showing reinforcing. D—Setting steel ribs for arch centers.

*In testing a pile, a circular steel plate was first grouted on the pile head, and on this was placed a latticed steel column which carried balanced on its top the loading timber on which rested the tank framework. Side posts were also provided for carrying the tank framework through the medium of wedges until a balance was attained. When the wedges were struck, the tank, containing the desired load of water, rested on the pile under test. See also article describing these tests, in "Engineering News," Aug. 6, 1914, p. 310.

forms. Concrete was first placed at the spring line and kept at the same height on both sides of the arch until it met at the crown. The flow was regulated by a damper on the chute, at the center of the arch; one batch from the mixer was allowed to flow to one side while the next one went to the other. A section containing 270 cu.yd. could be filled in from 8 to 12 hr.

In all cases the center section of the arch ring was concreted first and allowed to set from 15 to 20 days, depending on the weather, before the center was removed.

Work on the north approach was carried on in the same manner as the south end, walls and arches were worked together.

Forms—The forms on this work were something of a problem, as only two pairs of arches out of eight were identical, and the wall forms had to be constantly changed from one type to another. After a careful study it was decided to use sectional steel forms for the walls, and steel ribs covered with 4x4 lagging for the arches. The steel wall forms were built up in place for the first section and then moved ahead by the locomotive crane in sections 15 to 20 ft. wide and the full height of the wall, which varied from 10 to 26 ft. Some of these sections weighed about four tons, but no trouble was experienced in placing them with the crane. The only difficulty encountered was changing plates to fit around braces in the deep ditches. This sometimes required much time; but on gravity walls and walls where there was no bracing to contend with, the steel forms worked very successfully.

The arch forms were made up with four steel ribs for each 18-ft. section, spaced 5 ft. 6 in. c. to c., and bolted together with angle iron and cross-braced with rods having turnbuckles for adjustment. Planks, 2x12 in. in cross-section, were bolted on each rib and to this was nailed the 4x4 Y. P. lagging which was surfaced on four sides and beveled 1/4 in. on two sides so that the top edge would fit tight. The rim forms were made from 2x12 surfaced yellow pine and were wired down to the lagging.

Reinforcement

Because of its varied lengths and sizes, the reinforcing steel was ordered in 10-ft. lengths and cut on the job as desired, with hand-operated cutters of German manufacture. These cutters were found superior to anything in that line on the market in the United States. The steel reinforcing for the counters in the counterfort walls was made on the ground and hoisted into place by the crane and the forms placed around it. The other steel was placed after the forms were set.

The arch steel was bolted with hookbolts to transverse lattice struts, set radial to the arch, and spaced about 9 ft. 6 in. c. to c. By this means the steel was held rigid.

Diamond bars were used throughout the job, of the same cross-sectional area as square bars of the same weight, but much easier to handle and bend.

Personnel

The work was designed under the direction of N. S. Sprague, Superintendent of the Bureau of Engineering, Pittsburgh; T. J. Wilkerson, Division Engineer of Bridges. Booth & Flinn, Ltd., Pittsburgh, are the general contractors, for whom M. J. Feeney is General Superintendent and the writer Constructing Engineer in charge of the work. The Raymond Concrete Pile Co. were subcontractors for the piles, while the Blaw Steel Construction Co. furnished the steel forms and arch centers.

Tearing Out a Reinforced-Concrete Subway

In preparing to connect the present eastern terminal of the old Steinway tunnel under the East River at New York City with the new line of rapid-transit subways extending into the borough of Queens, it was necessary to remove approximately 800 cu.yd. of reinforced-concrete subway structure. The accompanying view, from a photograph taken within the past month, shows the work of demolition practically completed. The structure re-

East Terminal Steinway Tunnel, Long Island City, Before the New Subway Connection

moved consisted of a 14-in. roof slab supported on sidewalls and intermediate columns, all reinforced and tied together. The old terminal station was completed in 1907, so that the concrete had reached a final set; in fact the monolithic character of the whole structure made its destruction most difficult.

Several methods of razing were tried before a successful one was hit upon. First, holes were drilled for blasting in the center of the sidewalls, but when fired the reinforcing rods held the walls and roof as firmly as before. Next, the roof was attacked with a 2300-lb. piledriver hammer swung from a derrick; this made practically no impression. Finally, it was decided to begin at the joints of the sidewalls and floor where the rods crossed each other at right angles. These walls were 2 ft. thick at the top and reinforced with two vertical rows of $1\frac{1}{4}$-in. rods.

In the horizontal line of the joint between sidewalls and floor, holes were driven downward at an angle of 45°, spaced 18 in. apart. On firing these holes the bond at the joint was broken. The roof was similarly drilled from the outside and broken down by blasting. This plan resulted satisfactorily, and sections of the sidewall and roof were successively tumbled into the tunnel where they were broken up by drilling and firing 6-in. holes.

The piers and columns supporting the roof were blasted out by drilling holes on one side, inclined down about 45°. When fired these charges had a twisting force which cut the columns from off the piers. Two of these piers will be seen in the view, a ladder standing on one. They were originally intended to carry, in addition to the roof of the subway, a six-story office building.

The Degnon Contracting Co. has the contract for the removal of the existing station and loop, and, in addition, will construct a new station a short distance east of the old site, and an elevated structure to the plaza of the Queensboro Bridge.

Fig. 1. Guy Piledriver, Amsterdam, Holland

A Dutch Piledriver

The accompanying views show a piledriver of remarkable design in action in Amsterdam, Holland. In Fig. 2, note how loosely the ram hangs between the leads.

William Hoeker, of 24 Plaats, The Hague, Holland, who furnished the views, says that the Building Department of Amsterdam restricts the loading on an average wood pile (0.24 m. or 9.36 in. diameter) to about 10 tons. He says that few pile failures occur, but that occasionally long piles are driven until they penetrate the hardpan under the mud topsoil, in which case the foundation sinks.

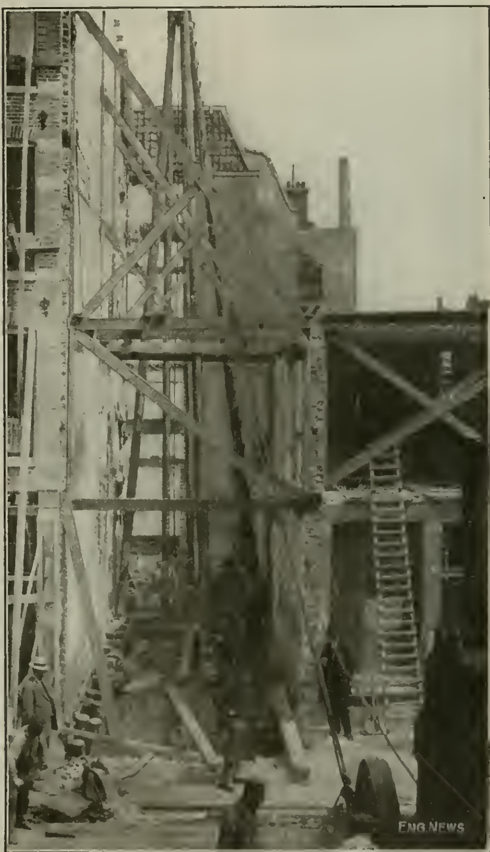


Fig. 2. The Piledriver Working in Restricted Quarters

Points on Waterproofing—In answer to a query as to the preference for brick laid in asphalt mastic over membrane waterproofing on the New York subway work, F. Lavis gives the following explanation: "The brick in mastic is usually used where greater security is required than is afforded by the felt or fabric waterproofing, and where the necessity of making the best possible provision against failure warrants the additional expense. The felt has been known to disintegrate under the action of groundwater strongly impregnated with illuminating gas drip, which does not affect the mastic. Usually the brick in mastic is used below the level of M.H.W. where pressures have to be resisted and where a failure of the waterproofing might mean very serious trouble. The mastic is used hot."

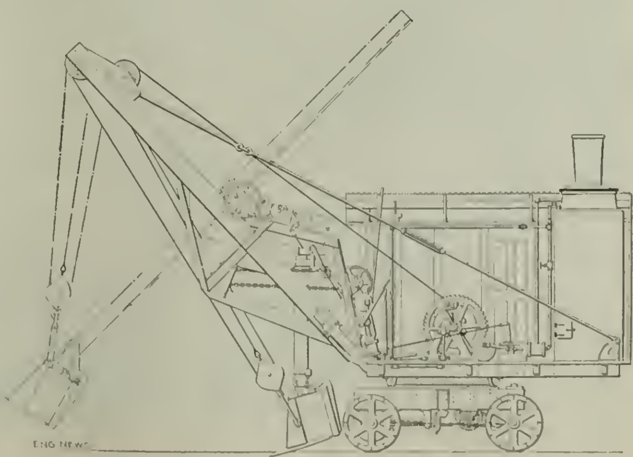
the bottom of which (and in the foreground of the view) runs a railroad on which the concrete material can be brought in. The material is stored alongside the track, mixed there and brought on the runway in the foreground and wheeled

POURING CONCRETE IN ARCH RIBS OF SHEPHERDS DELL BRIDGE, OREGON

in barrows over the runway, to be dumped into the cars which run directly under the platform on the left. These cars are then pulled by cables up the inclined track to the base of the tower, elevated to the top and spouted through the chutes to the proper location on the bridge. The contractor for the bridge is the Pacific Bridge Co., and the engineering is in charge of the State Highway Department.

A Combination Boom for Steam Shovels—A boom has been designed by the Thew Automatic Shovel Co., of Lorain, Ohio, with which the shipper-shaft motion commonly used on steam shovels can be used, as well as the horizontal crowding motion employed on this concern's machines for many years. The latter is well adapted for shallow cuts and surface work; the former for trenches and where long dumping radius or high clearance lift is needed. The two mechanisms are independent and noninterfering. With the long-handled dipper in use, the short dipper arm is chained to the boom; when the short-handled dipper is wanted the long arm is removed. Change of engine, steam connections and dipper handles takes about three hours. The long handle is of wood, 8x8 in., plate armored and fitted with racks on the under side. Any length up to 24 ft. can be used, although where a clearance lift of over 10 ft. is required, a part of the cab roof must be removed. The striking peculiarity of the combination boom is the diamond frame necessary to accommodate the engine in two positions.



NEW THEW SHOVEL BOOM

Getting Radiators Out of the Way—At the plant recently completed for the Hendee Manufacturing Co., Springfield, Mass., the placing of the radiators offered quite a problem. No wall space was available, and it was finally decided to put the radiators on the interior columns. These are built-up I-columns, as shown in the accompanying illustration. A standard wall radiator, manufactured by the H. B. Smith Co., of Westfield, Mass., was used. These are in seven sections, five pipes per section The radiators were held in place at the bottom by a heavy bracket. The pipe connections were made at the bottom of the stack of radiators.

RADIATORS INSTALLED ON I-COLUMNS IN A SPRINGFIELD SHOP

New York Experience With Winter Surveys for Highway Improvement—In the past many surveys of roads have been made in the winter when the ground was covered with snow and it was difficult or impossible to judge with any approach to accuracy of the soil conditions below. Obviously, too, surveys made under such conditions would be inaccurate. We are now trying to make our surveys in summer and fall in order that these sources of errors and troubles may be avoided. One of the most frequent excuses given for the making of supplemental agreements has been that these surveys were made in the winter when subsoil conditions could not be observed and especially drainage problems anticipated. With surveys made when the ground is bare and when the soil and drainage may be freely and carefully studied, we expect to secure more perfect plans that may be carried out and roads built with much fewer changes in contracts. More attention is being given to the preparation of these plans in detail and greater care is exercised in supervising plans presented by division engineers to headquarters to the end that they may be complete and specific, more quickly read and less liable to misunderstanding.—Geo. A. Ricker, First Deputy State Highway Commissioner, New York, in "New York Highway News" for September, 1914.

Inexpensive Printed Specifications of Pocket Size—It [illegible] a great [illegible] use of [illegible] in the [illegible] of [illegible] specifications [illegible] the [illegible] made [illegible] it almost impossible to [illegible] of the [illegible] consideration [illegible] saving [illegible] by a [illegible] for newspapers, and the specifications [illegible] in the form of a book with pages [illegible] the resulting pamphlet is [illegible] without folding and the pages [illegible] for [illegible] ordinary notes of [illegible]—[illegible] C. Sherrod, Boston, Mass.

Street Crossing Traffic Signals, Cleveland, Ohio—A street traffic [illegible] system was installed last August at the intersection of Euclid Ave. and East 105th St., Cleveland, Ohio, which has given excellent service ever since. The system is [illegible] the same as a railway crossing, although [illegible] in the apparatus itself to suit street conditions. It is estimated that traffic can be handled [illegible] faster than by a traffic policeman in the street.

[illegible] signal lights are placed on the right hand side of each street facing oncoming vehicles. A red light signifies "stop," and green "proceed." The switch controlling the lights is operated by a traffic officer in the booth to the left, in the accompanying illustration. The switch is so interlocked that it is impossible to give conflicting signals. The sides of the booth are glass, so that the officer may see out on all sides. The red light signal is shown on the [illegible] of the crossing street and the green light on the far corner, instead of having both lights on the same pole as in railway practice.

A [illegible] signaling instrument, connected to the fire department headquarters, is located in the officer's booth so that he is warned when it is necessary to clear the crossing for the passage of fire apparatus. On these occasions the officer [illegible] an emergency [illegible] which [illegible] an alarm bell and shows red lights on all corners. He is then free to leave his booth and give his attention to the street. Similar systems using semaphore signals have been tried in other cities, notably in Philadelphia.

The Cleveland installation was made by the American Traffic Signal Co., of Cleveland.

The Crown of Bituminous Macadam Roads in Massachusetts has been reduced to ¼ in. to 1 ft. in accordance with English practice, which is now almost universally ⅛ in. to ⅛ in. or ¼ in. to 1 ft. This is a reduction in crown of [illegible] in. from the standard sections for bituminous macadam roads referred to in the article on Massachusetts highway work in "Engineering News" of Nov. 26, and is a [illegible] for highways in this country. It compares with crowns of [illegible] in. per ft. width for ordinary macadam.

Editorials

A Constructive Policy for Public-Service Corporations

Among the notable papers presented at the recent conference of Mayors in Philadelphia was one by Charles Day, of the engineering firm of Day & Zimmerman, with the suggestive title printed above.

Mr. Day urges that the companies should drop their attitude of antagonism toward the regulating commissions, should frankly recognize that public regulation is here to stay and should heartily coöperate with the public service commissions and city authorities. Mr. Day speaks with full appreciation of the companies' point of view, since his firm controls a large central-station plant in Pennsylvania.

At the present time the attitude of most public-service corporations and their officers toward some of the restrictive measures of the public-service commissions may be fairly described as one of rebellious protest. There is without doubt ample ground on which to base this protest; but Mr. Day declares that instead of hoping for a better state of affairs through the amendment of faulty laws or through a better appreciation of their duties and of the rights of the companies on the part of public-service commissioners, the responsibility rests squarely upon the corporations themselves. Until they come forward to coöperate with the commissions, by furnishing them the basic data on which to ascertain cost of service, bitter contention over rates is bound to continue.

The companies distributing electric current, for example, have almost universally adopted a sliding scale of rates giving a far lower rate to the large users of current, and particularly to the user who takes current at a time when a large part of the station equipment would otherwise be idle, than to the ordinary customer. Mr. Day urges that the small consumers of electric current should likewise have rates adjusted to their needs. Analysis of the operating cost of electric systems shows that a very large part of this cost varies very little with increase in current consumption.

Here, for example, is a small consumer using 10 kw.-hr. of electricity per month from which the station must receive a revenue of $1.20 to cover the fair cost of supplying the current with a reasonable margin of profit. If the consumer pays a flat rate per kilowatt-hour, the straight charge would be 12c. per kw. Analysis of the station-operating cost, however, would very likely show that two-thirds of this amount, or about 81c., would represent the expense incurred in such charges as bookkeeping, reading meters, rendering bills, fixed charges on equipment, distribution, etc., which do not vary with increase in consumption. If, therefore, the consumer were required to pay a fixed charge of 81c. per month whether he used much current or little, and in addition a charge of 3c. per kw.-hr. for current used, the company would receive the same revenue as before, $1.20, but the consumer would have every incentive to increase his use of current; for example, by the use of appliances for electric heating, which now very generally involves prohibitory expense.

Such an adjustment of rates to small consumers, moreover, would go a great way toward producing a better feeling of the public toward the companies. At present it is very difficult to make the average consumer believe that a company is justified in charging him 10c. for current which it cost the company often less than half a cent to produce at the power station.

The New York Alien Labor Law and the Subway Contracts

Probably neither the contractors, the labor leaders nor the Public Service Commission know what is to be the outcome of the controversy over the enforcement of the Alien Labor Law on the New York subway contracts. It is fairly certain, however, that none of these three parties really desires to tie up indefinitely these contracts on which so many thousand men are now actively at work.

The Alien Labor Law makes it mandatory upon the Commission to annul any contract on which it is shown that the contractor has employed alien labor. The labor union which has petitioned for such an annulment of one of the contracts withdrew its complaint on Nov. 28, and it is claimed that this relieves the Commission of the necessity of deciding the case. According to the strict letter of the law, it might indeed be said that it is incumbent upon the Commission to annul any contract on which alien labor is employed as soon as the fact of such employment is established.

It is equally incumbent upon the Commission, however, to observe the spirit of the law and protect the great public interests committed to its care. To cancel the existing subway contracts at the present time would mean a loss of many millions to the city in the delay involved and in the difficulty and complications attendant upon the adjustment with the contractors and the reletting of the work.

Engineers well know the serious difficulties encountered when, through the failure of a contractor when his work is partially completed, the reletting of the work or its continuance by force account becomes necessary. There is trouble enough for engineers and all parties concerned when one or two of the contractors on a great engineering work fail in their task and readjustment is necessary. But the labor thrown upon the engineering force in case a wholesale annulment of existing contracts were attempted would be enough to break down the whole organization.

It is claimed that the Alien Labor Law might be declared unconstitutional as being contrary to existing treaties between the United States and foreign countries in which the citizens of those countries are promised equal rights and protection with American citizens. Certainly, the matter should be settled one way or the other by an appeal to the highest court. It is a serious mistake and

[illegible] such an act as the New York Alien Labor Law remain on the statute books and be ignored. There is always a chance that such laws, after long remaining a dead letter, may suddenly be brought forward to make serious trouble for [illegible] who has merely followed the general custom in his line of business.

A Favorable Time for Construction Work

The amazingly low prices which are being quoted on structural steel at the present time are worthy of notice, especially since there is some reason to believe that prices in this field are about at the bottom and that a considerable advance may be looked for at no distant day. Contracts have recently been awarded by the Panama Canal to the United States Steel Products Co. for about 9,000,000 lb. of structural steel required in the construction of the wharves at the Cristobal coaling plant. The price for the material delivered at Colon is 1.96½c. per pound.

When it is considered that this material has to be fabricated at the shops, carried by rail 400 miles to tidewater, loaded on board a steamship and transported 2000 miles to the Isthmus of Panama, with the cost of marine insurance added to that of freight, and further that the material is subjected to an extremely rigid government inspection, it is evident that the structural-steel business at present is being carried on with an extremely narrow margin of profit.

It is, of course, true also that other engineering materials are being sold at phenomenally low prices. The Metropolitan Water and Sewerage Commission, of Massachusetts, recently purchased 1000 tons of cast-iron pipe at $19.60 per ton, delivered at Boston.

Such prices as these make it a most advantageous time to undertake new construction work, wherever such work can be successfully financed.

Not only are prices of all construction materials extremely low, but on contract work competition is very sharp. Contracts were recently advertised in ENGINEERING NEWS for the construction of a system of water supply and sewerage for a village of 3000 inhabitants in the Hudson valley. In ordinary times such a small contract [illegible] only a limited number of bidders, mostly residents of the locality. In this bidding, however, [illegible] contractors submitted bids for the construction of the waterworks, at prices ranging from $31,[illegible] to $[illegible]. These bidders came from [illegible] different states. For the construction of the sewerage system there were [illegible] different bidders, their prices ranging from $[illegible] to $[illegible]. These bidders also covered a similarly wide geographical range.

The labor market is extremely favorable to construction, whether work is done by contract or by day's labor. [illegible] a fixed rate of wages, [illegible] and [illegible] a good quality of [illegible] that are difficult to [illegible] in ordinary times.

An additional reason for prosecuting public works at the present time is [illegible] in some degree at least, to solve the serious matter of unemployment. In [illegible] are out of work [illegible] public [illegible] it is certainly better to give a man money in the shape of wages, so that the public gets a return for the money in work performed, than to dole out a third, possibly, of that amount in the form of poor relief, from which the public gets no return whatever and the recipient of the relief is pauperized.

At Pittsburgh, the City Council on Nov. 23 appropriated $80,000 to proceed with extensive street improvements in order to furnish work for some of the unemployed in that city.

The Maximum Rate of Safe Retardation for Passenger Cars and Elevators

Collapsible, shock-absorbing vestibules as a means of safeguarding the lives of passengers in steel cars in the event of a train collision are discussed in the report of the Committee on Rails and Equipment, presented at the recent meeting of the National Association of State Railway Commissions. It is obvious that such an arrangement would be of comparatively small benefit to the passengers in cars at the end where the collision occurred, while at the opposite end of a long train the gradual stoppage, due to the collapsing under resistance of the vestibules between the ends of the cars, would doubtless cause the stop to be very easy.

The committee deemed it best to inquire what was the maximum safe rate of retardation which passengers could endure without danger of serious injury. Inquiries were made of Thomas E. Brown, Consulting Engineer of the Otis Elevator Co., and the following reply from Mr. Brown gives very interesting data as to the possible retardation which human beings can endure in falling elevators.

> Our experiments and experience have been entirely with passengers traveling vertically and standing on their feet, where the effects of retardation have been along the axis of the body, the stress being principally on the ankles and spine. Under these conditions I and some of my associates have been subjected to retardations as high as [illegible] ft. per sec. per sec. Such a retardation can be sustained without injury, and, in fact, without much discomfort. The stress on the ankles is quite [illegible].
>
> A man lying flat on the floor of an elevator car would, without doubt, withstand at least double this retardation without serious [illegible].
>
> In [illegible] practice it is customary to allow for retardations of five or even six times that of gravity, i.e., retardations up to nearly [illegible] ft. per sec. per sec., and it is considered that even this high retardation will not be [illegible] to life. Naturally but few actual tests with human beings at such high retardations have been made, but there are several instances on record where it has been sustained without any serious injury. [illegible] there have been cases [illegible] where serious injuries and even death [illegible], but there is reason to believe that in these cases, through faulty design, the retardations were [illegible] in excess of five or six times that of gravity.
>
> [illegible] the physical condition and especially the [illegible] of the subject when undergoing such a [illegible] must be taken into consideration; thus a man in a sleeping berth with feet toward the engine would not be likely to be [illegible] and perhaps not even injured by a retardation of [illegible] to [illegible] ft. per sec. per sec., whereas it is doubtful whether a [illegible] under the same conditions might not [illegible].
>
> My own opinion is, that if the railroad car [illegible] the [illegible] is sufficiently strong not to be destroyed or [illegible] by the [illegible], the passengers, with the exception of some as may be in an [illegible] position, are not [illegible] to sustain other than minor injuries with any stop liable to occur in a derailment or even a collision. In other words, [illegible] the conditions expressed in your letter, viz.: "The [illegible] all dangers from passengers getting into contact

with the car," I am of the opinion that the passengers can stand any retardation that the car itself can stand.

In this connection I would suggest careful consideration of the fastening of the seats to the floor of passenger cars.

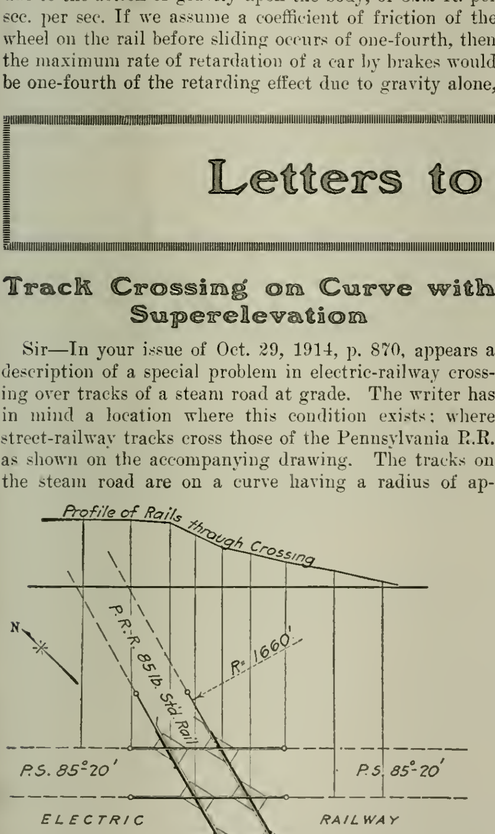
It will be evident, of course, that the retardations mentioned by Mr. Brown are many times what would be practicable in stopping railway cars by the use of brakes applied to the wheels. The limit of retardation of a car by the use of brakes occurs when the wheels slide on the rail. If a body moving at uniform speed is acted upon by a retarding force equal to its own weight, the rate of retardation would be equal to the rate of acceleration due to the action of gravity upon the body, or 32.2 ft. per sec. per sec. If we assume a coefficient of friction of the wheel on the rail before sliding occurs of one-fourth, then the maximum rate of retardation of a car by brakes would be one-fourth of the retarding effect due to gravity alone, or 8 ft. per sec. per sec. In practice it has been found that about half this, or 4 ft. per sec. per sec. is about the maximum rate of retardation by brakes that is permissible without causing discomfort to seated passengers.

The figures given by Mr. Brown for the rate of retardation which passengers in a vertical elevator can endure without danger when it is stopped by a safety clutch or air cushion seem surprisingly high. A rate of retardation of 32.2 ft. per sec. per sec. would have the effect while the retardation lasts of substantially doubling the weight supported by the person's feet and ankles and—what is less serious—that supported by the knees. With a retardation of 72 ft. per sec. per sec., therefore, the feet and ankles of a person weighing 200 lb. would have to support a weight of nearly 650 lb. for the brief period during which the retardation acts.

Letters to the Editor

Track Crossing on Curve with Superelevation

Sir—In your issue of Oct. 29, 1914, p. 870, appears a description of a special problem in electric-railway crossing over tracks of a steam road at grade. The writer has in mind a location where this condition exists; where street-railway tracks cross those of the Pennsylvania R.R. as shown on the accompanying drawing. The tracks on the steam road are on a curve having a radius of approximately 1660 ft. to the inside rail, while those of the street railway are built on a tangent. However, the grade of the street falls away sharply on one side of the steam road. The two profiles show how the rails of the street-railway tracks had to be kinked in order to make the crossing. The gage of the street railway is 5 ft., while the steam road is standard gage.



Plan and Profile of Street Railway Tracks at Grade Crossing of Steam Railway on Curve

The crossing is of the three-rail type and was built in 1912 by the Pennsylvania Steel Co. It is constructed of Pennsylvania R.R. standard 100-lb. rails, the main steam running and bearing rails being of rolled manard-manganese steel. The other rails are of openhearth steel. All intersections are provided with plates fastened to the rails with wrought-iron clips. The fillers are of rolled steel, and the crossing was provided with cast-steel compromise joints at all the external joints.

The connecting rail sections are as shown on the plan. Mayari steel, heat-treated bolts, having an ultimate strength of not less than 105,000 lb., and an elastic limit of not less than 80,000 lb. per sq.in., were used in the crossing, and they were required to bend cold on themselves through 180° without fracture on the outside of the bent portion. This crossing is still in service.

H. G.

Newark, N. J., Nov. 14, 1914.

Practicing Engineers and Industrial Education

Sir—Your readers ought to realize better that engineers employed in all kinds of manufacturing establishments have an unusual opportunity for coöperating and even leading in the various forms of industrial education now coming forward. For instance, in the high school of Passaic, N. J., is an industrial course organized on a half-time basis, somewhat after the Fitchburg plan. The efficiency engineer and the textile engineer from one of the largest textile mills are giving valuable aid in developing the work. These engineers give lectures in the coöperative course on factory costs and upkeep, factory layouts,

and other [illegible] technical topics with special applications [illegible]. They also give instruction to the boys in the technical phases of the work. Foremen of the various [illegible] departments give the instructions in practical operations. By this cooperation with the regular instructors of the school, a thoroughly practical course is guaranteed. Waste of time is avoided. The interests of the boys in the technical aspects of the work are stimulated and economically directed. School work and factory work are [illegible].

In developing cooperative school plans for part-time apprentices, there is a great need for men who actually know both the needs of the factory and the possibilities of the school. School men, even including many of those responsible for industrial schools or courses, know very little about actual factory needs in most cases. They have neither the knowledge nor the experience to make school courses which will supplement the factory work and give the boys what they most need. On the other hand, factory managers, superintendents, and foremen are recruited largely from the ranks of workers, promoted on merit shown for definite lines of work. Many of them know little of school possibilities. Many are even distrustful and skeptical of schools because they know that the schools of the past have been too academic and impractical.

The engineer, however, knows enough of both school and factory to show how they may help each other. He is a practical man and he has had school experience extending through elementary, high, and college grades. In looking back over his school life, he probably sees how much of the work that he was required to do in elementary and high school was really time wasted. He could devise work now on the basis of his factory experience that would have been altogether more worth while than that which he forgot as promptly as he learned it because he never has had any use for it.

The engineer realizes how relatively little of algebra, geometry and trigonometry the ordinary shop man uses, how little of the long, academic courses usually given in mechanical drawing are needed, and how needlessly foreign are the abstract statements and formulas of physics and mechanics to the concrete problems of the workman in foundry, forge room or machine shop. He knows that, in a factory employing a thousand men, the number whose work includes the responsibilities requiring all of this technical knowledge will probably not be over a dozen. What he recognizes is that all of these workers need a little practical knowledge of a few relatively simple parts from all of these fields. They need to know thoroughly, and with a full understanding of their meaning, a few facts and principles in shop mathematics. They should know how to make, and must know, how to read drawings and prints. They should be able to apply a few of the simpler principles of physics and mechanics to their use of tools and machines. All of this knowledge might properly be called mechanical and industrial intelligence. The workman should not only be able to do [illegible] with [illegible] skill but with an understanding of the meaning and reason of it.

Now the [illegible] man with his courses in mathematics, drawing and science will not be able to give this kind of intelligence without a prodigious waste of time. He does not know what to [illegible] or what to omit. The [illegible] cannot give this intelligence. The only hope for the apprentice under the present complexity of factory work is a school plan of some kind in which the school work and the shop work will interrelate at every point. The shop work must give the reason for the school work, the school work must make the shop work meaningful and intelligent. Both going along together will make for an efficiency in the apprentice and a progress in his work which will be compensation equally to him and his employer far beyond the loss of working time given to school purposes.

The engineer has the point of vantage from which to give a great deal of much-needed advice and direction to this cooperative work. He can help to organize and direct the work in mathematics and drawing which will fit in with shop needs. He can point out the parts of physics, mechanics and chemistry which will give the boy that information and that grasp of those principles which will make him an intelligent workman rather than a mere part of the factory's automatic machinery. For the practicing engineer in many manufacturing plants, there is the opportunity for giving substantial and needed aid in building up a more efficient form of common-school education which is necessary to dissipate the frequent charges that our school system is not designed for those multitudes whom we compel to support it. The writer hopes that this statement of the opportunity will lead more engineers to lend their aid.

FREDERICK G. BONSER.

Director Industrial Arts, Teachers College, Columbia University.

New York, Oct. 24, 1914.

The Herschel Fall Increaser and the Ejector Flow Increaser

Sir—On p. 961 (Nov. 12, 1914) of ENGINEERING NEWS, someone describing the power house built next the U. S. dam between St. Paul and Minneapolis, says it is fitted with "fall increasers (Herschel style)."

This is a hard indictment for the invention made by me, which I named the fall increaser, and hard on my interests in it, after spending thousands of dollars to test it at the Holyoke testing flume. The thing shown as having been built on the Mississippi is worthless as a fall increaser, as I can show by experiments made with it elsewhere, while the fall increaser properly so called would generate power at a power house situated as shown in the drawings referred to, and having "backwater" say 30 or more days in the year, at a cost so low that it would not pay to burn fuel to generate the same power in the auxiliary heat-engine plant needed to bridge over the low-water period of the year.

It is adding insult to injury to call this sluiceway built on the Mississippi by my name, not only to me but also to the true fall increaser, for everybody can see how the inevitable failure of the inefficient fake fall increaser is liable to smirch the reputation of the fall increaser that rightly bears that name.

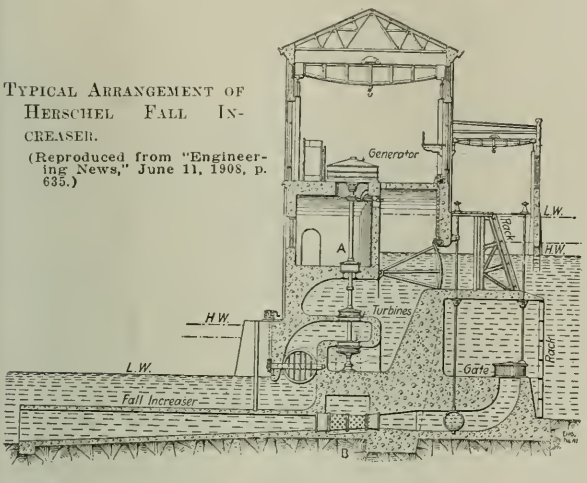
I am sorry to add that this is the third time since the invention of the fall increaser that this same thing has occurred, at Warren, Ohio, at Eldora, Iowa, and now on the Mississippi.

CLEMENS HERSCHEL.

2 Wall St., New York, Nov. 14, 1914.

[The above letter was submitted for comment to Gardner S. Williams, consulting engineer on the power plant of Lock and Dam No. 1 project near Minneapolis. In his comment, which follows, Mr. Williams refers to the auxiliary sluice which opens into the draft tube as an *ejector flow increaser.* The use of the words *fall in-*

TYPICAL ARRANGEMENT OF HERSCHEL FALL INCREASER.
(Reproduced from "Engineering News," June 11, 1908, p. 635.)



creaser and *Herschel style* in the original article is to be charged to the editor.]

Sir—Copy of Mr. Herschel's letter relative to the ejector flow increaser installed upon my recommendation in the power plant at Lock and Dam No. 1 of the Mississippi River Improvement is at hand Mr. Herschel's position is entirely justified. In his fall increaser he has made use very effectively of the principle of the Venturi tube and has produced a device which the writer believes will do all he has claimed for it. The other device depends upon the principle of the ejector and cannot be expected to produce as great effects. It, however, will do somewhat better than Mr. Herschel's letter indicates, and, as in the case in question it was no more expensive to construct it than to omit it. the installation seems amply justified.

GARDNER S. WILLIAMS.

Ann Arbor, Mich., Nov. 21, 1914.

High-Alloy Steels for Bridges have been discussed at some length by J. A. L. Waddell in a paper presented before the American Society of Civil Engineers. In closing the discussion on this paper, in the "Proceedings" of the Society for October, 1914, Mr. Waddell gives the following conclusions:

1. Titanium as a scavenger of carbon steel promises good and useful results at exceedingly low cost. Although it does not increase greatly the elastic limit or the ultimate strength of the metal, it makes it much more uniform and reliable. On this account it should be used in a few cases on bridgework; and then, if it be found satisfactory, its adoption should be made obligatory by railway companies and other builders of carbon-steel bridges.

2. There appear to be great possibilities in the use of aluminum as an alloy for bridge steel. But, very few experiments in aluminum steels have yet been made; hence, the possibilities are more or less hypothetical.

3. The possibility of obtaining a good, high-alloy steel for bridges by the use of vanadium appears to be a settled fact. But the highest elastic limit and ultimate strength which can be obtained on a commercial basis by the use of that element cannot be determined without elaborate and exhaustive experiments.

Water-Works Service Pipes

No problem in water-works operation, apparently, is of greater interest to water-works officials generally than the selection of the kind of service pipe and the method of connecting mains and services. Some points brought out in the discussion of these subjects at the November meeting of the New England Water Works Association are given herewith.

BROOKLINE PRACTICE—F. F. Forbes, superintendent of the water-works of Brookline, Mass., cited 40 years' experience with cement-lined wrought-iron pipe with no record of trouble from corrosion on straight services, but about 30 instances of corrosion at the curb cock connections.

His department has always used a lead goose-neck connection at the main to allow for settlement in the service pipe or main, which is always liable to follow disturbance of the street for subsurface construction. These goose-necks save many leaks, for several instances have been found where the goose-necks had been straightened out by settlement of the pipe yet the connection remained intact.

Service pipes are laid at a depth of 5½ ft. and no trouble is ever experienced with frozen pipes.

Some lead service pipes are used, but difficulty has been found in getting pipe to stand the high pressure used in Brookline.

In getting around subsurface obstructions, it has been found easy to bend cement-lined service pipe to as short as a 10-ft. radius without damage to the cement lining.

The pipe couplings are lined with cement while fastened to one end of a length of pipe, and the cement lining is afterwards dug out of the thread to insert the added length. The F. O. Norton brand of natural (Rosendale) cement is used, as ordinary portland cement is found to be lacking in elasticity.

The pipe fittings are galvanized-iron. Corrosion of the exterior of the pipe just inside the cellar wall is the commonest source of trouble. In such places and in locations subject to alternate wetting and drying the water department now uses galvanized-iron pipe, cement lined.

MARLBOROUGH EXPERIENCE—Geo. A. Stacey, superintendent of the water-works of Marlborough, Mass., said that two cases of lead poisoning through the use of lead pipe for well water, in the early days of the city's water-works, resulted in such a popular prejudice against lead pipe that cement-lined wrought-iron pipe was subsequently adopted for all service connections. Cement-lined iron pipe was used for eight or ten years, but much trouble was experienced by rusting out at joints. Accordingly, about 15 years ago, the water department quietly returned to the use of lead pipe, and it has been used ever since without the least suspicion of lead poisoning.

HOLYOKE EXPERIENCE—Patrick Gear, superintendent of water-works, of Holyoke, Mass., stated that ordinary iron service pipes had been in use for 40 years in Holyoke. No goose-necks are now used for connections at mains, owing to the difficulty in cleaning the service pipes. At present, galvanized-iron and lead-lined iron pipe are being used.

[illegible]—Instances were cited of long life in [illegible] service pipe, but these were exceptions rather than the rule.

An objection was raised to any kind of iron pipe because of the expansion and contraction, which leads to breaks at the curb cock; but this objection is largely overcome by the use of lead goose-neck connections. On the other hand, the objection to a goose-neck connection is the impossibility of cleaning the entire service from house to main. This has led to taking out all goose-necks in Holyoke, wherever new services are placed or renewals are made.

There is a need and a market for some kind of cheap expansion joint for use at curb cock connections, and a need for an effective small pipe-cleaning apparatus.

Difficulties with cement-lined service pipe are chiefly corrosion at joints and want of elasticity. The couplings must be cement-lined, or in some instances rubberoid and tar have been used successfully for lining. Sometimes lead couplings are used. Cement-lined pipe must always be sawed in two and not cut in a pipe-cutting machine, which destroys the lining in the vicinity of the cut.

Lead service pipe is the prime favorite of water-works men generally because of its freedom from corrosion, expansion and contraction troubles, and the ease with which it is bent and cut to fit any location.

Lead pipe should never be used, of course, where there is any chance of lead poisoning, but this is believed to be rare. Robert S. Weston, consulting engineer, of Boston, Mass., pointed out the extreme difficulty in determining by laboratory tests certainty as to whether water would or would not permanently affect lead pipe. Acid swamp waters are particularly dangerous.

The only real guide in many cases is experience; if lead pipe becomes coated on the interior, it is probably safe to use, but any lead pipe which retains a bright interior surface after extended use is almost sure proof that the water conducted through it has dissolved lead and is dangerous. Much popular prejudice against lead pipe is founded on sentiment rather than real reason, was the general opinion.

In many cities public-service corporations place their subsurface structures in any part of the street they see fit, and as the water main is usually near the middle of the street, the result has often been that these public-service structures have completely blockaded the water main, making straight service pipes impossible. This is a condition to be met by a better organization of city departments and by granting more authority to city officials over public-service corporation construction work.

Reported Settlement of a Tunnel in Soft Ground

A report recently came to our attention that the tunnel of the Michigan Central R.R. under the Detroit River was showing evidences of settlement. As most of our readers will recall, this tunnel is a structure of concrete of rectangular cross-section and was built by floating [illegible] into position and filling in around them with concrete deposited under water. There would seem to be no reason why a tunnel of this type should be more liable to settlement than a circular tube tunnel, such as that under the St. Clair River, which is driven through clay very similar to that in which the Detroit tunnel lies.

We find upon inquiry that some settlement did take place during the construction of the Detroit tunnel before it was opened to traffic, and was found to be due to a small amount of leakage coming through the floor of the tunnel. This had the effect of relieving the hydrostatic pressure on the under side of the tunnel and thereby placed an enormous additional load upon the foundation soil underlying the tunnel. Measures were at once taken to stop the leakage through the tunnel floor, and when this was done the settlement stopped. There has been no ascertainable settlement since the tunnel was opened to the operation of trains; and the small amount of water which seeps into the tunnel is steadily decreasing, due probably to the gradual stoppage of the pores in the concrete by particles of silt.

A System for Long Distance Transmission of Readings of Indicating and Recording Instruments

What is perhaps the most noteworthy development in indicating and recording devices since the invention of the several pressure, temperature, position, and other instruments themselves, is a simple system by which the instrument motion is faithfully reproduced at any desired distance up to 40 or 50 miles.

There has been a persistent demand for apparatus to show, at some point remote, temperatures, pressures,

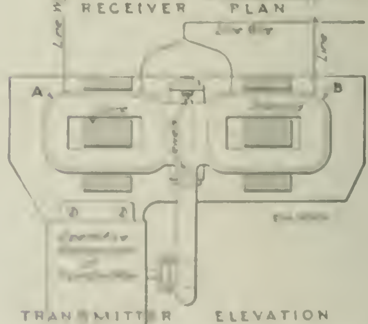


Fig. 1. Diagram of System for Transmitting Movement of Indicating and Recording Instruments

liquid levels, mechanical positions, etc., and various schemes have been put forward with partial success. Pyrometers can be used with the indicator up to 1000 ft. from the work (depending on the types) and millivoltmeters of familiar types have been used with long potential wires to measure distant voltage and current, but

no broadly applicable system for long-distance indicating and recording apparatus has been widely accepted heretofore. A serious limitation of most of the attempted apparatus is its complexity and the step-by-step nature of its operation.

The system described below enjoys the advantages of simplicity of mechanism and steady response. The scheme involved in the commercial apparatus described was worked out and patented a few years ago by J. W. Bard, of the Sangamo Electric Co., and was applied to

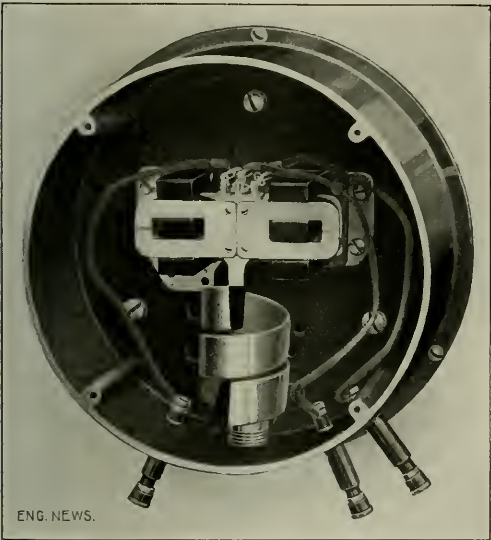

FIG. 2. COMMERCIAL FORM OF TRANSMITTING DEVICE

some Bristol recording instruments for special service. So satisfactory were such services and so frequent the opportunities for extended use, that Prof. Wm. H. Bristol was led to develop the system for use with all sorts of indicators and recorders. Although the system is only now being put on the market, yet over a dozen sets of preliminary apparatus have been in service up to four years, and are reported to be in still satisfactory operation.

The principle of the transmission system is one of induction balance, as may be seen from Fig. 1, which shows the transmitter and receiver (in elevation and sectional plan respectively). Both are similar, and each has a pair of solenoids, balanced on a shaft and hung in jewel bearings so as to swing in a horizontal plane over the ends of laminated iron cores. The transmitter solenoid is swung into some certain position by the arm and link of an operating mechanism which may be, for instance, a series of diaphragms operated by water pressure, etc. The receiver has, instead of such an attachment, a low-friction multiplying arm and link leading to the familiar indicating needle or recorder pen arm.

With the electrical connections as shown in Fig. 1, if the coil *A* of transmitter is caused to swing on and the coil *B* off the iron core, then the inductance of the two coils is changed. That of *A* becomes more and that of *B* less than before, with the result that less current flows from the alternating-current supply circuit through the *A* coils of both transmitter and receiver, than through the *B* side. This causes the *B* coil of the receiver to exert a greater force than the other, so that the moving system is turned until such a position is reached as gives an unequal inductance of its coils, nearly balancing the changed condition in the transmitter coils. Then the current divides between the *A* and *B* circuits inversely according to their inductances until a second shift of the transmitter occurs. The alternating current produces a very slight vibration in the moving systems of both transmitter and receiver, but this is an advantage rather than otherwise, since it reduces any starting friction and makes the system practically "restless." It appears from the diagram (Fig. 1) that the moving systems of transmitter and receiver move in reverse directions as a consequence of the tendency to secure an inductive balance. Where desired, motion in the same direction can be secured by reversing the connections of the *A* and *B* coils.

The mechanism of the present design of transmitter, without an indicating arm, is seen in Fig. 2. Already various combinations of transmitters and receivers are being sought. The most popular form, shown in Fig. 3, comprises a transmitter with indicating needle and a distant recording receiver. By using two or more transmitters and the proper circuits and switches, readings of two or more distant instruments have been easily taken on one receiver.

The service for this system seems limited only by imagination. One of the most common demands is for the distant reporting of reservoir and tank levels, where pressure gages on pipe lines will not give true information because of friction, etc. River-stage data, water, steam, air, and gas flow and pressure, at some inaccessible point, are all items on which current data are frequently required and are satisfactorily furnished by an installation of this

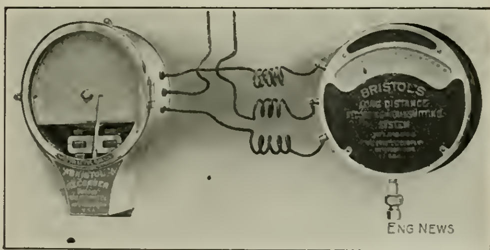

FIG. 3. INDICATING TRANSMITTER AND RECORDING RECEIVER

sort. There is a large untried field of position signal and log work, as on shipboard. Installations have been sought by citrus growers in order that the orchard office may be continually advised and have a record of the weather conditions in the coldest parts of the grove, instead of at present relying on an alarm when the danger point is reached.

The Street Railway System of Guayaquil, Ecuador, is equipped with electric cars having a maximum speed of about seven or eight miles an hour, with tracks zigzagging along the streets without apparent reason for deviating from a straight line. There is also a rival line of street cars drawn by undersized mules. These, a correspondent informs us, "have no difficulty in going as fast as the cars on the electric line."

Engineers from the Contractor's Viewpoint*

By R[illegible] W. S[illegible]†

That complete harmony cannot exist between engineers and contractors, by reason of each in a considerable degree representing opposing interests, is inevitable. The engineering graduate starts with an elevated prejudice against contractors, whom he believes to be, in the main, determined to get the best of engineers, and therefore he is on his guard and purposes not only to take care of himself but to get the best of the contractors.

Contractors dread the "boy engineer" just from college. These young engineers are extremely technical. They expect a literal compliance with every iota of the contract obligations by the contractor.

With rare exceptions, men greatly improve in learning, wisdom and disposition as they grow older. After 20 or 30 years, a man is surprised to find how little he knew when he started his professional or business career. He has grown in riper judgment, and has developed greater patience, discretion and justice toward others. He grows considerate, amiable and kind.

Contractors are largely influenced by their opinions of engineers. The engineer who has a reputation for ability, honesty, fairness and good disposition will attract bidders for any work of which he has charge and the desire to do work under him would be an incentive to reasonably low prices. It is a feature of contracting to "size-up" the engineer with as much accuracy as possible.

In bidding for work, contractors are almost as sensitive as weathervanes. It may be possible to make a profit at a given bid under one engineer and impossible to avoid a loss under some other engineer, with all other conditions similar and the quality and the merits of the work constructed being equally good at the same cost to the owner in each case.

A majority of bids are too high. The highest bid is often twice as much as the lowest even when the lowest is sufficient. Over-anxiety to secure the contract is the commonest cause of low bidding. Low bids are often made to keep a contractor's organization together for future work on which he hopes for better prices.

Contractors who do not care for the contract often bid fairly high on [illegible], without any expectation of securing the contract but merely to avoid a reputation among contractors of being low bidders, and with the bare chance of getting the work at good prices. Excessively high bids are usually the result of lack of knowledge of the value of the work and lack of time to become familiar with it.

If an engineer's preliminary estimate is believed to be too low, it drives away bidders and tends to indifferent, high bidding. Some unscrupulous contractors may be influenced thereby to bid too low. They may secure the work, in which event the engineer has an unpleasant task during construction. There is almost sure to be a disposition on the part of the contractor to save himself from loss and to be thus tempted to slight the quality of the work. Both contractor and engineer are in some degree injured by the work having been done at less than cost.

An engineer who can make reliable preliminary and estimates will find his services in demand by municipalities, corporations and other owners, or if he chooses to practice as a contractor's engineer, he will find his services of great value in that field. Some prominent engineers of my acquaintance would not under any circumstances do engineering work for contractors, confining their services entirely to the owners. I know of other engineers who confine themselves wholly to engineering for contractors and who do a large business as engineering experts for contractors, in litigations.

These two fields of engineering are becoming more and more distinct and it is my opinion that an engineer is wise who makes his choice and adheres strictly either to the one line of practice or to the other.

The contracts and specifications on very large and important works usually are models of perfection. In smaller works, such as may amount to say not over \$200,000, contractors are often confronted with bidding papers, contracts, specifications, plans, etc., which are a disgrace to the engineer who drew them.

There are a few engineers who are sometimes called "specification fiends." They write to many places, where work is advertised, for specifications, etc. They read them eagerly and often clip such paragraphs as catch their fancy—usually those which are harsh, severe and unreasonable from a contractor's standpoint. With these clippings to aid them, they draw up specifications, etc., which often deserve the name of "crazy-quilt" specifications.

Such papers are full of contradictions, useless paragraphs and ambiguities which are almost sure to cause contention and trouble during construction and in the final settlement, or lead to litigation. Such engineers are apt to insert severe conditions such as excessive cash deposits with the bids, unreasonably short time in which to construct the work, excessive per diem liquidated damages for overtime, excessive bonds and sometimes excessive retained percentage where monthly payments are provided. About all they can think of is to make the work undesirable and objectionable to contractors. Such engineers and their work are often avoided by the best class of bidders and the contracts are apt to go to rather undesirable contractors.

*[illegible]

†[illegible]

Sewage Disinfection by Hypochlorite at Providence, R. I., was continued during 1913. The results are summarized in the recently published 1913 annual report of Otis F. Clapp, City Engineer. Of a population of [illegible] about [illegible] are now served by [illegible] miles of combined sewers and there are also 18 miles of storm sewers. The domestic sewage has mixed with it the manufacturing wastes from woolen mills, bleacheries, dye houses, and jewelry factories. The total amount of sewage passing through the plant during 1913 was [illegible] gal. This volume, which included all the storm water, was treated with hypochlorite. The daily flow of sewage ranged from [illegible] to [illegible] million gallons and averaged [illegible] million gallons per day. A total of [illegible] tons of hypochlorite was used. This was at the rate of [illegible] lb. per million gallons. Expressed in terms of available chlorine, hypochlorite was used at the rate of [illegible] parts per million gallons of sewage. [illegible] For earlier use of hypochlorite at the Providence plant, see "Engineering News," Dec. [illegible], 191[illegible] and May [illegible], 1914.

Report on Water-Power Development on the Chicago Drainage Canal

The report of a special commission on the water-power development on the Chicago main drainage canal and the disposal of the energy generated was submitted to the Board of Trustees of the Sanitary District on Nov. 12. This commission is composed as follows: Lyman E. Cooley (Consulting Engineer for the Sanitary District), John Ericson (City Engineer), Wm. Artingstall, H. H. Walker and L. K. Sherman.

The question of water-power development in connection with the drainage canal was considered as early as 1897, but was delayed by litigation and other causes. The District assumed that its general fund was not available for this purpose, but in 1903 a law was passed authorizing a special tax for three years for such development. The tax produced \$3,050,624, but this was exhausted by the end of 1906, and the work was continued by loans (at 4% interest) from the general fund. The plant at Lockport was opened in 1907. The law of 1903 provided specifically for utilizing the water power for the generation of electric current, the use of this current for operating the pumping stations and bridges of the District, and its transmission to municipal corporations within the Sanitary District, the evident intent being that the distribution and retailing of current should be left to these corporations.

The total expenses incident to development, transmission and distribution, up to the end of 1913 amounted to \$6,714,200. Excluding the distribution undertaken, though not originally contemplated, the expenditures were \$5,063,648. In Chicago alone the distribution has amounted to \$1,619,553. It is considered probable that the distribution will be eliminated eventually, in accordance with the original purpose. The present return is barely sufficient to meet current expenses, and unless the rates are increased the District must continue to invest new capital.

The commission considers that the following conditions are necessary for making the water-power enterprise a valuable property: (1) Uniform flow in the drainage canal, with a volume adequate to a sanitary condition and not less than 20,000 min.-ft. for each 100,000 people; (2) increased return on the investment by more favorable rates and increased output (by passing a greater volume of water); (3) modernizing the power plant and thus increasing its efficiency. In addition, various changes in administration and accounting systems are recommended, with the abandonment of all distribution beyond the transmission terminals.

In a separate report, Mr. Cooley deals with the power plant, and states that the present equipment gives a plant of moderate or low efficiency which is costly to maintain and operate. It consists of seven horizontal-shaft units of 6000 hp., with six turbines to each generator. Space is provided for an additional unit. The eight units with 34-ft. head and 80% efficiency would represent 42,650 hp. He advocates new units consisting each of a vertical turbine with an overhead generator, each unit being equivalent to two present units (with their 12 turbines). Such a plant should have an over-all efficiency exceeding 80% under working conditions; this is more than 10% above that called for by the present plant, and still higher than the efficiency realized in practice. His conclusion is that such results call for any betterments than can be made in the plant and in its maintenance and operation, and perhaps would justify a complete modernization of the plant

An Exhibit of Modern Street-Cleaning Apparatus

The first exhibition of devices and machines for municipal street cleaning to be held in this country was very successfully carried out during the week of Nov. 23, under the auspices of the New York City Street Cleaning Department, of which John T. Fetherston is Chief. The exhibits were intended not only for the education of the employees of the department and the general public, but to provide an opportunity for practical tests or demonstrations of unfamiliar apparatus.

The exhibits included brooms, brushes, sweeping machines, flushers and squeegees, snow plows, carts and wagons, and various receptacles for garbage, ashes and rubbish, including special carts and wagons designed to be both dust- and odor-proof. Besides these there was an interesting collection of original posters designed by public-school children as a part of a plan to interest the tenement-house population of the city in keeping the streets and alleys clean and tidy.

The exhibits of street-cleaning apparatus may be divided into four general classes, as follows: (1) Sprinklers, flushers and squeegees; (2) sweepers and sweeping machines; (3) snow plows and scrapers; (4) wagons and receptacles for garbage and refuse. Noticeably absent was an exhibit of vacuum cleaners, which are the most recent development in street-cleaning apparatus.

The accompanying views show some of the more interesting exhibits, excepting those in class (4) above, which will be illustrated in a later issue. The largest exhibitor was Charles Hvass & Co., of New York City, two of whose exhibits, an automobile sprinkler (Fig. 3) and a combined sweeper, sprinkler and scrubber (Fig. 5), attracted attention. The new principle in the sweeper and scrubber is the pushing of the broom instead of pulling it, as is done in other machines. The next largest exhibitor was probably the Studebaker Bros. Manufacturing Co., whose chief exhibits were a constant-pressure flusher (Fig. 2), the pressure being furnished by a centrifugal pump driven by a 30-hp. gasoline engine mounted on the rear of the truck, and a combination sweeper and sprinkler (Fig. 6), which has a spraying device in front of the broom, designed to eliminate dust.

Various types of pick-up sweepers were exhibited, two of which are illustrated. The Hvass exhibit included a small pick-up sweeper. Another type is the "Charlton" sweeper, made by William Dubocq, Brooklyn, N. Y. (Fig. 9), which has had considereable service in New York. The pick-up mechanism in this sweeper is on one side of the rear wheels and the refuse is discharged into cans, which are easily removed from the body of the wagon. The newest type of pick-up sweeper was that exhibited by the Merritt Street Sweeping Machine Co., New York City (Fig. 8). This is a four-wheel, steel-frame vehicle with a rotary broom on either side, set at angles to sweep the dirt into a row under the machine, where a rear broom sweeps the row over a flexible steel shoe to a conveyor, which carries the sweepings up and through a

[illegible] placed on a revolving platform for [illegible] under the chutes.

Snow-plow [illegible] ranged all the way from the old-style [illegible] to the new "Mason" automobile-truck [illegible], made by the Auto Snow Plow Corporation, New York City (Fig. 10). Snow plows of the road-scraper type were exhibited by the Good Roads Machinery Co., Inc., New York City, and the Baker-Barron Co., Inc., New York City (Fig. 11). The newest device in this class was the "ice remover," made by the latter company (Fig. 11). This is a plow and toothed scraper combined on sled runners, and is designed to remove the thin film of ice and snow which makes smooth pavements so slippery in winter.

Various types of motor vehicles for municipal use were exhibited, including a small three-wheel electric tractor for hauling an ordinary rotary-broom sweeper (Fig. 7), made by the Wirt & Knox Manufacturing Co., Philadelphia, and a gasoline-engine electric-power generating unit for melting frozen water-service pipes, etc., made by the General Vehicle Co., New York City. Other types of motor trucks were exhibited by the Commercial Truck Co. of America, Philadelphia, the Ward Motor Vehicle Co., New York, the Lansden Co., Brooklyn, and the Four-Wheel Drive Auto Co., New York City. The exhibits were particularly interesting in showing the wide adaptability of motor trucks and tractors to municipal uses.

Among the more unusual exhibits were models of a snow-melting device by means of a portable boiler and steam kettles, invented and shown by Howard G. Lapsley, Plainfield, N. J., and a model of a machine designed to sprinkle, flush, rake, loosen, sweep, load, dump and level street refuse; it is also designed to carry and distribute road repair materials and oils, and serve as a road scraper and scarifier. This device was exhibited by the Universal Road Repairing & Street Cleaning Co., Philadelphia. Photographs and drawings of a vacuum-cleaning machine were exhibited by the Way-Cleaner Co., Sandusky, Ohio.

NEWS NOTES

A Grain Elevator Burned in Galveston, Tex., belonging to the [illegible] Pacific Co., on Nov. 17. It is reported that the elevator contained about [illegible] bu. of wheat and that the loss is estimated at [illegible].

An Earthquake in Western Greece and the Ionian Islands [illegible]

Falsework of a New Concrete Building Collapsed [illegible]

A Tight-Joint Sewer System [illegible]

The Cumbre Tunnel [illegible]

Miami & Erie Canal Partly Closed—The Miami & Erie Canal is closed to navigation at the present time from Defiance to Middletown, Ohio. This is the result of failure to provide enough money to maintain the canal. Many of the locks are out of condition and nothing has been done in the last two years to restore them. It is thought probable that the next legislature of Ohio will order all parts of the canal thus out of commission and those not used for hydraulic purposes to be drained. The canal is in charge of the State Department of Public Works, John I. Miller, Superintendent.

Sanitary Industrial Surveys by New York City Health Department—The weekly bulletin of the Department of Health, City of New York, for Nov. 11, makes the following announcement:

The Department of Health is prepared to undertake a sanitary survey of any industry, trade or group of manufacturing or mercantile establishments in this city, with a view to appraising existing conditions and in order to show to employers and workers alike what can be accomplished through a system of voluntary hygienic and sanitary control. Through its Bureau of Public Health Education, the department will be glad to assist in formulating sanitary industrial standards and measures for the prevention of occupational diseases. In addition to this, the bureau stands ready to prepare and furnish health leaflets specially designed for workers in any industry, and to supply popular lectures on health and sanitation to such workers, in coöperation with either employers or trade unions.

A New Record in Precise Leveling has been established by John H. Peters, Assistant, U. S. Coast and Geodetic Survey, whose remarkable record of 120 miles in a calendar month was noted in our issue of Oct. 29, 1914, p. 886. This record was broken in October, in the State of Washington, when 148.3 miles of precise level line was established, equivalent to a total number of miles of single line of 327.7. The party worked 21½ days, and the average amount of time devoted to leveling was 6.6 hr. per day. Benchmarks were set for the most part and records checked by the observing party. All the leveling comes within the requirements that the two runnings of a section agree within 4 mm. $\sqrt{}$distance in kilometers.

Construction of New Buildings at Wellesley College, Wellesley, Mass., to permanently replace those destroyed by fire on Mar. 17, is about to begin. A new college hall will be commenced first. It will be U-shaped, with entrances on the north and south sides. On either side will be a smaller dormitory joined to the main building by stone cloisters. Underneath the cloisters and connecting all buildings will be two tunnels—one for the use of tradesmen, the other to house the heating, water, sewer and lighting piping and conduit. All stairways will be inclosed. A temporary frame one-story building was erected in remarkably short time (March 27–Apr. 7), to take the place of the burned college hall, and was described in our issue of May 7, 1914, p. 1018.

Popular Good Roads Enthusiasm in the mud road districts of the Central West apparently knows no bounds. The following item is from the De Kalb, Ill., "Chronicle" of Nov. 11:

Malta had a most enthusiastic celebration yesterday afternoon about 5 o'clock. Anyone in the vicinity might have thought from the number of whistles that were blowing and the fuss that was being made that the entire town was on fire, but such was not the case. Instead, the cause of the hilarity was the fact that the new cement road [illegible] west from Malta for a distance of a mile and a quarter or so had just been finished and the work was done at a few minutes before the blowing of the whistles [illegible].

[illegible]

Survey for the El Paso Union Stockyards at El Paso, Tex. [illegible]

The Employees of Contractors [illegible] the New York [illegible] during the month of November [illegible] at work on [illegible] employed by contractors working on [illegible] trackking, etc., of the

elevated railway system, which work is done directly by the companies. On the 64 sections now under contract, the total contract price is $146,253,000. Contracts in force for third-tracking involve $8,000,000 to $10,000,000 additional on the Manhattan and Bronx lines and $6,000,000 on the Brooklyn lines, making a total of about $162,000,000 of contracts now in force. Bids were opened on Dec. 1 for the construction of a station on the Fourth Ave. subway in Brooklyn, and are to be opened on Dec. 11 for the Broadway subway between 51st and 59th St. Bids for two or three additional sections will probably be advertised before the close of the year.

The Massachusetts Basis for Utility Rates, or the Public Service Commission's idea of fair value, is thus expressed in the Middlesex & Boston Street Railway Co. six-cent fare case:

It is argued by some of the counsel that the present value of the property used by the petitioner is the only amount upon which it can claim to earn a return. * * * It is sufficient here to observe that few words having a fundamental importance in dealing with questions of law and finance have been found more difficult of accurate and generally accepted definition. * * *

In this fairly consistent adherence to sound principle our Massachusetts public utility code is in striking contrast with the loose and haphazard legislation as to capitalization in many other states, which has requently resulted in compelling their regulating commissions to resort to reproduction cost as perhaps the least unsafe basis for determining a fair rate. Accordingly, we rule that under Massachusetts law capital honestly and prudently invested must, under normal conditions be taken as the controlling factor in fixing the basis for computing fair and reasonable rates; that if there is mismanagement causing loss, such loss must be charged against the stockholders legally responsible for the mismanagement; that reproduction cost either with or without depreciation, while it may be considered, is not, under our law, to be taken as the determining basis for reckoning rates.

In the case at hand the company was ordered to raise the fares to 6c. for single rides, nine tickets for 50c., and ten school tickets for 30c.

An Effective Ordinance for Pavement Preservation went into effect in the Borough of Washington, Penn., Nov. 16. Section 1 of the new ordinance provides that no pavement opening shall be made without a special permit, which (Section 2) must specify where the opening is to be made, the number of square yards of pavement to be disturbed, the time such excavations may remain open, and the total charges for the permit granted. Section 3 provides for a charge of $2 per sq.yd. of paved street opened, payable in advance or within 30 days, or secured by a bond. Section 4 gives authority to the holder of the permit to make the excavation. Section 5 provides that the party shall properly refill excavations in unpaved streets. Section 6 makes it the duty of the Borough Engineer to take over the backfilling in all paved streets. The base of the pavement is cut away 10 in. on all sides of the trench, and where the trench width is less than 30 in., a 5-in. concrete base is laid; over 30 in., a 6-in. base. Violation of the ordinance entails a fine of $25. Section 9 makes it unlawful, except by special vote of the town council, for any person, partnership or corporation to dig or make a trench, ditch or excavation in the streets or alleys of the borough between Dec. 1 and Apr. 1, unless for the purpose of making necessary repairs to leaking gas or water pipes, or to remove an obstruction in sewers, under a penalty of from $5 to $100.

The National Grange on Road Improvement—The discussion of highway improvement by the National Grange, at the recent annual convention in Wilmington, Del., is of much interest because of the political influence, both local and national, wielded by this nation-wide association of farmers. The meeting unanimously adopted a report of a special committee of seven, of which T. C. Atkeson, of West Virginia, was chairman, appointed last year to amplify the Grange road policy. The committee stated that the Grange had been the pioneer in the good roads movement; that the sentiment for good roads was practically universal, but that there was great danger of this sentiment being diverted toward the construction of scenic highways and boulevards, for the benefit of tourists and pleasure-seekers, rather than for the business interests of the general public. The convention, in adopting the committee report, expressed its opposition to the many bonding schemes advanced by those seeking touring roads, and urged the legislative committees of the Grange, both national and state, to use every honorable endeavor to obtain first business roads that will serve the best interests of both producer and consumer. In part, the resolution read:

Roads are local affairs and their control should remain with the people in whose midst they are located. The national and state governments may provide general standards for construction and maintenance of roads and may protect themselves by inspection. We call the attention of all our people to the grave danger in top-heavy, bureaucratic control of road administration, and to the fact that much of the support for the good roads comes from those who are more anxious to build roads for bonds than to sell bonds for roads.

PERSONALS

Mr. R. W. Reynolds has resigned as General Manager of the Springfield (Mass.) Street Ry. Co. to become General Manager of the Mesaba Street Ry. Co., Virginia, Minn.

Mr. Stephen E. Wilson, who designed the new municipal garbage-reduction plant at Dayton, Ohio, has been employed to supervise its construction and manage its operation.

Mr. David McNichol, Vice-President of the Canadian Pacific Ry., Montreal, Que., has resigned. He is succeeded by Mr. George Bury, Vice-President, who heretofore has made his headquarters in Winnipeg, Man.

Mr. E. W. McKenna has resigned as Vice-President of the Chicago, Milwaukee & St. Paul Ry. after over half a century of railway service, begun in 1862 as a messenger and telegraph operator with the Pennsylvania R.R.

Mr. Milo M. Backus, recently Supervisor of the Illinois Central R.R., at Princeton, Ky., has been promoted to be Roadmaster of the Springfield division, with headquarters at Clinton, Ill., succeeding Mr. Lewis H Bond, transferred.

Mr. H. S. Morse, M. Am. Soc. C. E., formerly Engineer in charge of sewerage investigations at Cincinnati, Ohio, is now Engineer of the Ohio Institute for Public Efficiency, Hartman Bldg., Columbus, Ohio. He is temporarily engaged on some special work for the Cincinnati Bureau of Municipal Research.

Mr. H. M. Flanders, Engineer of Maintenance-of-Way of the Springfield (Mass.) Street Ry. Co., has been promoted to be General Manager, succeeding Mr. R. W. Reynolds, resigned as noted elsewhere. Mr. Flanders was educated at the Massachusetts Institute of Technology and was formerly with the Newton (Mass.) Street Ry. Co.

Mr. Otto Lemberger, formerly a consulting engineer and surveyor of Chihuahua, Mexico, who returned to his native country of Austria in 1913 to engage in stereophotographic survey work under Capt. von Orel, the inventor of the stereoautograph, has been made a lieutenant in the Austrian Army and is now on the fighting line.

Mr. Richard Sachse has been appointed Chief Engineer of the California Railroad Commission, with headquarters in San Francisco. Mr. Sachse entered the service of the Commission in 1911 as Assistant Engineer. He was promoted to the position of Principal Assistant Engineer in 1913, and has been Acting Chief Engineer since December, 1913. Prior to his service with the Commission he had been with the Western Pacific Ry., the Southern Pacific Co. and the United States Reclamation Service.

OBITUARY

John C. Muir, General Superintendent of the Chicago, Terre Haute & Southeastern R.R., died at his home in Terre Haute, Ind., Nov. 4, at the age of 50 years. His railway experience began in 1879 as a messenger boy with the Atchison, Topeka & Santa Fé Ry.

Charles Willard Kettell, a retired mechanical engineer, died Nov. 18 at his home in Lexington, Mass. He was born in Charlestown in 1848, and graduated from Harvard University in 1870 and from the Lawrence Scientific School in 1873. He practiced his profession of mechanical engineering first in Fitchburg, Mass., and later in Boston. He is survived by a widow and a daughter.

Forrest E. Barker, Chairman of the Massachusetts Gas and Electric Light Commission, died Nov. 20, in Washington, D. C., where he had gone to attend the annual convention of the National Association of Railway Commissioners. He was born in Exeter, N. H., in 1853, and graduated from Wesleyan University, Middletown, Conn., in 1874. He studied law and for a time practiced in Worcester, Mass. Mr. Barker was appointed a member of the Massachusetts Gas and Electric Light Commission in 1885, and ever since then had been one of its ablest members.

Frank H. Rogers, Superintendent of Construction, United States Treasury Department, died recently in Wheeling, W. Va., from the effects of an accident. He was supervising the construction of a Federal building in Wheeling and was injured by the falling of a block of stone. He was born in West Newbury, Mass., in 1871, and graduated from the Massachusetts Institute of Technology in 1896. He was employed in the city engineering department of Boston, Mass., until 1905, when he was appointed Superintendent of Construction on United States Government work. He is survived by a widow and a two-year-old daughter.

[illegible] S. Martin, former Editor of the "General Electric Review" [illegible] member of the editorial staff of the "Electrical World," died recently at the Boulogne Hospital, [illegible] wounds received in the battle of [illegible]. He [illegible] British Army. Mr. Martin was [illegible] of [illegible] Smiles, author of the "Lives of the [illegible]," and [illegible] brother of T. C. Martin, Past-President of the American Institute of Electrical Engineers, Secretary of the National Electric Light Association. He was born in England and received his education at the Central Technical [illegible]. He was 27 years old.

ENGINEERING SOCIETIES

COMING MEETINGS

AMERICAN INSTITUTE OF ARCHITECTS.
Dec. [illegible] Convention at Washington, D. C. Secy., D. [illegible] Kendall [illegible] Boyd, The Octagon, Washington, D. C.

ASSOCIATION OF AMERICAN PORTLAND CEMENT MANUFACTURERS.
Dec. [illegible] Annual meeting in New York City. Secy., Percy H. Wilson, Bellevue Court Bldg., Philadelphia, Penn.

AMERICAN MINING CONGRESS.
Dec. 7-11. Annual meeting at Phœnix, Ariz. Secy., J. F. Callbreath, Denver, Colo.

NATIONAL SOCIETY FOR THE PROMOTION OF INDUSTRIAL EDUCATION.
Dec. [illegible] Convention at Richmond, Va. Secy., C. A. Prosser, 140 W. 42d St., New York City.

SOCIETY OF NAVAL ARCHITECTS AND MARINE ENGINEERS.
Dec. [illegible]-11. Annual meeting at New York City. Secy., D. H. Cox, 29 W. 39th St., New York City.

AMERICAN ROAD BUILDERS' ASSOCIATION.
Dec. 14-18. Convention at Chicago, Ill. Secy., E. L. Powers, 150 Nassau St., New York City.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.
Dec. 28-30. Annual meeting at Chicago, Ill. Secy., F. M. White, Madison, Wis.

SOCIETY OF CONSTRUCTORS OF FEDERAL BUILDINGS.
Jan. 4-6. Convention at Washington, D. C. Secy., T. R. Mash, 4213 Westminster Ave., Philadelphia, Penn.

ASSOCIATION OF GOVERNMENT CONTRACTORS.
Jan. 4-7. Annual meeting at Washington, D. C. Secy., Algernon Blair, Montgomery, Ala.

AMERICAN SOCIETY OF ENGINEERING CONTRACTORS.
Jan. 12. Annual meeting at New York City. Secy., J. R. Wemlinger, 11 Broadway, New York City.

AMERICAN WOOD PRESERVERS' ASSOCIATION.
Jan. [illegible] Convention at Chicago, Ill. Secy., F. J. Angier, Mt. Royal Station, B. & O. R.R., Baltimore, Md.

AMERICAN SOCIETY OF HEATING & VENTILATING ENGINEERS.
Jan. [illegible] Annual meeting at New York City. Secy., J. J. [illegible], [illegible] W. [illegible]th St., New York City.

AMERICAN CONCRETE INSTITUTE.
Feb. [illegible] Convention at Chicago, Ill. Secy., E. E. Krauss, Harrison Bldg., Philadelphia, Penn.

Compressed Gas Manufacturers' Association—The annual meeting will be held at the headquarters of the Association, [illegible] Madison Ave., New York City, at 2:30 p.m., Jan. 18. The Secretary is [illegible].

Springfield (Mo.) Engineers' Club—An Engineers' Club at Springfield, Mo., was recently [illegible] organized. The membership of [illegible] is composed largely of engineers of the Frisco [illegible], whose headquarters are in that city.

National Conference on Concrete Road Building—[illegible] [illegible] La Salle St., Chicago, Ill., states that the [illegible] national conference on concrete road building will probably be held some time in February, 1915.

American Society of Mechanical Engineers—At the annual meeting, [illegible] New York, [illegible] there will be an [illegible] under the auspices of the Public Relations Committee of the Society.

American Wood Preservers' Association—The [illegible] annual convention will be held in Chicago, Jan. [illegible], with headquarters at the [illegible] Hotel. The program will be [illegible]. The Secretary is F. J. Angier, [illegible] R.R. Co., Baltimore, Md.

Society of Constructors of Federal Buildings—The [illegible] annual convention of the Society will be held in the rooms of the Washington Architectural Club, [illegible], Washington, D. C., Jan. 4-6. [illegible] should be [illegible] Secretary, T. R. Mash, 4213 Westminster Ave., Philadelphia, Penn.

New England Water Works Association—At the Jan. [illegible] meeting, in Boston, Mass., in addition to the [illegible] of [illegible] the [illegible] discussions of the [illegible] will be continued. The Secretary is [illegible].

Duluth Members of American Society of Civil Engineers—A branch of the American Society has just been organized in Duluth, Minn., for the benefit of the 17 members of the national body, living in the city and vicinity. The president is F. E. House, President of the Duluth & Iron Range Ry., the secretary is Walter G. Zimmerman, Manager of the American Bridge Co. Meetings will be held from time to time.

Association of Government Contractors—The third annual meeting of the Association will be held in Washington, D. C., Jan. 4-7, with headquarters at the Hotel Raleigh. This meeting will include a conference on the first day with manufacturers, dealers and subcontractors, on the second day a joint meeting will be held with the Society of Constructors of Federal Buildings.

Engineers' Society of Philadelphia—Plans are being drawn by Philadelphia engineers to unite their several organizations into one body, to be called the Engineers' Society of Philadelphia, with headquarters at the present address of the Engineers' Club, 1317 Spruce St. A committee has drafted by-laws and regulations, which will be presented to each association for acceptance. It is said that there will be about ten such organizations in the new society.

American Society of Agricultural Engineers—The annual meeting will be held at Chicago, on Dec. 28-30. One session will be devoted to a series of papers on "The Place and Field of the Agricultural Engineer," by the deans of half a dozen engineering colleges. Another session will be devoted to papers and discussions on education in agricultural engineering. At the third business session there will be papers on soil treatment, the fuel economy of small gas engines, the draft of farm wagons, and the design of farmhouses. The Secretary is F. M. White, Madison, Wis.

Aëronautical Society of America—What is termed the first joint conference on aviation will be held by the Aëronautical Society of America, in conjunction with other national engineering organizations, Feb. 5-6, 1915, when inventions tending to increase the stability and safety of flight in heavier-than-air machines will be considered. Those wishing to submit their inventions are invited to communicate with the Technical Board of the Society, at 29 West 39th St., New York City. Other societies represented will be the American Society of Mechanical Engineers, the American Mathematical Society and the American Physical Society.

The American Society of Engineering Contractors—The annual meeting will be held in New York on Jan. 12. At a recent meeting of the Board of Directors a report of the record, efficiency and accomplishment of the various committees was submitted by a special committee appointed to revise the present work of the Technical Standards committees. It is very probable that several committees, whose fields overlap those of the larger engineering societies, will be discontinued. It is the desire of this Society to concentrate its efforts on the solution of the problems facing engineering contractors. The Secretary is J. R. Wemlinger, 11 Broadway, New York City.

American Association for the Adoption of the Metric System—This organization was recently launched under the auspices of the Oregon Society of Engineers. Its object is to educate the American public in the advantages of the metric system of weights and measures, to extend its use in the United States, and to [illegible] a rational plan whereby it may be [illegible] adopted without [illegible] or [illegible] loss to existing industries. There are no restrictions as to membership. The fee is $1. Temporary officers have been selected who will serve until the first meeting of the association, which will be held in San Francisco in connection with the International Engineering Congress, Sept. [illegible], 1915, when permanent officers will be chosen. The temporary secretary is J. A. [illegible], Portland, Ore.

Boston Society of Civil Engineers—The Society has recently detailed a member who has a faculty [illegible] to get accounts of its activities into [illegible] suitable for the newspapers. The Society, which is the oldest in the country, and now has a membership of [illegible], is beginning to feel that it should take an active interest in local affairs and especially in legislation affecting engineering matters. It is also beginning to realize that its actions will have greater weight if the people and the legislature are first made to appreciate that its members are responsible for nearly every [illegible] of engineering [illegible] and construction in New England. That [illegible] is [illegible] welcomed by the daily press was shown by the space which the Boston papers gave to an address [illegible] before the Society on Nov. 18 by Henry M. Waite, City Manager of Dayton, Ohio, and formerly City Engineer of Cincinnati. The address was on the city-manager plan of municipal government.

VOLUME 72 DECEMBER 10, 1914 NUMBER 24

Some Bridges on the Columbia Highway

By K. P. Billner*

The Columbia Highway, now being constructed, follows the south bank of the Columbia River from Biggs, Ore., through Portland, to Astoria.

The magnificent scenery along the route, particularly between Portland and Hood River, is unsurpassed in this country. Along this portion of the highway are numerous mountain streams and ravines which had to be spanned, and the writer was asked to work out the designs for the bridges. In this work it has been his aim to build structures which would harmonize with the mighty surroundings and at the same time give the factors of safety and low cost their due consideration. No standard types were adopted, but reinforced - concrete structures had the preference over steel bridges.

Below are given descriptions of some of the most noteworthy of the structures.

Latourelle Bridge

The bridge at Latourelle (Figs. 2-3) is an original type by the writer, although its principles are borrowed from the French expert, the late M. Considère. The principal characteristic of this bridge is its lightness. It is 312 ft. long and 97 ft. high to grade of the roadway. It has a 17-ft. driveway and the total width, including two cantilever sidewalks and railings, is 25 ft. The concrete above ground amounts to only 560 cu.yd., making presumably the lightest concrete bridge, relative to its dimensions, in this country. It was desired to erect a light structure for several reasons, among which the difficulty in securing a firm foundation was foremost. The underlying bedrock is covered with a layer of silt and boulders to an average depth of 25 ft. on the western bank, while on the east side of the creek is a deposit of drift sand, 50 ft. in depth. The cost of building abutments and piers for a heavy type of bridge would have been very high with these conditions of the foundation to contend with.

Substructure—The abutments, as well as the piers, were founded on bedrock. The west abutment and the two central column bents were placed directly on bedrock. The east abutment was put on four columns, two 4 ft. square and two 5 ft. square. The average depth of these

Fig. 1. Footbridge over Lower Multnomah Falls, on the Columbia Highway, Oregon

(Length of span, 45 ft.; height above creek, 105 ft., erected September, 1914.)

*Engineer, Oregon State Highway Commission, Portland, Ore.

[illegible] 15 ft. from the [illegible] side of the abutment on the rock. The tops of the [illegible] columns are connected to the bottoms of the [illegible] columns by inclined struts which transmit the thrust from the arches down to the rock foundation.

SUPERSTRUCTURE—Each end of the bridge consists of two girders, which carry a set of columns and struts on which the roadway is erected. [illegible] cantilever [illegible] the cantilever action which might develop was not considered in the calculations of the stresses in the structure. The central portion of the bridge consists of three [illegible]-ft. arch spans. Two arch ribs carry each span. These ribs are 20 in. square and are reinforced by eight longitudinal 1-in. square bars and No. [illegible] banding of [illegible] diameter and 2-in. pitch. The ribs are parabolic in shape. The deck floor and any superimposed load are carried to the arch ribs by vertical columns placed at 16-ft. centers.

To resist against bending moments in the arch ribs from partial loading, diagonal members are inserted between the junction points of the arch ribs and the vertical columns and the deck and the columns. These diagonal members are subjected to alternately compressive and tensile stresses and therefore special care had to be exercised in the construction of the junction points. The reinforcing bars of the diagonals are hooked around the longitudinal reinforcement of the arch ribs and also around the longitudinal reinforcement of the girders, which form the [illegible] of the deck. Where it was found necessary to [illegible] [illegible] were [illegible] in the forms. The joints [illegible] during the [illegible] of the bridge. The balustrades are made of artificial stone.

QUANTITIES AND UNIT STRESSES—Permissible stresses [illegible] generally [illegible]: Concrete in bending, 600 lb. per sq.in.; [illegible] compression, [illegible] per sq.in.; [illegible] per sq.in.; [illegible] in tension, 16,000 lb. per sq.in.; [illegible] in bearing, [illegible] lb. per sq.in.

LOADINGS—A uniform load of 100 lb. per sq.ft., a concentrated load of 15 tons, and an impact factor of 25% were selected.

The analysis was made for three conditions of loading: First, A uniform load over the entire bridge; second, half the span of one arch loaded; third, two spans were fully loaded, with no load on the third span.

The springing points of the arches were restrained from moving by making the main columns act as beams with double reinforcements.

CONSTRUCTION—The falsework was erected with a tower at each end of the bridge, and a cableway. All of the forms were built and braced before the concreting of the superstructure commenced. The main columns, which are about 90 ft. high, were poured in sections which were allowed to set for a few hours before the next pouring commenced. The arch ribs were poured simultaneously, commencing at the springings and working toward the crowns. The deck, containing 250 cu.yd. of concrete, was poured in a continuous operation lasting [illegible] hours. The maximum settlement during the pouring of the arches was [illegible] in. The deck was poured after the arches had set for 12 days. No settlement took place while the deck was being poured or after. The centers were struck six weeks after the pouring of the arches.

The principal advantage of this type of a bridge is the small amount of concrete required. The added expense of formwork is more than paid for by the saving in materials. The bridge makes a very pleasing appearance.

The contractor for the bridge was [illegible], of Portland. Messrs. [illegible] and [illegible] had a subcontract for the forming and placing of the steel. Credit is due them for the very satisfactory workmanship and for the [illegible] finished structure.

FIG. 2. BRIDGE AT LATOURELLE ON THE COLUMBIA HIGHWAY

BRIDGE AT [illegible] DELL

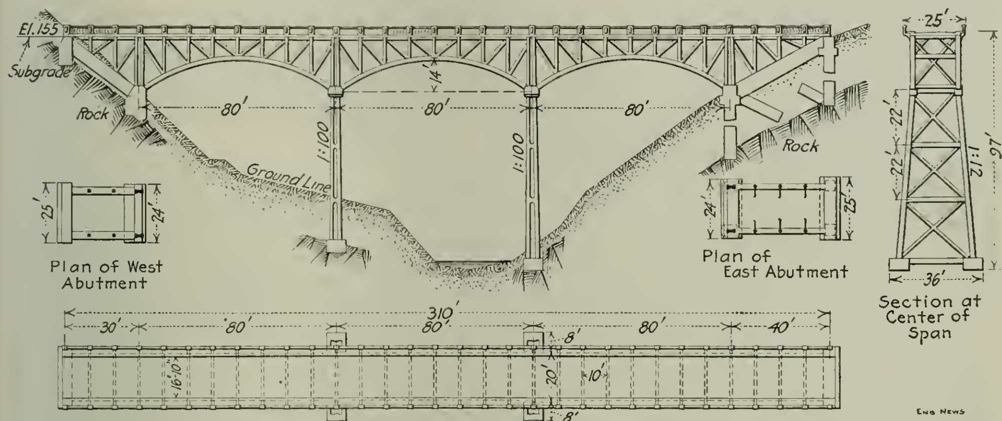
This bridge (Figs. [illegible]) is of a standard type, but has one original feature in the reinforcing of the spandrels.

The spandrels are reinforced in such a way as to make them act as girders, and are capable of sustaining the bending moment from the live load over half the span. These spandrels, therefore, will distribute the loading on the arches. The influence of the stiffening of the spandrels, although of great value, has not been considered in the determination of the dimensions of the arch ribs. The clear spans in the Shepherds Dell bridge are each 100 ft.

Viaducts

Among problems which arose in the construction of the Columbia Highway were two which necessitated the building of viaducts. A glance at Figs. 7 and 9 will be sufficient to explain the situation. The Highway at these places is located on a steep mountainside, at the foot of which the Oregon-Washington R.R. & Navigation Co.'s line is located. To excavate a 24-ft. roadway out of the hillside would have meant the moving of an enormous quantity of earth with no place to dump it. In order to avoid this, the viaducts were erected.

Fig. 8 shows a cross-section of the viaduct at Multnomah Falls and is typical of the design of these "side-hill" viaducts. Essentially the construction is a solid reinforced-concrete slab, crowned to the road crown, which rests on transverse floor-beams spanning between columns on the low side and a continuous girder on the high side. These columns are spaced every 20 ft. and foot on prismatic bases. The up-hill girder rests on square concrete plates and the plates and column footings are tied together by reinforced-concrete struts taking the slope and embedded in ground. Longitudinal stiffness is also given by girders at the top of the columns under the railing.



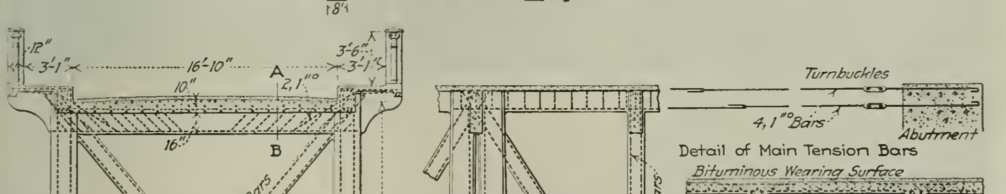


Fig. 3. Details of Latourelle Bridge

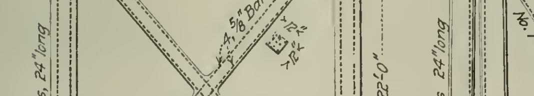

Fig. 7 shows the viaduct from the river side. The peculiar arched railing should be noted. This type of railing was used on a number of the other structures. The total length of these structures is 1260 ft. Besides eight concrete bridges erected on the Highway, there is to be mentioned a footbridge over the lower Multnomah Falls 105 ft. in the air. This bridge, shown in the first-page view, was donated by S. Benson, of Portland, Ore. The total length of roadway of these bridges and viaducts is 2012 ft. The contract price was only $76,500.

[illegible] per square foot of [illegible] surface varies from [illegible] for the viaducts to [illegible] for the high bridges. The [illegible] structures east of [illegible] were erected by the [illegible] Co., of Portland. All of the structures are well [illegible].

PERSONNEL

The Columbia Highway in Multnomah County is being constructed by S. C. Lancaster, Assistant State Highway Engineer, Consulting Engineer for Multnomah County. H. L. Bowlby, State Highway Engineer, J. B. [illegible], Assistant Roadmaster, [illegible], Chairman of the Board of County Commissioners. The writer was appointed engineer for the design and construction of the bridges.

[illegible] Two Views of the Shepperd's Dell Bridge on the Columbia Highway, Oregon

Standards for Gas and Electric Service in Illinois

[illegible] for gas and electric service were recently [illegible] by the Illinois Public Utilities Commission, becoming effective [illegible] 1914. They were prepared by [illegible], Chief of Service Department, and [illegible] Gas Engineer, under the direction of [illegible], Chief Engineer. Companies are required to [illegible] records of [illegible] interruptions, [illegible] of supply, [illegible] and annual [illegible]. Any meter must be tested on complaint [illegible]. [illegible]

[illegible]

gas is defined as volume under existing conditions but at a temperature not over 75° F. Meter provers must determine the accuracy of meters within ½%. When installed, meters must be set not over 1% in passing gas at 6 cu.ft. per hr. per rated light capacity. Meters must be tested at least once in five years. If a meter is accurate within 2%, no adjustment of bills is involved. The commission will test meters at fees ranging from $1 to $8, depending on capacity. A company with output exceeding 20,000,000 cu.ft. per year must have a complete standard calorimeter outfit, and the heating value of manufactured gas must be determined on at least three days a week; for natural gas, three times a year. Manufactured gas must have a total calorific value of not less than 565 B.t.u. per cu.ft., and it must not drop below 550 at any time. Where the gas is carried at [illegible] pressure or over, an allowance of [illegible] B.t.u. in the monthly

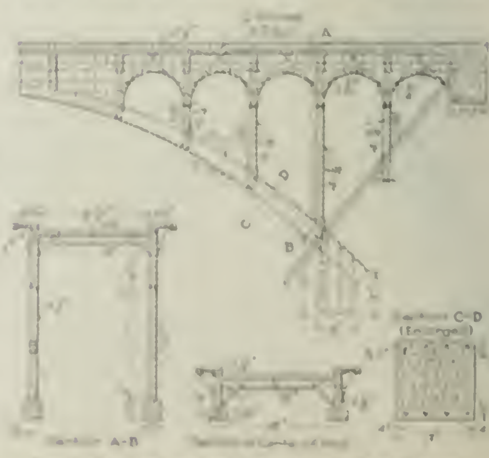

Fig. 7. Details of the Shepperd's Dell Bridge

Fig. 7. Side-Hill Viaduct at Multnomah Falls, 860 Ft. Long

average is made and the minimum value is placed at 520 B.t.u. Sulphur content is limited to 30 grains per 100 cu.ft.; hydrogen sulphide to 1 grain. Outlet pressure must not be less than 2 or more than 8 in., except under special contract. Daily variation of pressure at any outlet must not be greater than 100% of the minimum. Each company must have one or more portable graphic record-

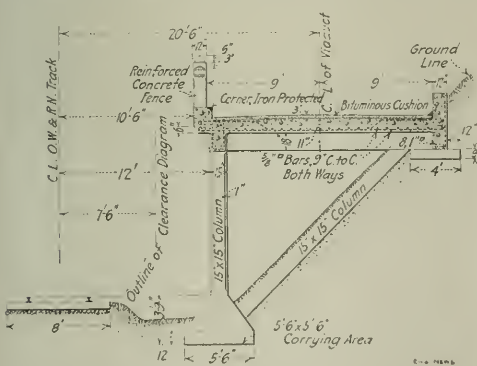

Fig. 8. Section of Multnomah Falls Viaduct

ing pressure gages and must make frequent pressure surveys. Companies must make street-main extensions free of charge, provided the length of the entire extension is not greater than that obtained by allowing 100 ft. per consumer for a low-pressure system and 200 ft. per consumer for a high-pressure system. Extensions above the free limit must be made if proper compensation is offered.

Electricity-supply companies are required to have working meter standards, accurate within ¼%, and check standards. In testing a meter, two determinations agreeing within ½% must be made at 10% and at 75% rated capacity or full connected load. The average error, of these two values, of a meter at installation must be not over 2%. A meter in service may have an error of not more than 4% before adjustment of bills is necessary. The commission will test watt-hour meters at figures ranging from $2 upward. The voltage variation on constant-potential lighting systems must not exceed 5% of the adopted standard voltage; for power circuits the variation may reach 10%. Voltage surveys and records must be made by the company. Sustained variations of frequency on alternating-current systems must be not over 5% of a fixed standard.

Station records must show time of starting and stopping generating apparatus; starting and disconnecting

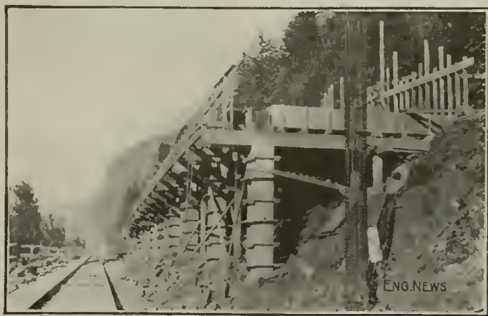

Fig. 9. Multnomah Falls Viaduct under Construction

street-lighting circuits; reading of instruments necessary to determine character of load; all interruptions to service, with time, duration, extent and cause. An interruption is defined as the interval during which voltage falls below 50% normal. Grounding of all secondaries of alternating-current circuits is required in all new construction and according to the rules of the National Electrical Code. Free extensions of service must be made, provided any such line requires no more than twice as many poles at standard spacing as there are individual applicants. Extensions above the free limit must be made if proper compensation is offered.

⁂

British Locomotive Exports—In spite of war, shipments for nine months ending Sept. 30 had a value of $14,648,000, compared with $10,337,000 and $7,155,000 for similar periods in 1913 and 1912 respectively. The locomotives went mostly to India, Australia, Argentina and South Africa.—London "Engineering"

New York Rapid Transit Railway Extensions*

By F. Lavis†

IX--Underpinning Buildings along the Line

Under the general heading of "protection of adjacent buildings" the specifications provide for three classes of work.

A. Buildings "which are supported on firm soils" and bearing such a relative position in regard to the subway structure that a slope "represented by 1 ft. vertical to 2 ft. horizontal, inclined downward from the bottom outer edge of the building foundation, passes beneath the bottom outer edge of the completed subway structure" [illegible] to be taken care of by the contractor, and such [illegible] therefor may be [illegible] in the price for excavation.

B. When necessary to secure adjacent buildings so as to prevent bringing an unusual pressure on the subway structure when completed, the contractors are required to "safely and permanently underpin adjacent buildings the foundations of which are above the bottom of the adjacent subway excavation." This work is paid for at a price bid per front foot of the buildings. The latter are classified according to height: less than seven stories, seven to twelve stories, and over twelve stories. The prices for this work [illegible] range from [illegible] to [illegible] per front foot for 7-story buildings and from [illegible] to [illegible] with an average of about $150 for buildings 7 to 12 stories. The prices are, however, very irregular and [illegible] to [illegible] between [illegible] and [illegible]. Bids for underpinning buildings over 12 stories range from [illegible] to [illegible] per front foot and [illegible] too few and erratic to be of any use as a guide to the cost of the work.

C. In certain cases where underpinning is not considered necessary but where buildings have to be secured and maintained during construction, there is a price bid per front foot for "maintaining, protecting and securing." These prices range from $15 to $60 and average about $40.

It is generally required that underpinning be carried down to solid rock or to at least 2 ft. below the lowest excavation for the subway, if rock is not encountered before that depth is reached.

Often when the necessary excavation for the subway structure takes a fairly large proportion of the width of the street, the excavation of the "first lift" is carried out to the full width of the street between building lines and to the depth of the cellar, thus providing easy access for working as is shown in Fig. 53A. The excavation of this first 10 ft. is generally first carried ahead the whole length of the section, or for a considerable portion of it, and this is followed by the underpinning before any further excavation is undertaken.

Probably the most common way of supporting ordinary buildings is to temporarily carry the walls to be supported on needles, generally I-beams, as shown in Fig. 53A and extend the foundation walls down to rock if this is not too deep.

In cases where the depth to rock or to the required bottom of foundation is deep, piers (from 2 to 3 ft. square for ordinary buildings 5 or 6 stories high) are usually sunk at intervals of 10 to 15 ft. The spacing of the piers depends, of course, on the position of the piers or columns of the building which require direct support, and the front wall of the building between the piers is supported on two or more I-beams spanning the space between these piers. The excavation of the pits for the piers is usually made by hand, the well being sheeted, and the piers are built of concrete. In some cases, instead of the concrete piers, 12-in. pipes in short lengths are sunk either by driving with a weight or with a water jet, the subsequent procedure being the same.

To avoid supporting the buildings on needles, two methods have been used, somewhat similar in principle. Concrete piers 2 ft. square are sunk to rock in pairs, one inside and one outside the wall, each pair 10 to 12 ft. apart, or instead of the piers, 12-in. wrought-iron pipes in lengths of about 4 ft. with inside sleeve couplings are sunk and filled with concrete, the tops of these piers or pipes being 20 to 30 in. below the cellar floor. I-beams of suitable size (50 to 60 lb. generally for ordinary buildings) are then laid on top of these piers or pipes parallel and adjacent to the walls of the buildings; small holes are then broken through the wall and smaller I-beams put through spanning the first two and the walls wedged up on these, as shown in the sketch in Fig. 53B.

On one section where a building of moderate size had to be taken care of, piers were sunk to rock (or to the required depth) and then the walls were widened out at the top in the direction of the line of the building, as shown in Fig. 53C, and filled with concrete, in which reinforcing rods were placed. These piers were 30 to 40

ft. apart and the space between them was spanned by two 30-in., 200-lb. Bethlehem beams, which were placed in niches cut in the wall to receive them.

On Section 14, Lexington Ave., W. Melvin, Superintendent for the McMullen & Hoff Co., devised a form of

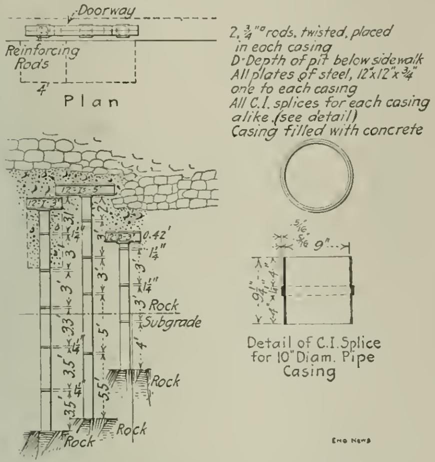

FIG. 54. UNDERPINNING BUILDINGS WITH STEEL-PIPE PILES FILLED WITH CONCRETE

shield on the principle of the tunnel shield, but reduced to its simplest elements, to sink 3-ft. 6-in. cylinders vertically for underpinning. The apparatus is shown by the drawings, Fig. 55, and, as will be seen, consists simply of a cylinder of ¼-in. boiler iron about 3 ft. long with a 3x4-in. angle bent to circular form to fit inside just back from the lower end. Four segments, as shown in the drawing, form an 18-in. ring, which is added to the bottom of the caisson inside the tail of the shield as this latter is shoved down. The shield is "shoved" by four jack bolts, bearing against the 3x4-in. angle of the shield and reacting against the last ring.

The material is removed by means of small buckets which are raised by a hand winch and taken out of the top through the air lock. On account of the small working compartment only one man can work at the excavation, but usually there is another puddling the joints and sealing the shaft.

The shield, of course, was left in the bottom when the caisson was concreted. These caissons were sunk about 20 to 25 ft. apart, directly under the front walls of the buildings, the location depending on the location of the main columns or piers which it was desirable to support directly. The space between them was spanned by two 26-in., 150-lb. Bethlehem beams on which the wall was supported directly, as shown in Fig. 53E.

At one point on Section 13, Lexington Ave., where the rock was quite near the surface and the necessary excavation close to the building line, a slip occurred in the rock, endangering the front of the building. In order to avoid blocking up in the excavation, long I-beams were used as cantilevers, blocked up in the cellar just back of the front wall and running back under the back wall, against which they were blocked and which afforded the necessary reaction, as shown in the sketch in Fig. 53D.

On Sections 8, 9, 10 and 11, Lexington Ave., three methods were used: *First,* the common one of supporting the buildings on needles while the walls were carried down in trenches to rock, this being usually adopted when the rock was not deep. *Second,* piers of concrete about 5 to 6 ft. wide and 8 to 10 ft. long were sunk to rock or subgrade and spanned by two or sometimes three I-beams on which the building wall was carried. This method was usually used where the rock or subgrade was deep, say 10 ft. or more below the basement floor of the building. *Third,* 10-in. iron pipes in lengths of 3 to 5 ft. with inside sleeve couplings were sunk under the walls and capped with I-beams, as shown in Fig. 54. The pipes were forced down by jackscrews reacting against the walls of the building, and were put down under columns or sections of the wall which carried the load. They were sunk dry and the material inside excavated with small orange-peel scoops. The small boulders encountered were taken out by a sort of net on the end of a pole called a "snare." They were supposed to be sunk to rock, sealed to it by a rich cement mortar, and filled with concrete in which were embedded two ¾-in. square steel rods.

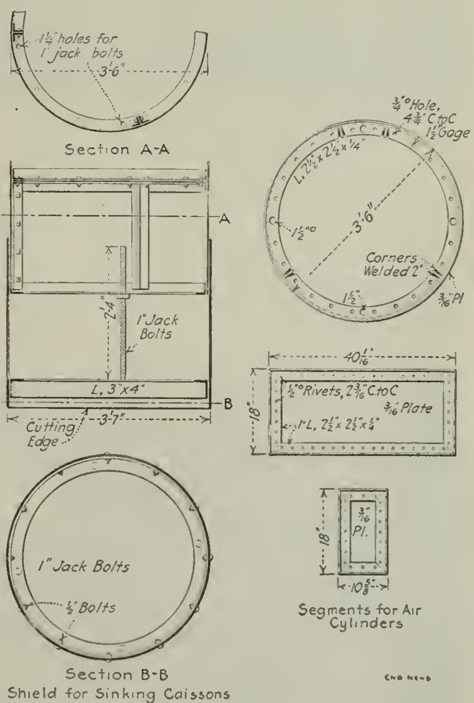

FIG. 55. SECTIONAL CAISSONS OF CAST IRON SUNK WITH SHIELD

This method of underpinning is quite effective and safe in many cases and, of course, is very much cheaper than either of the first two methods, if the foundations have to be carried down to any great depth. The defects are that it is sometimes difficult to tell if the pipes are on solid rock or on a boulder, and if the excavation for the subway or other purpose comes close to the building line, the front of the pipes may be uncovered, leaving

Fig. 56. Putting down Hollow Steel Pile with Hydraulic Jack Reacting against Building

[illegible] unsupported columns. So far as could be learned, however, where they have been used so far, they have served their purpose and no actual difficulty or failure has been encountered. This work was done by the Underpinning & Foundation Co., under a subcontract from the principal contractors.

A method which obviates the necessity of supporting the buildings on needles was developed and used on Sections 1 and 2 of the Broadway line. It consists essentially in tying the foundation columns together with a reinforced-concrete mattress or girder, as shown in Fig. 59, then sinking pits or piles under it to the required depth. Built-up steel girders or I-beams are first laid along on either side of the columns and parallel to the face of the building, at about the level of the basement floor, or just below it, one outside and one inside and tied to each column and to each other. These girders are made up of short sections, on account of the confined space in which they have to be handled, and a convenient form is one made up of four angles latticed together, and riveted so as to be continuous for the length of the front of the building (see Fig. 58), though I-beams are used in some cases. Light hitches are cut in the piers to get a firm bearing, and the girders or I-beams are tied together firmly with rods or sometimes with steel-wire ropes, the whole being then concreted, making a continuous reinforced-concrete girder supporting the whole front. The photograph, Fig. 58, shows in the foreground the two latticed girders and behind that the completely concreted beam or girder.

Rectangular pits are then sunk at intervals under the girder, as shown in the sketch, Fig. 59, and in spaces between the column footings so that the ground under these latter remains undisturbed. The pits are sheeted with horizontal sheeting, and are sunk to the necessary depth, i.e., to 2 to 3 ft. below the subgrade of the subway structure, and filled with concrete. Care is taken not to have the open pits close together. About two at a time, some distance apart, are put down, filled and blocked under the concrete girder before others are started. If water is encountered, hollow steel piles in short sections are sunk from the bottom of the pits below the water level and filled with concrete. All piles are tested by hydraulic pressure to take up any slight settlement.

There are two methods of sinking these hollow steel piles which are quite extensively used, one by the use of

Fig. 57. Underpinning with Needles, Building at [illegible] Broadway

Fig. 58. Underpinning with a Latticed Girder

hydraulic- or screw-jacks reacting against the building above, as shown in the photograph, Fig. 56, and the second, to drive them by a hammer. The first is, it is stated, a patented process. Where the hammer is used it generally consists solely of a weight, about 300 lb.,

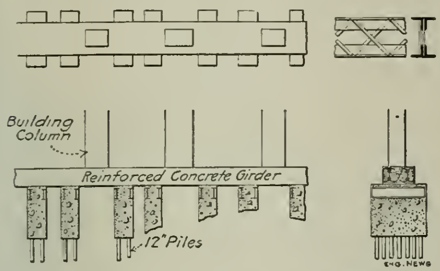

FIG. 59. SKETCH ILLUSTRATING UNDERPINNING WITH REINFORCED-CONCRETE GIRDER

suspended from a rope passing over a single block attached to the floor above the pit, and running to a small single-drum hoist. The fall is usually only a few feet and the hammer is guided by hand by a man standing near the pile being driven. A square cast-iron cap is used on top of the pile.

An interesting detail of the horizontal sheeting so generally used in sinking the pits for underpinning and other purposes is the method of chamfering the corners of the

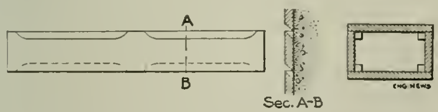

FIG. 60. HORIZONTAL SHEETING FOR SINKING PITS

boards so as to allow of packing the ground solid behind them as they are placed (see Fig. 60). The boards on two opposite sides are cut so that they fit inside those on the other sides, making a brace, and short blocks are spiked on to hold the short sides as shown in the plan. The long sides are placed first, and made to give a firm driving fit to the short ones. Each width is firmly packed as it is placed.

The pits are filled with concrete up to within about 12 or 15 in. of the bottom of the concrete girder. When the concrete in the pit has set, short sections of I-beams are placed on top of it and wedges are firmly driven between these I-beams and the bottom of the foundation girder. This holds the latter while the other pits are being put down, the shrinkage in the concrete in the pits being taken up from time to time by the wedges and the whole finally completely filled in, after all shrinkage and settlement of the new foundation have taken place.

The foundations of the Havemeyer Building (11 stories) are on spread brick piers on wooden piles, the bottom of the brick and the top of the piles being at approximately the level of the floor of the subway. To protect these foundations, additional hollow steel piles were sunk under the front edges of the building piers and then a double row of steel sheet piling 10 or 12 ft. long and with a space of about 3 ft. between the rows was driven as additional protection. This acts as a coffer-dam and not only will tend to prevent any disturbance of the ground around the piles, but also to retain the level of the ground water.

In turning from Church St. through Vesey St. to Broadway, it was necessary to obtain easements under private property at each of the corners in order to get around. One of these is under Trinity Parish House and the other under the old Astor House. That portion of the latter under which the tunnel passes was dismantled and taken down, the city agreeing to provide foundations for a new building along each street line. Open trenches were sunk through the sand to a depth of about 30 ft. and from the bottom of these trenches pneumatic caissons are being sunk to the required depth. The sinking of the caissons is done under a special subcontract by the Foundation Company.

The Trinity Parish House is a four-story brownstone building about 30 ft. wide and 160 ft. long. The tunnels pass under it as shown in the sketch, Fig. 61. Rectangular pits were sunk as shown by the drawing, there being 115 of these pits. Part of these pits supported the building directly; at other places the walls are supported on cross-girders over the tunnel, as indicated on the sketch. With the exception of part of the ground floor and basement the building has been continuously in use during the whole operation.

A method of underpinning was developed on Sec. 3 of Route 5 (see Fig. 42) by the Underpinning & Foundation Co., which consists essentially of the construction of a retaining-wall the face of which is practically at the neat line of the structure. This is made practicable by reason of the fact that along most of the route the space underneath the sidewalks is occupied by vaults used by the

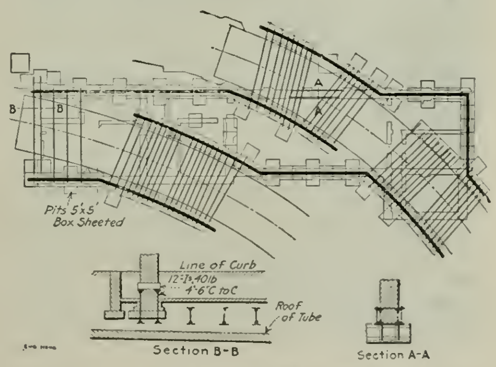

FIG. 61. LOCATION OF SUBWAY TUNNELS UNDER TRINITY PARISH HOUSE

owners of the adjacent buildings under revocable permits from the city. The width of the subway structure makes it necessary to occupy part of these vaults, though any remaining portion is afterward restored for the use of the abutting property owners. Most of the excavation of this section is in sand and the depth is comparatively shallow. The contractor, therefore, took advantage of the situation to build his sidewalls as retaining walls, working from the bottom of the vaults before commencing the main excavation. This effectually prevented any disturbance of the ground under the building and lessened the amount of timber, as no bracing for the sides was required. The retaining wall was built in sections by sinking 4 ft. square pits or wells (using the horizon-

[illegible] sheeting) separately, and some distance apart, then intermediate piles were put down and finally the whole closed up to make a continuous wall.

At the lower end of this section, the two middle tracks are depressed for the [illegible] St. connection, and as this is

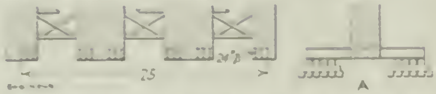

FIG. 62. UNDERPINNING WITH NEEDLES 6-STORY BUILDING, BROADWAY AND 115TH ST.

mostly below ground-water level and quite deep, the method above described did not wholly apply. It served, however, for the upper level and steel sheeting was then driven between the outer tracks and the inner pair, to enable these latter to be taken down to the required depth.

The six-story brick building at the corner of Broadway and 115th St. was held on needles while it was underpinned, and is a good example of what this method involves for a heavy building. The length of the front which was supported is about 25 ft., and eighteen 24-in. I-beams each about 25 ft. long were required to hold the weight. There were two piers between the corners and the three spaces between them were filled with heavy timber

FIG. 63. TEMPORARY SUPPORT FOR ELEVATED-RAILWAY COLUMNS

bracing and blocking before operations were commenced, as is shown in the sketch, Fig. 62. The I-beams were used in groups of three, supported on a continuous grillage [illegible] the [illegible] and on the [illegible] floor outside. Holes were cut one at a time in the sides of the columns to take the I-beams, and the whole load finally transferred to them while the foundations were carried down.

ELEVATED-RAILWAY COLUMNS

[illegible] of the elevated railway so [illegible] built were generally supported beneath the surface of the street on [illegible] footings, although the removal of which is made necessary by the construction of the subway. Temporary supports as shown in the photograph, Fig. 63, are

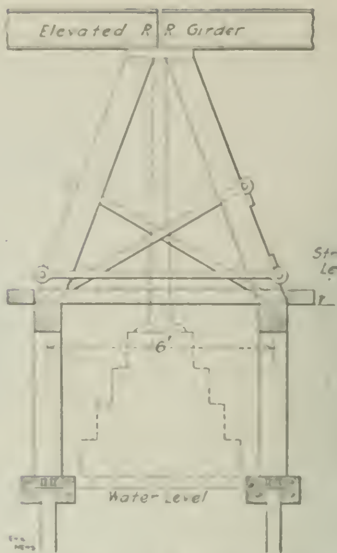

FIG. 64. SUPPORT OF ELEVATED-RAILWAY COLUMNS ON CHURCH ST.

built to hold the elevated structure during construction and considerable care is necessary to prevent any settlement and to provide as nearly as possible absolute safety.

On Sec. 1, Route 5, which is under Church St. and the Sixth Ave. Elevated, the A-frame supporting the cross girder above the column is supported on timber bents resting on steel piles. The spread brick footings are uncovered and spaces are cleared at the two sides of the structure to each of which three 14-in. steel piles are sunk to below subgrade and to a firm bearing; these are capped on each side by a reinforced-concrete beam on which a perpendicular timber bent is erected to about the level of the street surface as shown in the sketch, Fig. 64. These bents are about 18 ft. apart and an A-frame is then erected on them. The legs of the A-frame are held together by tie-bars and [illegible] timber bracing, as shown in Fig. 64. When the final support of the columns is to be below or at subgrade, clusters of hollow steel piles are driven and capped with reinforced concrete to form the new footing, as shown in the photograph, Fig. 65. In many cases, how-

FIG. 65. HOLLOW PIPES FOR FOOTING OF ELEVATED-RAILWAY COLUMN

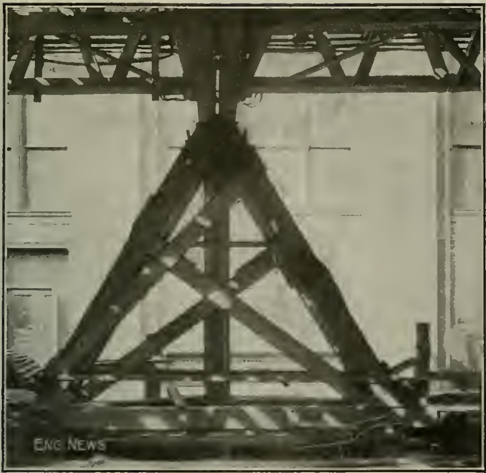

Fig. 66. Timber A-Frame with Eye-Bar Clamp Supporting Elevated-Railway Columns, Church St.

ever, the new column footings are carried directly on the roof of the completed subway structure.

The method of support adopted where the construction of a new sewer, on Third Ave., required temporary support of one pair of columns, is shown in the photograph, Fig. 66, the structure being blocked up from two pairs of girders laid direct on blocks on the paved surface of the street.

On West Broadway, at the lower end of the Seventh Ave.-Varick St. line, the elevated columns are supported above the street surface by a timber tower. Immediately below this and supporting it are two heavy 30-in. Bethlehem beams about 20 ft. long, laid on either side of the brick footing parallel to the street line. Both ends of these are in turn supported by a pair of 24-in. I-beams which rest on timber blocks on the ground outside of the brick footings.

A Year of the Commission-Manager Plan at Titusville, Penn.

By L. O. Bradley*

As the end of the first year under the commission-manager plan of city government draws to a close in Titusville, Penn., I cannot refrain from giving my full indorsement to the plan. At the start I was strongly opposed to it and fought it, but the results obtained in less than a year convince me I was in error.

In December, 1914, the commission form of government was installed, and as soon thereafter as possible, to perfect the ordinance, the city-manager plan was adopted, and City Engineer H. A. Holstein was appointed City Manager. By this action on the part of the council, the offices of street commissioner, water superintendent and city electrician were abolished, and all departments and employees placed under the personal supervision of the city manager, who at once proceeded to systematize the whole working force under one head.

A new method of time keeping has been installed, and all the purchasing of supplies is done by the manager, upon his written orders only, made out in duplicate, and all bills and payrolls pass through his hands before being paid.

In every department the buildings and equipment have been overhauled and repaired and brought up to an efficient working condition.

Street Department—New methods of cleaning the paved streets and working the unimproved streets were adopted, and laborers made to realize that working for the city meant the same as working for a corporation. The old flat rate of \$1.75 per day was dropped and laborers were paid 20c. per hr. for actual time employed.

In the street department the entire equipment has been put in good repair, at a small cost for new parts and materials. This was done by regular employees, in spare time, without additional help or cost.

Lighting Department—The equipment has been overhauled, all poles, wires and suspensions have been inspected, tested and renewed where needed, putting the entire system in first-class condition, ready for the installation of a new lighting system next year, which will be strictly up to date, increasing the efficiency and number of lights, at a reduction in operating expenses of about \$2500 per annum.

Water Department—This department has received like attention, and it is here, no doubt, the best results have been obtained. The manager, during the early spring, caused a complete inspection to be made of all services, connections and fixtures, resulting in a readjustment of the water rates throughout the city, putting them on a uniform basis, without favor to anyone, thereby increasing the revenue in the department about \$3000 per annum. No change of rates was made.

The service has been greatly improved, while the consumption of water has materially decreased. This is clearly demonstrated by the quantity of water in the wells, the reduction, by about two tons per day, of the coal consumed, and an increased pressure throughout the city.

After a systematic test of various kinds of coal, a better quality of coal has been obtained at a reduction of 11c. per ton. New lines have been installed, and leaks repaired continuously throughout the city.

Fire and Police Departments—These have been brought up to a high state of efficiency both as to men and equipment, and a new, modern police station is in process of construction, according to plans and specifications prepared by the city manager.

Finances—The present council came into office handicapped by a deficit of about \$2500, caused by the previous council overdrawing department funds, and further, by the loss of \$1200 in liquor license taxes, caused by the reduction of the number of licensed saloons in the city.

No increase was made in the tax levy, and it is now an assured fact that the finances of the city will show a balance on the right side of the ledger at the end of the fiscal year.

*Commissioner of Public Safety, Titusville, Penn.

Electric Lighting for Trains is to be adopted on all the lines of the State Railways of India, according to orders issued by the Government Railway Board. At present about 13,300 cars are lighted with Pintsch gas and about 5600 with electricity. It has been for some years the practice to equip all first, and second-class cars and all dining cars with electric lighting and electric fans, the latter being especially advantageous for the torrid climate.

A Comparison of the Economy of Powdered Coal, Oil and Water Gas for Heating Furnaces

By C. F. Herington*

Oil

Of the three fuels, powdered coal, oil and water gas, fuel oil has come into use far more than any other. The U. S. Navy yards have been consistent in their adoption of it. All now use fuel oil for heating operations, many to the complete exclusion of coal.

Without a doubt, fuel oil is one of the easiest of fuels to handle. It can be carried in pipes anywhere so long as there is air pressure or pump pressure behind it. It requires only a comparatively small outlay for equipment—all that is necessary is a couple of storage tanks, a pump to fill the storage tanks from the cars, a piping system to the furnaces, and means to secure the necessary pressure.

But fuel oil has one disadvantage—and this is considered by many to be a big one; the price is constantly going up. Ten years ago, fuel oil could be bought for $2\frac{1}{2}$c. a gal., and one could contract for any quantity at that price; now it is $4\frac{1}{2}$, 5 and $5\frac{1}{2}$c. a gal., and one has to take what quantities he can get at that price. Present conditions indicate that this advance in cost will continue beyond the limits of economy.

Powdered Coal

Steady increase in the price of oil has led, quite recently, to extensive experiments in the use of powdered coal and of water gas and producer gas as substitutes. As a fuel for burning under boilers, powdered coal may some time be a success. The use of powdered coal in portland-cement manufacture has proven very economical and here it has come to stay. But when it is claimed that it is equally good for various heating operations, such as welding, [illegible], annealing, riveting and forging, there is apt to be a difference of opinion.

In a recent article in an engineering paper, the following advantages were claimed for powdered coal:

(1) "Complete combustion, doing away with losses due to the carbon contained in the ash and in the escaping volatile matter." This is not correct, for if one stands for an hour watching one of these furnaces working, as the writer did, he will be completely covered with the unburned powdered coal which has escaped through the furnace doors. This has become such a nuisance to the surrounding [illegible] and [illegible] that attempts are now being made to relieve these conditions by placing a hood over the furnace door and connecting it into the furnace stack. This has not proven successful as yet, and probably will not until an exhaust fan is provided to discharge the unburned coal through the roof.

(2) "Total absence of smoke." Certainly this is not true outside of the stack, for powdered-coal furnaces, due to their [illegible] [illegible], smoke worse than oil. Powdered coal, as is well known, must be very fine to be [illegible], and, when pulverized and allowed to remain quiet for 48 hours, it cakes and requires that a man knock on the bins to loosen it. This tends to uneven combustion in the furnace, with large quantities of smoke when there is a large amount of coal coming through the burner, and no smoke when the coal is sticking back in the bins. No doubt this is largely due to inefficient handling of the feeder and burner; even so, a total absence of smoke cannot be claimed when such conditions are met.

(3) "A cheaper grade of coal may be used." The best coal for powdered fuel has a volatile content of not less than 30%, not more than 8% ash, and $1\frac{1}{2}$% sulphur. I think the readers will agree that coal meeting these specifications is of no very cheap grade.

Pulverized coal must be handled with great care, for if it is mixed with any quantity of air, it is highly explosive, as the records of accidents in cement plants will prove. In the January issue of the *Quarterly of the National Fire Protection Association*, the following appeared regarding the hazards of drying pulverized coal:

> Under no circumstances is it recommended that the products of combustion be allowed to come in contact with the coal to be dried. . . . Already there have been quite a number of accidents from this cause in which lives were lost.
>
> A characteristic coal mill explosion (March [illegible]) in New Village, N. J., at the Edison plant, killed six men and burned five others, perhaps fatally, besides injuring a score of others and destroying the coal building. It is supposed that the pulverized coal in the drier fired spontaneously and some of the burning fuel was carried by the automatic conveyor into the blower house. The atmosphere of the blower house being charged with coal dust, an explosion was the result.
>
> On August 19, [illegible], an explosion at the plant of the Nazareth Cement Co., Nazareth, Penn., caused a loss of $[illegible], while on November 28 of the same year $[illegible] damage was done to the Martin's Creek Portland Cement Co. (then known as William Krause Sons), Martin's Creek, Penn. The Dexter Cement Co., Nazareth, Penn., and the Alpha Portland Cement Mill No. 1, Alpha, N. J., had similar experiences the same year.

Another very serious objection to powdered coal, due to the incomplete combustion of all the coal injected into the furnace, is that this coal lies on the work, and when the work is taken out of the furnace, if not cleaned off, it is apt to be hammered into the work and make flaws which later are likely to be more or less serious according to the nature of the work. This is a fact seen from personal observation and cannot be denied.

Powdered coal is not good for small furnaces, as it requires too large a chamber for combustion, and from the experience of the users of powdered coal it is not desirable to have a combustion chamber separated by a bridge-wall from the working chamber. It is found that the trend of the users is to remove the bridge-wall and allow the powdered coal directly upon the work, which aggravates the condition mentioned above. If the large furnaces are changed from fuel oil to powdered coal, there still remain the small furnaces, and especially the portable ones, which will have to work on fuel oil. Then there would be the expense of handling two kinds of fuel where before there was but one.

The pulverizing plant is to be considered. When it is reported that [illegible] to perform a multitude of operations, I feel that [illegible] has not passed the doubtful points, as will be shown later on.

Gas

Greater familiarity and extended experience with natural gas for power and metallurgical purposes have led to better appreciation of the many advantages of gaseous fuel. It has emphasized the value of the gas producer for converting solid into gaseous fuels. But such conversion always involves a loss of a part of the energy of the coal; it is only because the gas can be utilized more

*[illegible], Brooklyn, N. Y.

efficiently that the duty obtained from it is greater than that given by the direct burning of the coal from which it is generated. Hence, any process which claims to deliver in the gas an amount of energy greater or even equal to that in the original fuel is a delusion or worse.

There are at present two kinds of made gases used for heating furnaces—producer and water gas. Industrially, producer gas is the combustible product of rather a complex series of physical and chemical changes induced in the fuel by the heat arising from its incomplete combustion in the producer. The combustion is termed incomplete not in the sense of leaving an unburned residue of carbon or coke, but because the combustible while completely gasified gives up only about 30% of its heat in primary combustion in the producer. The remaining 70% is developed when the gases are burned after leaving. Water gas is made by an intermittent process—first using an air blast to bring the fuel to high incandescence, then shutting off the air and forcing steam through the fire. During the air blow, a lean producer gas is made which may be enriched by the addition of water gas of a higher calorific value and used in the low-temperature furnaces or to drive gas engines. The true water gas is made during the steam blow, the steam being decomposed by the incandescent carbon so that its hydrogen is freed and its oxygen united with the carbon to form carbon monoxide.

The water gas can be used for all purposes where high temperatures must be secured without regeneration, as in factories carrying on a large variety of brazing, small forge, work, etc., where the furnaces are small and distributed over a large area. Temperatures ranging from 2500° F. to 2900° F. are easily obtainable with this gas, and with properly constructed furnaces it is possible to gain an added efficiency in operation so that the total B.t.u. in the gas used need be only 66 to 80% of the B.t.u. required in oil as used in approved oil furnaces for the same purposes. Water gas does not cause the metal forged to scale as does oil. and with gas it is possible to get a closer regulation of furnace temperatures.

Comparative Efficiencies

Now comes the debatable point of what is the efficiency of the furnace when using the different fuels. The powdered coal advocates will claim that the efficiency should be figured on the B.t.u. basis. That is, if a furnace burns say 22 gal. of oil to do a certain piece of work and each gallon contains 140,000 B.t.u., 3,000,000 B.t.u. in all, it will take 3,000,000 B.t.u. in coal to do the same work, but the coal is cheaper. If oil were 5c. a gal., it would take coal at $10 a ton to equal the cost; so the reader will perhaps agree that this is not the proper method of comparing efficiencies, any more than saying that the cost of gasoline per gallon is the operating cost of running an automobile.

The true way is to measure the efficiency of the furnace by the comparison of the input and output, and below are given results of some efficiency tests, made by the writer for a well known concern contemplating a revision of its furnace practice.

POWDERED COAL—(Furnace using preheated air for combustion).
Furnace cold at 60° F.
Steel and furnace heated to 2200° F.
Rise in temperature, 2140° F.
By test, 6.29 lb. of steel heated per pound of coal burned.
Specific heat of steel, 0.117.
0.117 × 2140 = 250 B.t.u. per lb. of steel.
250 B.t.u. × 6.29 = 1572 B.t.u. output.
1 lb. of coal = 14,000 B.t.u., input.

$$\text{Efficiency} = \frac{1572 \times 100}{14{,}000} = 11.3\%.$$

FUEL OIL—Same furnace with same rise in temperature and the same charge of work.
Heated 8.68 lb. of steel per pound of oil.
1 lb. of oil = 19,400 B.t.u., input.
250 B.t.u. × 8.68 = 2170 B.t.u., output.

$$\text{Efficiency} = \frac{2170 \times 100}{19{,}400} = 11.3\%.$$

WATER GAS—(Furnace using preheated air for combustion).
1 cu.ft. of gas = 300 B.t.u.
Specific heat of wrought iron = 0.113 (Kent).
Temperature rise from 1400° to 2500° = 1100° F.
Furnace charged with 3800 lb. iron.
To raise this iron to that temperature required 14,000 cu.ft. of gas.
0.113 × 1100 = 124 B.t.u.
3800 × 124 = 471,200 B.t.u., output.
14,000 × 300 = 4,200,000 B.t.u., input.

$$\text{Efficiency} = \frac{471{,}200 \times 100}{4{,}200{,}000} = 11.2\%.$$

Another furnace using fuel oil. (Not using preheated air).
Temperature rise from 1200° to 2200° = 1000° F.
Charge of wrought iron, 2150 lb.
Oil required, 22 gal.
2150 lb. × 113 B.t.u. = 242,950 B.t.u., output.
1 gal. oil = 140,000 B.t.u.
140,000 B.t.u. × 22 = 3,080,000 B.t.u., input.

$$\text{Efficiency} = \frac{242{,}950 \times 100}{3{,}080{,}000} = 7.88\%.$$

First Costs

In making comparison as to the relative first costs and operating costs with the three kinds of fuel, let us assume a plant now using fuel oil with a consumption of 50,000 gal. of oil per month at a cost of 5c. per gal., delivered at the shop. (These estimates were made for the company already mentioned.)

(1) FUEL OIL:

Cost of equipment (storage tanks in place, auxiliary pressure tanks in place, piping and fittings in place, steam connections, furnace connections, tank-car connections, tank pumps and air-blast outfit)	$21,100
Contractors' profit (15%)	3,165
	24,265
Engineering and contingencies (10%)	2,435
	26,700

(2) POWDERED COAL:

Pulverizing machinery, house, foundations, trestle and track, electric wiring, conveyors, walkways, motors, burners and controllers (30), furnace bins (30), furnace changes, hoods and connections, etc.	$68,100
Contractor's profit (15%)	9,900
	78,000
Engineering and contingencies (10%)	7,800
	85,800

(2A) FUEL OIL FOR SMALL FURNACES:

Tank in place, auxiliary tank in place, piping and fittings, furnace connections, tank-cars connections, pumps, air blast, etc.	$8,800
Contractor's profit (15%)	1,300
	10,100
Engineering and contingencies (10%)	1,000
	11,100

(3) WATER AND PRODUCER GAS PLANT:

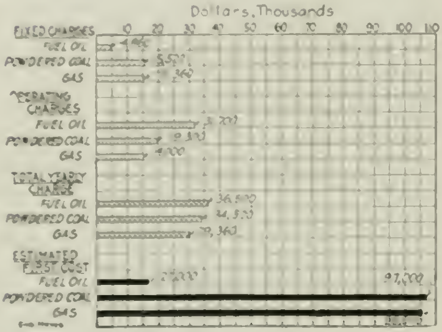
Gas-making machinery, building, trestle and siding, piping, furnace changes	$76,000
Contractor's profit (15%)	11,000
	87,000
Engineering and contingencies (10%)	8,700
	95,700

SUMMARY:

Fuel oil	$27,000
Powdered coal with fuel oil	97,000
Gas plant	96,000

Fuel Consumption of Plants

For the fuel-oil plant, at 50,000 gal. of oil per month and 140,000 B.t.u. per gal., 7,000,000 B.t.u. are consumed per month. If we allow 10 lb. of coal, at 14,000 B.t.u., equal to 1 gal. of oil, we have 500,000 lb. or 250 tons of coal used per month, for the powdered-coal plant. In addition, this plant consumes about 8000 gal. of oil, the difference being compensated for by coal required in drying the main fuel supply. For the gas plant, we require about 60,000 cu.ft. of water-gas per hour; at 20 cu.ft. per lb., we require 3000 lb. of coal per hour or 375 tons per month.



Diagrammatic Comparison of Estimated First Cost and Annual Charges of Coal, Oil and Gas Plants to Supply Fuel for 30 Furnaces

Total Costs

Now the total charges can be assembled.

FUEL OIL PLANT—(Estimated cost $27,000)

Fixed charges		
Interest (5%)	$1,350	
Depreciation (11%)	[illegible]	
Taxes and insurance (1%)	270	$4,860
Operation		
Oil ([illegible])	[illegible]	
Labor ([illegible])	[illegible]	
Electrical current, steam, etc.	[illegible]	
Miscellaneous supplies	[illegible]	[illegible]
Total yearly charge		$36,500

POWDERED COAL PLANT—(Estimated cost [illegible])

Fixed charges		
Interest (5%)	[illegible]	
Depreciation (10%)	[illegible]	
Taxes and insurance (1%)	[illegible]	[illegible]
Operation		
Coal ([illegible])	[illegible]	
Oil ([illegible])	[illegible]	
Labor ([illegible])	[illegible]	
Electricity ([illegible])	[illegible]	[illegible]
Total yearly charge		[illegible]

GAS PLANT—(Estimated cost $[illegible])

Fixed charges		
Interest (5%)	$[illegible]	
Depreciation ([illegible])	[illegible]	
Taxes and insurance (1%)	960	$[illegible]
Operation		
Coal (375 × [illegible] × 12)	$11,250	
Labor (1 operator, 2 [illegible])	[illegible]	
Water	744	$14,[illegible]
Total yearly charge		$29,[illegible]

These several figures are plotted on the accompanying diagram for easy comparison

A Heavy Cut for a Street at Kansas City

One of the municipal improvements around the new union station at Kansas City, Mo., is the extension of Main St. through the high bluff fronting the station, and this work has involved a very heavy cut, known to local engineers as the "Culebra Cut."

Construction

The improvement represents two stages of construction. An ordinance for the work as originally planned was passed in 1908, and a contract was awarded in 1910 for grading the street to 60 ft. width for a distance of 2450 ft. The work was accepted Aug. 27, 1913, and included the removal of 259,963 cu.yd. of earth, rock and shale at 74½c. per yd., or $194,347. Of the total quantity, about 70,000 yd. was due to caving and slippage. The earth removed was hauled about 800 ft. from the north end of the cut and used for filling low ground. The rock was crushed and sold.

Before this contract was completed, the Kansas City Terminal Ry. made some changes in the grade of the union station and enlarged the station plaza, making it necessary to lower the grade of Main St. about 8 ft. at the south line of 24th St. The company leveled to the new grade its property between 23d and 24th Sts. As soon as the first contract for grading Main St. was completed, it was necessary to let another contract cutting 8 ft. deeper at the north line of 24th St. and running out to the original grade at Grand Ave. It was also deemed advisable to widen Main St. from 60 ft. to 90 ft. The estimated quantity to be removed was 115,000 cu.yd. at 90½c. per yd. This contract extended over a distance of 1570 ft. and the cut is 90 ft. wide at the bottom, the maximum depth of cut being 82 ft.

This second contract is about 60% completed. There will be probably about 35,000 yd. of slippage on the sides, increasing the total quantity to 150,000 cu.yd., at a total of $141,[illegible]. The material is being excavated by steam shovels. At the north end a narrow-gage railway

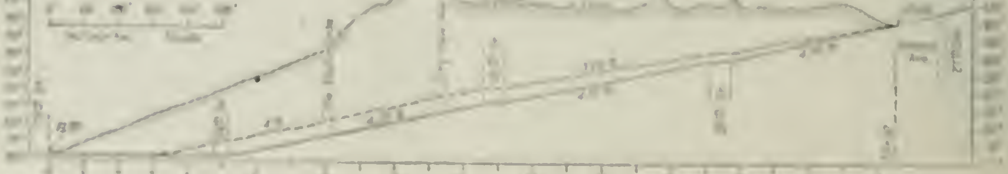


Fig. 1. Profile of Extension of Main St. through a Bluff or Ridge at Kansas City, Mo.

Fig. 2. Deep Cut for Main St., Kansas City, Looking South from the Esplanade

Fig. 3. Main St. Cut during Construction, Looking North at 26th St.

extending about 2000 ft. and crossing several city streets provides for making a fill in front of the city hospital grounds. At the south end, the material is being hauled by wagons to various places on neighboring property which is below grade. It is planned to install another narrow-gage railway south and west to 31st St., about 3000 ft., and to use the material for filling low property in that vicinity. It is expected that this grading will be completed by May, 1915.

The contract calls for cutting the sides vertical, but all slippage occurring before the work is finally completed must be removed, and the City Engineer has the power to order the contractor to remove any unsafe or overhanging ledges. The material is earth, solid rock and shale, and as about half the cut is shale and rock, the sides will stand on a slope of from ½ : 1 to 1 : 1. The contract is held by Spitzcaufsky Bros. All payments are by special tax bills.

The difficulties encountered included caving, and slides due to rain, the latter sometimes burying steam shovels and tracks. As no definite slopes are specified, the sides may be left as they stand at present, with the possibility of slides after heavy rains. Owners of property along the top of the cut must take care of their own property, having been paid damages. There was some trouble with the blasting, to avoid damage to buildings by the shocks as well as the throwing out of material. Difficulty was experienced in removing the excavated material promptly, as the narrow-gage track crosses several streets carrying heavy traffic, and its grades are steep for the dinkey locomotives, while the haul is rather long.

The city is planning to improve its property on the west side of Main St., between 24th and 25th St., as a park, terracing and grading down portions of it at an estimated total cost of about $350,000. The whole of this work will not be done at present, but it is expected that next year about $100,000 will be expended on this park. Some of the private property owners are already grading down their property and preparing to build. The city has started proceedings on the grading of the Esplanade from Grand Ave. to Main St., on which the maximum cut will be about 75 ft., at an estimated cost of about $60,000. It has not been decided what will be done with 25th St.

Assessments and Damages

For the first work on Main St., court proceedings resulted in an award of $49,117 as damages to abutting property on account of the cut. This amount was assessed against the frontage on Main St. between Ninth and 31st Sts., an arbitrary benefit district being fixed by the City Engineer and the City Council. This amount for damages went to the abutting property between the points to be graded, and the cost of grading was assessed against the property half way through the blocks on each side of the street between the points graded. The contractor received no pay until the work was entirely completed, and then was paid in special tax bills against the property.

The regrading and widening proceedings were sent to court and a verdict was returned Dec. 22, 1913, allowing the property owners between 24th St. and Grand Ave. an additional $32,350 for grading damages due to lowering of the old grade, and $11,265 for the 30 ft. of ground condemned (on the west side) in the widening proceedings. About 500 ft. of the ground taken in the widening was

from the Union Station Park, between 24th and 25th St., which is owned by the city, and for this the city received no pay.

These damages were assessed against a benefit district of the abutting property on Main St. between 12th and 35th St., 2¼ miles. Through a waiver of the property owners, the city was allowed to proceed immediately with the work, pending the collection of these benefits, and a contract was let and confirmed on Jan. 27, 1914. The total cost ($141,750), as in the first case, will be assessed half way through the blocks on each side of Main St. between 24th St. and Grand Ave., and special tax bills will be issued.

In the court proceedings outlined above, the property owners within the limits to be graded may submit evidence in court to a jury of six freeholders of the amount their property is damaged by cuts or fills. The jury views the ground, decides on the amount of damage each owner is entitled to, and spreads the total damages over the property in the benefit district. This is usually in the form of a graduated tax per front foot, decreasing as the distance from the work increases. A large part of the damages allowed are usually offset by benefits as the property abutting the portion to be graded is benefited as much or more than any other property in the benefit district when damages are not considered. The amounts given are the net amounts allowed as damages after benefits have been deducted.

For information as to the work described and the methods of assessment, etc., we are indebted to C. R. Mandigo, Assistant City Engineer of Kansas City, Mo.

Rail Failures and Train Accidents

The frequency of rail failures on American railways has been a source of trouble and anxiety for some years, but the fact that relatively few train accidents have been caused in this way has led to the impression that the conditions are not very serious in this respect. Inquiry shows, however, that the number of rail failures is very large and constitutes a serious problem, while the comparatively small number of accidents is due probably to careful watching and protection of the track. This matter has been discussed in our issues of Aug. 13 and Oct. 1, and we give below the results of inquiry as to the conditions on five leading railways. We have discussed the matter further in our editorial columns.

RAILWAY No. 1 (1800 miles)—During the calendar year 1912 this road had 1891 broken rails, of which 56 (or 3%) caused derailments. None of these derailments were serious.

RAILWAY No. 2 (3800 miles)—The statistics in Table I are for the calendar years 1912 and 1913. While none of the accidents resulted seriously, it must be borne in mind that any accident due to a broken rail is a serious matter.

TABLE I. RAIL FAILURES AND ACCIDENTS, RAILWAY No. 2

[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	Total
1912					
No. of rail failures	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
No. of broken rails	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
No. of derailments or accidents due to broken rails	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
1913					
No. of rail failures	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
No. of broken rails	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
No. of derailments or accidents due to broken rails	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

RAILWAY No. 3 (6500 miles)—Regarding derailments due to broken rails, an improvement in the quality of the rail, from a safety standpoint, will reduce the number of rails which break in service and (other things being equal) the number of derailments occasioned thereby. A comparatively small number of derailments due to broken rails may indicate that good rails are being used, but does not prove this, for the reason that the good results obtained may be due (in large degree) to the use of automatic block signals and high-grade maintenance-of-way methods resulting in detection and removal from the track of many rails which might have caused derailments.

In rail statistics, this road rates as "failed" not only rails that break but all rails that have developed defects of any character which would make their retention in the track unsafe. As their removal is a precautionary measure, in all probability many of these rails could have been continued in service for a much longer period without breakages, while others might have lasted indefinitely. The result of this practice is that the ratio of the so called rail failures to breakages is high, the actual proportion being unknown.

The number of rail failures recorded for the fiscal year ending June 30, 1913, is 1131. There were 11 derailments or accidents due to broken rails during the same period, with 12 passengers and employees injured (none killed), and slight damage to property. None of the accidents were serious. The following statistics for the same period are of interest in showing the very high degree of safety resulting from good rails combined with the use of signal systems and efficient maintenance methods. The statement includes both passenger and freight service.

Gross ton-miles per person injured due to broken rail	[illegible]
Gross ton-miles per derailment due to broken rail	[illegible]
Passengers and employees injured per derailment or accident of broken rail	[illegible]

RAILWAY No. 4—The statement in Table II shows the rail failures and accidents caused by rail failures for the six years from Oct. 31, 1907, to Oct. 31, 1913. Failures of rail of 70 lb. per yd. or less and failures in other than main tracks are not reported. All accidents resulting from rail failures are reported, including those on light rail and other than main tracks. The cost for damage to freight, equipment and track, and for clearing wreck, exceeded $150 in the case of five freight derailments in 1912 and two passenger and five freight derailments in 1913.

TABLE II. RAIL FAILURES AND TRAIN ACCIDENTS, RY. No. 4

Year	Failures	Derailments Due to Rail: Passenger	Freight	Total
1908	[illegible]	[illegible]	[illegible]	[illegible]
1909	[illegible]	[illegible]	[illegible]	[illegible]
1910	1749	[illegible]	[illegible]	[illegible]
1911	1882	[illegible]	11	14
1912	[illegible]	1	[illegible]	17
1913	[illegible]	[illegible]	[illegible]	[illegible]

RAILWAY No. 5 (1700 miles)—From Sept. 30, 1913, to Sept. 30, 1914, this road had a total of [illegible] broken rails, none of which resulted in a derailment or train accident of any kind.

An abstract of all the figures is given in Table III.

TABLE III. RAIL FAILURES AND TRAIN ACCIDENTS ON FIVE RAILWAYS

Road	Year	No. of Failed Rails or Rail Failures	No. of Derailments Due to Broken Rails	Rail Failures per Accident
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	11	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

* [illegible] † [illegible]

It will be noted that in this table a distinction is drawn between broken rails and rail failures, the latter including rails found to have defects of any character which make it necessary to remove the rails as unsafe. The figures relate to main-track only, and to rails of 70 lb. per yd. and upward. But in at least one case (No. 4) the accidents include those on lighter rail and tracks other than main track.

A notable development during the past few years has been the increasing use of openhearth rails. In regard to such rails, P. H. Dudley, Consulting Engineer for the New York Central Lines, says that the most important work now in hand is the production of basic openhearth rails in which the failures are reduced to a small fraction of those which occurred in the former bessemer rails. He states that the breakages which occur during cold weather are often due to the high tensile stresses from contraction before the rails give or slip in the splice bars, but such fractures rarely cause derailment, as the metal is not brittle and there is simply the fracture or open joint across the rail.

The basic openhearth rails on the above road include 519 miles of 80 lb., 530 miles of 100 lb. and 408 miles of 105 lb. Up to Sept. 1, 1914, the number of broken rails per 100 miles was 1.93 and 0.57 for the first two and none for the last. There was exceedingly cold weather last winter, and the results showed that the failures of the basic openhearth rails and the bessemer rails were as 1 to 22 under the same conditions of locality and traffic.

A New Cast-Steel Clamp for Guard-Rails

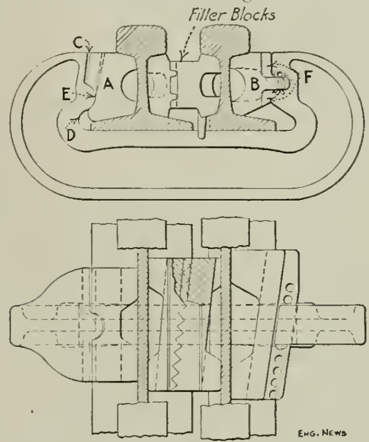
A recent design of guard-rail clamps, for maintaining frog guard-rails in proper relation to the adjacent running rails, is shown in the accompanying cut, and presents some special features. In general it consists of a heavy cast-steel yoke, with blocks and wedges between it and the rails and with filler blocks between the two rails. These latter blocks are wedge-shaped and with serrated contact faces, so as to be adjusted to give the desired width of throat or flangeway.

In fitting the clamp, the two filler blocks are first placed between the rails (being adjusted to the desired spacing), and the guard-rail is then spiked in place. The yoke is next placed and the outer block *A* inserted, and then the inner wedge *B* is inserted and driven home until the clamp is tight. This wedge is held from slacking back by means of a cotter pin and the block is secured in place by a rounded lug on the face of the yoke. The lug also holds the block firmly down upon the base of the rail. The filler blocks are prevented from slacking by means of a lug which engages the bottom of the yoke, as shown.

The yoke is of H-section, having heavy top and bottom flanges to reinforce the web. One of the principal features is the width of the end bearing outside the main rail, the purpose of this being to maintain the yoke at right angles to the rail.

The makers state that it has been found, in experimenting with such clamps, that even on well ballasted track the outer end of the clamp would move vertically, as wheels passed over the rail, causing the point of contact to shift. This would increase gradually, and with the point of contact at the top of the yoke *C*, there would be excessive stress at *D* tending to break or spread the yoke. To prevent this, the face now has the rounded projection *E* and a slight clearance at the top, so that the point of contact is permanently at this projection. The contact at the opposite end of the yoke is at *F*, with no contact against the rib through which the cotter pin is inserted.

The cast steel used is heat treated and has a tensile strength of about 72,000 lb. The weight of clamps complete for 80- to 100-lb. rails averages 50 to 55 lb. Two



A New Clamp for Frog Guard-Rails

clamps to each guard-rail are recommended for main-track service. These guard-rail clamps are in use on several railways. They are manufactured by the Reading Specialties Co., of Reading, Penn.

Resolutions of the International Irrigation Congress

Among the resolutions adopted by the International Irrigation Congress held at Calgary, Alberta, in October of this year, the following are reprinted as of interest to many of our readers:

IRRIGATION DISTRICTS—We recommend the passage by Congress of an act authorizing the Secretary of the Interior to enter into contracts with irrigation districts created under state law, by which the responsibility and control of each reclamation project arising from the Reclamation Act of June 17, 1902, may be turned over to an irrigation district organized under said law; and in the case of interstate projects, we recommend that suitable federal laws be enacted by which interstate irrigation districts may be formed; and in order that federal projects may be turned over to the land owners, as contemplated by the reclamation law, we recommend the careful revision and unification of irrigation district acts by the states of the arid regions, to the end that such projects may be turned over to the control of the settlers through such agency.

ENGINEERING EXAMINATIONS FOR FINANCIAL SAFEGUARDS—Full examination should be made by experienced engineers in the employ of the national, state and federal governments in advance of financing the construction of each large irrigation project, and that no such enterprise be entered upon by the governmental agencies unless it appears that such projects return at least 3% of the total investment for land and construction.

INTERSTATE WATERS—We hold that federal control as between those states which are not in full possession of their natural resources is essential to the equitable distribution and utilization of the waters of interstate streams.

RIVER REGULATION—We commend the efforts by the United States Congress to create a Board of River Regulation, and urge the enactment of suitable laws providing for

[illegible] river connections [illegible] at the head waters and [illegible].

WELFARE OF SETTLERS UNDER RECLAMATION PROJECTS.—We believe the United States Reclamation Service has been carrying out the purposes of the Reclamation Act in so far as the construction of engineering works is concerned. Experience has, however, demonstrated the expediency of extending to the Service additional authority to the end that it may promote, in other ways, the welfare of the settler upon the land.

STREAM-GAGING AND TOPOGRAPHIC SERVICE.—We urge upon the federal governments the necessity for more liberal appropriations for the work of topographic survey and stream-gaging work, and we urge stronger coöperation by the several states and provinces in making appropriations for this important work.

IRRIGATION SECURITIES.—We urge that the states of the arid regions assume their proper burden and legal responsibility for the purposes of the Carey Act, and state irrigation [illegible] and pass such laws as will assure the completion of all meritorious projects now undertaken.

Water Sedimentation, Coagulation and Mechanical Filtration at Waco, Texas

A water-purification plant of unusual completeness for one of its size was put in operation early in 1914 by the City of Waco, Tex. The plant consists of two 600,000-gal. open coagulating basins, giving 6 hr. of sedimentation for 6,000,000 gal. of daily filter capacity; four 1,500,000-gal. mechanical filter units; and a 1,000,000-gal. covered clear-water reservoir. The plant is constructed of reinforced concrete throughout, except that the building which covers a portion of it is of brick, with a tile roof. Among the special features are automatic steam control of the pumps which supply the purification works, electrically driven chemical solution agitators, Earl automatic chemical feed and automatic [illegible] rate controllers, and a steel wash-water tank, in which a uniform water level is maintained automatically. A general view of the pumping and purification plants is shown in the accompanying illustration.

The following description of the plant has been drawn (1) from notes sent to this journal by S. Werenskiold, Consulting Engineer, Dallas, Tex.; and (2) from a paper by F. B. Leopold, General Manager of the Pittsburgh Filter Manufacturing Co., Farmers Bank Bldg., Pittsburgh, Penn., prepared in the summer of 1913 for the annual convention of the Southwestern Water-Works Association.

For many years after about 1872, first one water company, then two companies, and then a consolidated water company supplied water to Waco. Finally, the works were bought by the city. Water was drawn from wells, which required supplementing by additional wells, air-lifts, etc., from time to time. In October, 1911, Mr. Werenskiold was called in by the Water Board to advise on obtaining an ample supply. In February, 1912, he recommended the Brazos River as a source, with mechanical filtration. In April, 1912, the city voted [illegible] for the new supply works, including the river connection, pump-well, pumping station and equipment, coagulating basins, filters and clear-water basin. In addition, $100,000 was voted for main extensions and a 125,000-gal. covered steel standpipe.

The intake and the short intake conduit are of reinforced concrete, as is the pump-well. The latter is elliptical in shape, 25x43 ft. in plan and 34 ft. deep.

Pumping Plant

The pumping plant is divided into two parts: (1) Two 6,000,000-gal. centrifugal pumps, for the low service, are driven by direct-connected vertical compound condensing engines, operating under a maximum head of 36 ft. and having a duty of over 50,000,000 ft.-lb. The steam pipe supplying these engines is provided with a diaphragm controlling valve automatically operated by the changing level of the sedimentation basins. The exhaust pipes from the low-service engines are connected with the extra large condensers of the high-service engines. (2) There are two 4,000,000- to 7,000,000-gal. cross-compound condensing pumping engines, for an average head of [illegible] ft. and having a duty of [illegible] ft.-lb. Both sets of pumps were furnished and erected by the Allis-Chalmers Manufacturing Co., Milwaukee, Wis.

Purification Works

General plans and specifications for the purification works were prepared by Mr. Werenskiold, and bidders were invited to submit detailed plans and corresponding prices. The contract was awarded to the Pittsburgh Filter Manufacturing Co.

Sedimentation Basin, Chemical or Head House, Wash-Water Tank and Pumping Station, Waco, Tex.

Mixing Chamber—As originally designed, the coagulants were to be introduced at the entrance to a mixing chamber of 150,000-gal. capacity. This chamber was 30x54 ft. in plan and 15 ft. deep, and was so divided as to have a waterway 16 ft. wide. Numerous vertical baffles were placed in this waterway. This worked well when the turbidity of the water was low, but, Mr. Werenskiold states, with high turbidities, sediment was deposited in the mixing chamber. The representative of the filter company therefore "removed nearly all the baffles, changed the point of application of the iron and lime to near where the water entered the distributing pipes and placed a baffle in front of these pipes, where they enter the sedimentation basins." By this means the "mixing chamber was practically converted into a small sedimentation basin, allowing nearly an hour for plain sedimentation, and thereby relieving the raw water from the heaviest sediment before the application of the chemicals," thus avoiding "the error of burying expensive chemicals in heavy mud, where the mud can be gotten rid of without cost."

Settling Basins—The two settling basins are 50x115 ft. in plan and 16 ft. deep, and can be operated singly, in parallel or in series, thus giving considerable flexibility.

The following description of the chemical-feed tanks and their control and of the filters and their operation and control is taken from the paper by Mr. Leopold, already mentioned:

The plant is designed for the use of lime and iron and hypochlorite, but alum can be used if desired. It has, however, so far been used with lime and iron and the results have proven most excellent with a turbidity of as great as 22,000 parts per million.

CHEMICAL TANKS AND REGULATING APPARATUS—The solution tanks consist of six tanks, or a pair of tanks for each solution, with dissolving boxes for mixing located on the second floor. Each tank is equipped with an electrically driven solution agitator, and the building is equipped with a hydraulic elevator for raising the coagulant from the first floor up to the storage room.

In the storage room there is a track with a traveler extending around the room and over the top of the solution tanks, so that the chemicals can be raised up to the traveler and carried in the required quantities over to the dissolving tank with the least amount of labor.

On the first floor is located the chemical-regulating apparatus. This consists of the Earl automatic controlling devices. Their function is to apply chemical solution automatically in proportion to the supply of water delivered to the coagulating basin. The apparatus consists of what is known as the master controller and the individual chemical controllers—one apparatus for each of the chemicals provided for.

The master controller is regulated by the velocity of the flow of water through the supply pipe to the coagulating basin, which, through a pilot and piezometer tube, builds up a head in the master controller corresponding to the quantity of water passing through the inlet pipe; and this head, of course, automatically changes with the quantity passing to the coagulating basin and is transferred from the master controller to the individual chemical controllers and in turn regulates, proportionately, the head of the chemical solution over the orifice feed, and in this way gives an absolute proportional feed of the chemical solutions to the quantity of water filtered.

While this apparatus is somewhat elaborate and costly, the economy in operation fully justifies its use, although in smaller plants it is not generally customary to install it. The same type of apparatus is in use in New Orleans, Minneapolis, Grand Rapids, Montreal and other places, but only in one other plant of the size of the Waco plant or anywhere nearly approaching it—that is at Fargo, N. D.

Each of the solution tanks is equipped with a recording gage which gives a definite record of the solutions that are used each day, thus giving a check on the operation of the plant also.

The solution apparatus being located directly over the inlet chamber, the supply line to the inlet chamber is extremely short and the usual troubles from this source are practically eliminated.

On the first floor is also located the laboratory, which is complete in its equipment, and up to the standard found in most of the larger plants in the country.

The filter building proper consists of a one-story building extension from the head house and the filters are four in number, two located on each side of a central gallery. They are equipped with hydraulic valves, operating tables and recording loss-of-head gages which give a record of the operation of the filters.

FILTER BEDS—The filter beds themselves are rectangular concrete units and are equipped with both air and water for washing purposes. Each bed is equipped with three wash troughs of a diamond shape, open at the top. The peculiar shape of this design is to prevent the loss of sand during the washing operation that occurs where a straight-side trough is used. The water is delivered into the filters from a conduit that is carried through between the two rows of filters and passes into an inlet chamber at one end and from there is distributed through the overflow troughs to the sand bed. It passes down through the sand bed in the usual manner and is carried out through the strainer system and through the effluent pipes into the gallery. Here it passes through the Earl type of automatic rate controller into the clear well.

RATE CONTROLLER—This rate controller provides against the filter operating to exceed its certain maximum rate, but within the maximum rate it automatically controls the filters to maintain a uniform level of water in the clear well; in other words, as the consumption decreases and the water level in the clear well rises, the filters are gradually closed off and the rate of flow decreased until when they arrive at a point where the maximum level of the water in the clear well is reached, they are completely closed off without attention from the operator. If the service pump then operates at a rate requiring the full capacity of the filters to supply them, the water gradually receding in the clear well, the filters are automatically and gradually opened to supply the increasing need until the limit of maximum flow is reached, which they are not allowed to exceed but which will be maintained until the consumption has so decreased again that the water level in the clear well gradually rises and again puts them under control. This is accomplished by a master controller which controls all of the individual rate controllers. This master controller is connected to the clear well and the difference in the level in the clear well is used to control the rate of filtration in the filter. The master controller operated by this head then in turn connects to each one of the individual rate controllers. There is also the advantage, if that is desired, that each individual filter-rate controller can be disconnected from the master controller and operated independently as a fixed-rate controller, or as an adjustable-rate controller, in this way giving the greatest flexibility of control of any apparatus that has so far been devised for this purpose.

It will be seen, therefore, that this plant is practically as nearly automatic in its control from the time the water enters the settling basin until it is taken out of the clear-water basin as it seems possible to devise. It is the only plant that the writer knows of so thoroughly equipped with automatic devices. Many of the larger plants have some of these devices but the writer knows of no plant that is completely equipped with them.

WASH-WATER TANK—For washing, a steel tank is used instead of the usual wash pump, for several reasons: One is, that under equal conditions the wash tank is preferable, as it gives a uniform pressure that is almost impossible to secure from a pump; another reason is that conditions here were hardly equal. The water could be supplied to the wash tank with the high-duty pump, probably a little more cheaply than it could be pumped with the ordinary centrifugal pump direct; also the clear-water well being located some little distance from the filter plant, pump connections would have been rather inconvenient and complicated to make. The wash tank is supplied automatically from the main. When filled, the supply pipe is closed. As the washing operation is started and the water level in the tank begins to recede, the supply valve is automatically opened and remains open until the water level in the tank again reaches its maximum level, when it is automatically cut off.

According to information from Mr. Werenskiold, the wash-water tank is a 50,000-gal. covered elevated steel structure, with its top 41 ft. above the filter-operating floor, and "is provided with a Golden-Anderson controlling-altitude valve to prevent overflowing."

W. M. Sleeper is Chairman and E. L. Fulkerson is Secretary of the Waco Water Board. S. J. Quay is Superintendent of Water-Works.

Construction of the Metcalf Ave. Sewer, Borough of the Bronx, New York City

By G. L. Christian*

The Metcalf Ave. sewer has a stormwater overflow into the Bronx River, while the dry-weather flow is carried to the White Plains Road sewer. The overflow starts immediately south of Randall Ave. This part is 9 ft. wide by 6 ft. high and 1300 ft. long, and has a capacity of about 355 cu.ft. per sec.; the capacity of the main sewer beyond this point is about 320 cu.ft. per sec.

The sewer is designed to carry the house sewage and the ... flow and a small percentage of the storm water, the major portion of the storm water being carried into the Bronx River by means of overflows, thus making it possible to construct a much smaller sewer than would otherwise be possible. The drainage area is 1290 acres.

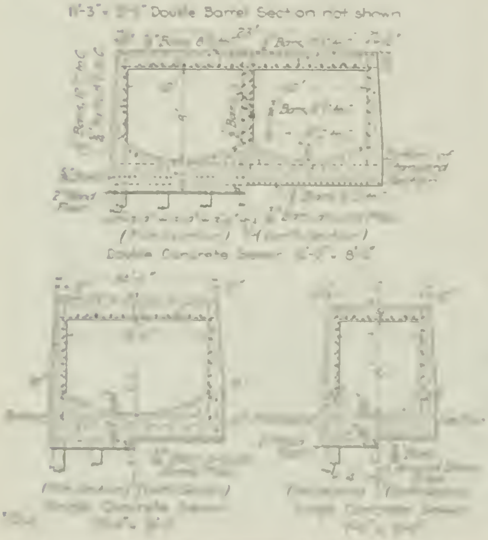


Fig. 1. Typical Cross-Sections of the Metcalf Ave. Sewer, Borough of the Bronx, New York City

The sewer is about 1 1/4 miles long, and is constructed of reinforced concrete throughout. The invert is uniformly 18 in. deep, the sides are perpendicular, and the roof flat. The interior height is 8 ft. throughout, the capacity of the sewer being regulated by increasing or decreasing the width. The center walls of the double sewer are all 12 in. thick, and the side walls of both double and single sewers are 18 in. thick at the springing line of the invert and 12 in. thick at the top of the wall.

Spurs are placed at a uniform height of 18 in. above the springing line of the invert and are spaced 10 ft. c. to c., except at street intersections, where there are none. The spurs enter the sewer at an angle of 60° and have their ends closed by a ... vitrified ... to prevent dirt from entering the sewer, while at the same time permitting ingress of ground water. Wherever they are more than 13 ft. below the grade of the street they are brought up to that height by means of risers incased in concrete.

The manholes are built on the side in single, and in the center in double sewers; in the latter the manholes have an opening, 2 ft. 8 in. in length, left in the center wall directly beneath the manhole opening.

Beginning at the northerly end of the sewer, with a width of 7 ft. and a height of 8 ft., the sewer widens at each street crossing until it attains a maximum width of 12 ft. 6 in. It then changes to two conduits 8 ft. 3 in.x8 ft. in cross-section. From this point it increases in width by steps to allow for the increased flow caused by the connecting lateral sewers until the overflow at Randall Ave. is reached, at which point the sewer consists of two conduits 11 ft. 3 in.x8 ft. in cross-section. South of Randall Ave., the sewer is reduced to a single 11 ft. 3 in.x8 ft. conduit. The excess flow is cared for by the overflow as noted. Fig. 1 shows some typical cross-sections.

Excavation—Over one-half the length of the sewer is built on a pile foundation, the trenches for which it has generally been found necessary to line with sheet piling, previous to excavating. The excavation was removed by clamshell buckets. In the dry earth and rock section the major part of the material was excavated by steam shovel.

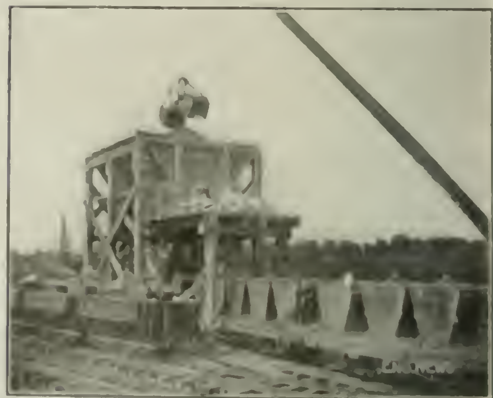

Fig. 2. Loading Buckets with Gravel, Sand and Cement from Hopper at Dock

Considerable water has been encountered and it was found necessary to install several steam pumps, with suction and ... discharge, as well as steam siphons and pulsometers. An electrically operated centrifugal pump has also been used.

Pile Foundation—In the pile-founded section, some of the piles are as long as 60 ft. below cutoff. The bents are 4 ft. c. to c., the piles in each bent being spaced from 2 ft. to 3 ft. c. to c. Halfway between the bents two batter piles are driven, one on each side of the sewer. The batter piles are securely fastened by a 3/4-in. steel bar, which encircles them and is embedded in the concrete surrounding them.

Two steam hammer pile drivers were used in driving the sheet and foundation piles, the guides for which were hinged near the top to allow them to be swung out of the vertical when driving the batter piles. The

*Assistant Engineer, Bureau of Sewers, Borough of the Bronx, New York City.

piledriver was carried on a platform spanning the trench, which traveled on a track laid with a rail on each side of the trench.

Contractor's Plant

Mixing and Placing Concrete—The contractor's plant for carrying on the work was a large one, and events have proved it to be ably designed and well

Fig. 3. Concrete Mixer and Concrete Distributing Chutes

fitted for carrying on rapidly and economically a vast amount of work with a minimum of friction. The monthly estimates of work done amounted to as high as $70,000.

At the inception of the work a dock was built at the mouth of the Bronx River adjoining the sewer outlet, upon which was erected and installed sand and gravel bins together with the necessary hoisting plant for unloading piles, steel bars, lumber, etc., and all plant and materials received for use on the different parts of the work.

A 3-ft. gage railway with 57-lb. rails, together with the necessary switches, was laid alongside the work for the whole length of the contract section. Three 18-ton locomotives are constantly engaged in transporting and distributing material along the different parts of the work. The contractor has his own cement boats, scows, etc., the use of which is made to dovetail into the scheme adopted for the mixing and placing of concrete, the net result being a large saving in money when compared with usual methods.

The cement, sand and gravel are handled but once, the *modus operandi* of which is as follows: The sand and gravel bins, together with a cement-storage platform, are located directly above the railway track and are continually fed from the boats by means of a stiff-leg derrick located on the dock. A locomotive drawing two flat-cars (Fig. 2), on each of which are seven bottom-dumping buckets, backs under the bins until the last bucket is under the gravel bin. A measure of gravel is admitted, after which the train is backed until the bucket containing the gravel is under the sand bin and the adjoining bucket is under the gravel bin, when the first bucket receives the required amount of sand while the second bucket is supplied with gravel. The bucket containing the gravel and sand is then backed under the cement platform and four bags of portland cement are emptied into it, each succeeding bucket being filled in the same manner until the fourteen are filled and the train pulls out to be followed by a similar train.

After loading, the train is hauled to whichever one of the concrete mixers happens to be at work. There are two concrete mixers, each of the Hains gravity type and mounted on a timber framework traveling on tracks alongside the trench (Fig. 3). The mixer framework has attached to it a skeleton steel tower 40 ft. high, within which is an elevator consisting of a one-batch bucket operated by a steam hoist located on the first floor of the supporting tower. Beyond this and traveling on the same track is a platform carrying a steam boiler, stiff-leg derrick and a hoisting engine.

The train carrying the fourteen buckets of gravel, sand and cement is run alongside and the buckets emptied one at a time into the upper pan of the mixer. The mixed concrete is emptied from the bottom pan into the bucket at the bottom of the steel elevator. From there the wet concrete is immediately hoisted to the top and automatically tipped and dumped into a hopper, running from which is a chute leading to the forms.

Each batch contains 0.78 cu.yd. of concrete and has at times, for a period covering several hours and with a haul of one-half mile, been deposited at the rate of a batch in 78 sec. Two of these mixers are installed on the work; only one is in use at a time. While the concrete is being deposited by one mixer, the forms are being prepared for concreting at the other, to which the concreting gang is transferred by means of the construction train, at the proper time. The mixers are moved when necessary by one of the locomotives, this operation requiring less than 10 min.

Fig. 4. Forms in Place for Bottom of Invert on a Pile Foundation

The sand and gravel are not moved by hand from the time they leave Cow Bay, Long Island, until they enter the forms as concrete, which requires spreading and spading. The total labor cost of unloading the sand, gravel and cement, transporting them about one mile, and

FIG. 5. REINFORCEMENT IN PLACE FOR LARGE DOUBLE-BARREL SEWER

mixing and depositing the concrete is about 75c. per cu. yd. Wood forms are used throughout. They are made in panels 12 ft. in length and have interior bracing as shown in Fig. 4.

CONCRETING THE PILE SECTION—The tops of the piles are cut to grade and the mud excavated to a sufficient depth to allow 2x4-in. waling pieces to be nailed on the sides of the piles, at right angles to the trench, and with their upper surfaces 12 in. below the pile tops, and a 2-in. flooring is laid thereon; the next step is to tie the batter piles together by fastening a ¾-in. corrugated steel bar around them (see Fig. 3), after which everything

FIG. 6. SEWER TRENCH UNDER CONSTRUCTION

FIG. 7. COMPLETED SECTION OF LARGE SEWER

is in readiness for the placing of the Class B (foundation) concrete.

The concrete is deposited to a depth of 18 in., completely encasing the pile heads and reaching to a height of 6 in. above the tops of the piles. Wooden invert profiles are next set at intervals of 15 ft., after which bars for the side walls and invert are placed.

The concrete is next deposited in alternate sections to within 1 in. of the finished invert surface, after which it is immediately covered with 1 in. of mortar and carefully screeded. After 48 hours the profiles are removed and the remaining sections filled with concrete. V-shaped keys are left at the ends of all unfinished sections and also in the top of the first section of side wall which forms part of the invert construction. These keys are for the purpose of forming a bond between the old and new work.

The province of the 6-in. wall is to have something against which the side forms may fit snugly, thus producing a good alignment and avoiding leakage of cement below the side forms while placing the concrete in the side walls. The forms for the side walls and roof are next set up, the steel bars for the roof put in place and properly fastened and the side walls and roof concreted in one operation.

In addition to the plant already referred to there are 8 dump cars, 28 four-cu.yd., two-way dump cars, 35 bottom-dumping concrete buckets, and two guy derricks, one being 75 ft. high.

The total cost of the work is about $569,000, and it is being done under the authority and direction of the Hon. Douglas Mathewson, President of the Borough of the Bronx; R. H. Gillespie is Chief Engineer of Sewers and Highways; Josiah H. Fitch, Engineer of Sewers, and the writer is Assistant Engineer, in charge of this piece of work. The contracting firm is Rodgers & Hagerty, Inc., for whom P. W. Rodgers is Superintendent.

The Water Filtration Hold-Up at Ottawa, Ont.

The long-standing water-supply muddle at Ottawa, Ont., bids fair to continue indefinitely unless the law courts again come to the aid of the city. This the courts have been invoked to do in a mandamus suit brought to compel the Ontario Board of Health to approve the latest plans for mechanical filtration of Ottawa River water, as prepared by Hazen & Whipple, of New York City.

Following projects for (1) a gravity supply from the McGregor Lakes in Quebec, (2) slow sand, and (3) mechanical filtration of the Ottawa River supply (all three after plans by Hazen & Whipple, New York City), there comes the Binnie and Houston (London, England) project for a gravity supply from Thirty-one Mile Lake, with its various dams and long steel pipe lines.* The latter was killed first by the courts and then by popular vote, the voters declaring for the Ottawa River supply, filtered.

Under a peculiar act of the Ontario legislature, dated Feb. 21, 1914, Ottawa was directed to secure plans for mechanical filters and to submit the plans to the Provincial Board of Health. If the board approved the plans, the city was authorized to borrow and expend $2,000,000 for their execution, and if the city council failed to pass the necessary by-laws to that end, then the board was authorized to build the works. The act also provided that in case of nonapproval of the plans for mechanical filtration by the board, then the city should at once proceed to carry out the Binnie and Houston plans for the Thirty-one Mile Lake project, with authority to borrow $8,000,000 for the purpose. A further proviso authorized the board to execute this project in case the city authorities failed to.

On Sept. 18, 1914, the Provincial Board of Health of Ontario unanimously disapproved the recently prepared Hazen & Whipple plans for mechanical filters, thus:

> The Ottawa River is beyond any question a polluted source of supply at all points in the vicinity of the City of Ottawa. The character of this pollution was pointed out in the report of Nov. 25, 1911, made by Allen Hazen and others, as well as in other reports of later date made by the said gentleman and others, and all experts agree that the danger of pollution is continually increasing. The fact that it is an interprovincial stream renders the control of its pollution all the more difficult.
>
> The board understands it to be a fact that the people of Ottawa have been led to believe that treatment of the Ottawa River water by mechanical filtration will relieve them of the further use of hypochlorite of lime. In reference to this question, Mr. Hazen, in his statement before the board, said that chlorination would be constantly required and that the use of chlorine as well as the administration of chemicals and control of the plant must at all times be under the most careful and unremitting expert supervision.
>
> While the board is sensible of the value of the chlorination of polluted water as an emergency measure, despite the objectionable taste usually associated with its administration, it feels that it would not be doing its duty to the citizens of Ottawa or to the general public of Canada, who may have occasion to visit the Capital City, by countenancing the use of a water which, after mechanical filtration, constantly requires chlorination, when a pure and adequate supply requiring no treatment whatever may be readily procured.

This action was all the more remarkable because a few years ago the board ordered the city to install a mechanical-filtration plant (plans were made by Hazen & Whipple, but the project was defeated at a popular election in January, 1914); and also because since that date the board has approved plans for mechanical filters ("drifting sand" filters; ENGINEERING NEWS, June 25, 1914) for Toronto.

Under date of Sept. 21, 1914, Allen Hazen wired to Taylor McVeity, Mayor of Ottawa, as follows:

> Rejection of plans by Provincial Board of Health seems to turn on my statements regarding hypochlorite. These statements are used in a way which I consider unwarranted. Under the proposed plan the present objectionable use of hypochlorite would cease. I stated to the Provincial Board that good water would be obtained without hypochlorite but that the use of a small amount, perhaps one tenth that now used, or its equivalent in liquid chlorine or other agent, might be desirable. Such quantity is used in most public water-supplies at the present time from even the best sources, and is unobjectionable. Plans do not differ in this respect from those previously approved by the board and present conditions do not warrant a reversal of former action.

The Thirty-one Mile Lake, or Binnie-Houston project, was approved some time ago by the Provincial Board of Health. In the board's memorandum of Sept. 18, 1914, disapproving the mechanical-filtration project, the Binnie-Houston project was spoken of as "one which provides for a supply of unquestionably pure water from a source and in a manner preëminently satisfactory to the board."

Interesting opposition arguments on the Thirty-one Mile Lake project were presented in a letter "from John Murphy, C.E.," of Toronto, dated Sept. 21, 1914, and sent by Mayor McVeity to the city council of Ottawa:

> Was the Ontario Board of Health's decision regarding Ottawa's Water Supply made with the knowledge of the following facts?
>
> The level of Thirty-One-Mile Lake must be raised 24 ft. before it reaches the top of the divide which now prevents it from flowing toward Ottawa.
>
> It will rise to this level, according to Binnie, in 5 or 6 years if 37 in. of rain falls annually. But Ottawa's average rainfall for 40 years is less than 32 in.
>
> Not a single drop of the water which is now in Thirty-One-Mile Lake or of the water that would be in it and the country flooded by it when the level reached the 24-ft. mark above referred to can ever flow to Ottawa. It is only the overflow above this 24-ft. level which can cross the divide and flow toward Ottawa; and yet those who, like the Ontario Board of Health, are bound to force the Thirty-One-Mile Lake scheme on us want the public to believe that all that need be done to get water into Ottawa from Thirty-One-Mile Lake is to tap it with a pipe line.

Even if the court sustains the Provincial Board of Health in its attempt to force Ottawa to go to Thirty-one Mile Lake for a gravity supply, it seems unlikely that the city will be able to finance an $8,000,000 water-supply project for some time to come. A $2,000,000 bond issue for mechanical filters might be taken up locally.

*See "Engineering News," Apr. 9, 1914, pp. 808-9, for review of all the projects, and Nov. 20, 1913, for an account of the Binnie-Houston project.

Field and Office

Concrete-Road Building with Small Concrete Mixers

A rather remarkable record was made during the past summer in concrete-road building in Centralia, Wash., by the use of two very small, cheap, concrete mixers and a force of 16 men.

THE MIXERS—The mixer is known as the "Archer" mixer* and the two units cost a total of only $530. The mixer is of the batch type and consists of a cylindrical drum, on top of which is a small gasoline engine geared direct to the teeth on the outside of the drum. The whole is mounted on a light wheelbarrow-shaped frame, which can be moved by a couple of men. Each mixer has a capacity of 4½ cu.ft. of wet concrete per batch.

METHODS—The road was a two-course concrete pavement 18 ft. wide. The bottom course, 3½ in. thick, was a 1:3:6 gravel concrete and the wearing course, 3½ in. thick, was a 1:2:4 pea gravel concrete.

CONCRETE-ROAD BUILDING AT CENTRALIA, WASH., WITH SMALL CONCRETE MIXERS. AVERAGE PROGRESS 571 SQ.YD. PER DAY

Sixteen men were employed—5 men laying concrete (2 spreaders, 2 tampers, 1 finisher), 1 man tending the machines with cement, 1 man tending the machines with water, 3 men loading and wheeling sand, 4 men loading and wheeling gravel, and 1 man delivering cement to both machines.

Temporary spouts, 7 ft. long and swung from a chain extending from the frame of the machine to the discharge end of the spout, were added to the regular equipment of the mixers. This gave the machines sufficient reach to cover the width of the road, and enough fall from the base to deposit the top course, without any handling of the wet concrete except in spreading.

COST DATA—Fourteen men received $2.50 per day of 8 hr., two men received $3 per day. One mile of concrete road was constructed in 18½ working days. The labor cost was $758.50, or 37c. per cu.yd. of concrete. This does not include the salary of a general foreman, who, in this instance, was the contractor. For the entire 18½ days the average progress was 571 sq.yd. per 8-hr. day. The contractor was J. W. Phifer, of Centralia, Wash.

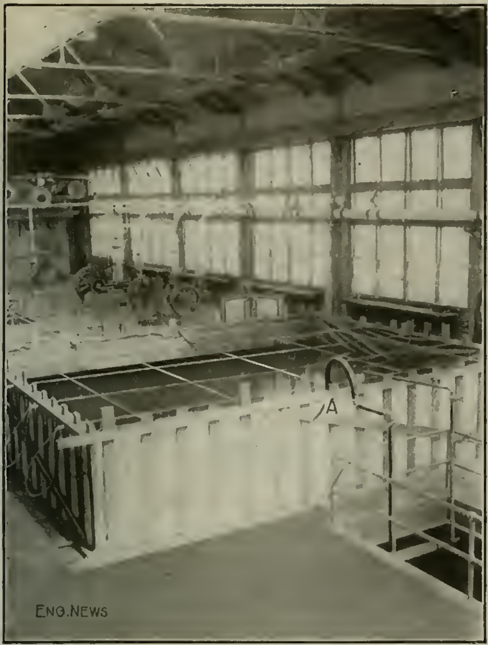
*Made by the Archer Iron Works, Chicago, Ill.

Using Water as Load in a Floor Test

By F. R. McMillan*

The readers of ENGINEERING NEWS may be interested in the accompanying photographs showing a method of applying a test load to a floor slab of a building. The framework shown consists of 4x4 horizontal timbers with 2x6 verticals bolted every 18 in. Each of the four sides is bolted up into a single section, with sway-bracing to prevent sidewise collapse. The opposite sides are tied together top and bottom by light hoisting cables. These pass through the 4x4 horizontal timbers and are secured at the ends by ordinary guy-wire clamps. The lining consists of two sheets, the outer one of plain 12-oz. canvas and the inner one a special rubberized canvas of about the same weight. These sheets are made up square, with eyelets spaced 18 in. on all edges, through which hooks or nails are driven into the verticals of the frame. The corners are made by simply folding one side back on the other.

*Department of Experimental Engineering, University of Minnesota, Minneapolis, Minn.



Canvas Water-Tank for Load Test of Floor

The view shows the test of a 20x24-ft. panel of the Experimental Engineering Building, College of Engineering, University of Minnesota, where the water was carried to a depth of 4 ft., making a live-load of 250 lb. per sq.ft. This maximum load was kept in place for only a few hours. A depth of 3 ft. was in place for two days, after which it was decreased to 2 ft. and left for 72 days longer. No leaks developed in this length of time, but on removing the load it was found that considerable water had collected between the two sheets and between the outside canvas and the floor.

At the end of the test, the canvas was still in serviceable condition, but would hardly permit of another load as great as 4 ft. For loads up to 175 lb. per square foot and where it is not desired to keep the load long in place, the canvas sheet could be used repeatedly.

At the point marked *A* will be observed a gooseneck of 3-in. pipe, which was used as a siphon to remove the water. The siphon would remove all the water but about 2 in. Near-by will be seen a 1½-in. pipe and valve connecting with the city main, through which the water was supplied.

The water loading proved very convenient in this instance, as it was desired to remove and reapply the load a number of times. While the method presents some disadvantages, such as the impossibility of obtaining extensometer measurements or examining the slab at points on the upper surface within the loaded area, it can be used with great economy under many conditions. The cost of erecting and removing the framework is not great, the big items of expense being the cost of the rubberized canvas (about $1 per sq.yd.) and the depreciation. Where water connections and a satisfactory means of draining the water can be arranged, the test with water costs less than other loading materials. With a meter rate of 60c. per M cu.ft., the cost of the water wasted is only 2c. per ton.

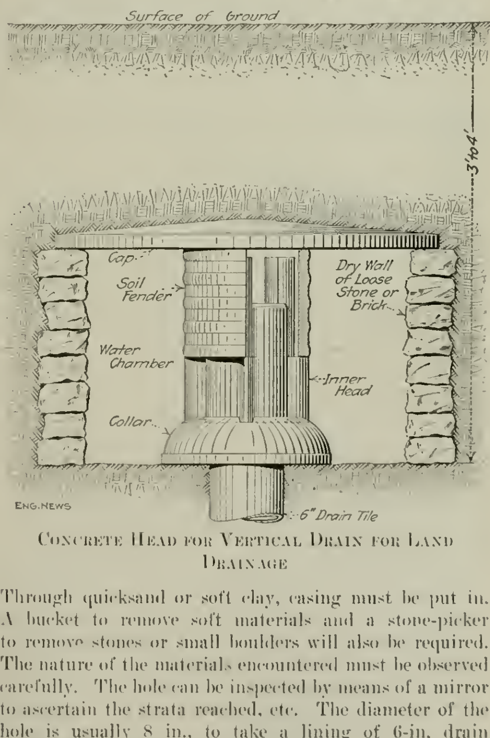
This method was suggested by F. C. Shenehon, Dean of the College of Engineering, University of Minnesota, and was first used in March, 1913.

Draining Land by Wells; Concrete Drain Head

Draining agricultural and swamp lands by wells or vertical drains—instead of by ditches and horizontal lines of tile—has been done successfully in a number of cases throughout the Central states. The wells are sunk to reach underflow strata that will absorb or carry off water readily. Success depends largely upon proper knowledge of the geological conditions, and results are problematical when the drain-wells are sunk at random.

The depth of wells is said to range from 20 to 45 ft. It is claimed that one well will drain from ½ to ¾ acre.

The wells are drilled with augers, pipe extensions being added to the shaft of the auger as the depth increases.



Concrete Head for Vertical Drain for Land Drainage

Through quicksand or soft clay, casing must be put in. A bucket to remove soft materials and a stone-picker to remove stones or small boulders will also be required. The nature of the materials encountered must be observed carefully. The hole can be inspected by means of a mirror to ascertain the strata reached, etc. The diameter of the hole is usually 8 in., to take a lining of 6-in. drain tile.

The drainage is taken from the soil, surface water being excluded. For this purpose special drain heads are made, which prevent the water from carrying soil into the pipe. A patented concrete drain head, made by the American Drainage Co., Dubuque, Iowa, is sketched herewith. The top of the drain pipe is 3 or 4 ft. below the surface of the ground, and above it the ground is excavated to a diameter of about 3½ ft., the lowest part of this hole

[illegible] lined with stones or old brick to form a water chamber. Upon the [illegible] drain pipe is placed a collar, and this supports a grooved inner head surrounded by a [illegible] or [illegible] header. The chamber is roofed with a cap slab. After these parts have been assembled, the ground is filled in above the cap. When the ground becomes wet, the water seeps into the chamber and siphons up under the header, flowing over the top of the grooved inner head into the vertical drain.

Handling Construction Material by Aerial Tramways

The use of aerial tramways for handling construction material is an interesting feature in the construction of the buildings for the new state penitentiary at Bellefonte, Penn., near the Rockview station of the Bellefonte & Snowshoe Branch of the Pennsylvania R.R. The first building, now being erected, is of reinforced-concrete, 25?x?0 ft., with three stories for the central portion and one story for the wings. This is located at about the highest point of the site. It is probable that the entire work will extend over several years.

The stone for the concrete is obtained from a limestone quarry [illegible] mile north of the site, the stone being crushed to [illegible]-in. size at the quarry. The sand or finer aggregate is obtained by crushing and pulverizing field stone, which is very plentiful in the valley along the railway. The pulverizer is located about 1000 ft. south of the building site. In view of these conditions and of the long period of time which the work will cover, it was decided to use aerial tramways for handling the materials. A plan of the plant is given in Fig. 1. At the building site a storage bin was erected [illegible] ft., and 10 ft. deep, so divided as to give a capacity for 130 cu.yd. of stone and [illegible] cu.yd. of sand. Both tramways enter at the top of the structure and dump the materials automatically into the bin. The materials are drawn off through chutes into small cars, which are pushed by hand to the mixer plant. The concrete is handled by an elevator tower and inclined chutes.

The tramways are of two different types. The one for limestone is of the endless type, having a number of traveling buckets which are suspended from trucks running on fixed track ropes and permanently attached to a continuously running traction rope. The carrying capacity is 10 tons per hour with ten buckets of 6-cu.ft. capacity (or 600 lb. of stone), but this will be increased later by attaching additional buckets. There are eight spans, 250 to 460 ft. long.

Of the two parallel track ropes, the one for the loaded buckets is $1\frac{1}{8}$ in. diameter, while that for the empty buckets is $\frac{7}{8}$ in. The endless traction rope is $\frac{9}{16}$ in. diameter, and its driving pulley at the lower terminal is driven by a 10-hp. engine. A friction clutch provides for stopping the rope without stopping the engine. This rope has a speed of 300 ft. per min. The stone from the crusher is carried by a belt conveyor to a bin of 90-cu.yd. capacity. By means of an automatic loader, shown in Fig. 2, the buckets are filled while in motion and are not detached from the hauling rope.

As the amount of sand to be conveyed is only about half the amount of stone, while the length of haul is considerably less, a two-bucket or alternating tramway was adopted for carrying this material. This tramway has considerable rise and is so arranged that the buckets will clear the wall of the penitentiary if that should be built while the tramway is in service. It has two spans of 350 and 630 ft., with $1\frac{1}{8}$- and 1-in. track ropes and a $\frac{5}{8}$-in. traction rope with two buckets of [illegible]-cu.ft. capacity. This rope is driven by a 10-hp. engine and runs at a speed of about 450 ft. per min.

The use of a larger rope on one side is due to the fact that the tramway carries lumber and reinforcing steel,

FIG. 2. [illegible] TERMINALS OF THE AERIAL TRAMWAYS

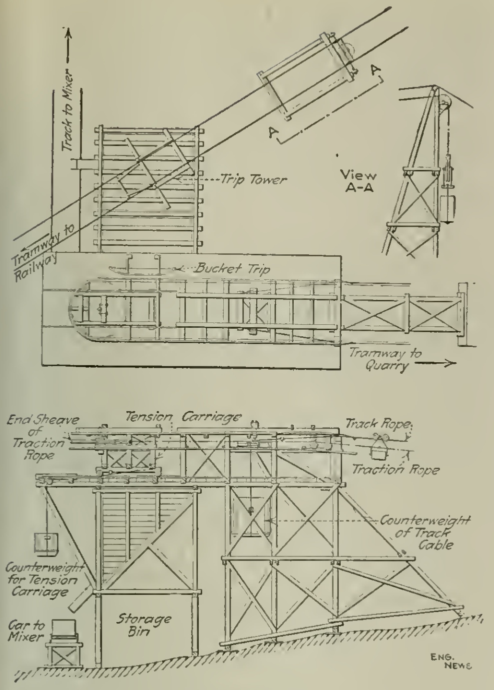

Fig. 3. Upper or Discharging Terminals of the Aerial Tramways

and that these materials are handled on this side only, to avoid complications at the terminals. These materials are loaded and unloaded by hand. The sand or pulverized stone is fed by an elevating bucket conveyor to a small bin, from which it is fed to the buckets by special chutes (Fig. 2).

Both tramways discharge automatically into the storage bin near the buildings, and their upper terminals are shown in Fig. 3. The two tramways are used in series for carrying coal from the railway to the quarry. The elevations above sea level are about as follows: Railway siding, 1014 ft.; rail of lower tramway terminal, 1018 ft.; track ropes of both tramways at bin at upper terminal, 1140 ft. (40 ft. above the ground); rail of tramway terminal at quarry, 1029 ft. The ropes of the limestone tramway are at an average height of 20 ft. from the ground.

The tramways, with their bins and loading devices, were built by the A. Leschen & Sons Rope Co., of St. Louis, Mo.

Notes on Errors in Survey Work

By A. W. Bedell*

Cumulative errors should always be recognized as such and carefully avoided. Personal errors are often of this kind. To illustrate, the vibration of a plumb-bob string will be compensative, but if a chainman habitually stands so that his eye will project the point of the bob to the ground obliquely, the error from this will be cumulative.

If a chain is out of alignment by an amount d in a length l, the error in distance from this will be

$$e = \frac{d^2}{2l}, \text{ nearly}$$

This error is of little importance on long tapes, but it is cumulative.

It is also worth while to notice that a transit should be centered more carefully in one direction than in another (see Engineering News, Jan. 22, 1914, p. 195).

Very often it is required to know what error of closure is to be expected, consistent with the accuracy of the work done. The usual way of designating errors of closure, as 1:3000, etc., is misleading, for the degree of error does not bear a constant relation to the distance. The same accuracy of work which would produce an error of 1 ft. in 3000 ft. would result in an error of $\sqrt{2}$ in measuring 6000 ft., which is 1.4 ft. in 3000 ft.

Since most errors vary with the square root of the distance and since areas vary with the square of the distance, the closing error may be expected to increase with the fourth root of the area. But if the work includes many cumulative errors, it will vary more nearly with the square root of the area.

If the angular error in a course AB is represented by a, which results in a distance y at the end of the course, and if x is the error in distance, the resultant of these is the error of closure e. If the course AB were long enough to continue around the traverse and close upon itself, the total value of e would be the error of closure of the survey.

If the probable angular error (in feet) per 100 ft. is taken as y_1, the probable lineal error per 100 ft. as x_1, n as the average length of a course (in 100-ft. chains), m as the number of courses, and l as the total traverse in chains, equal to mn, then for the whole survey

$$y = ny_1\sqrt{m}$$
$$x = x_1\sqrt{mn}$$

and the error of closure

$$e = \sqrt{x^2 + y^2} = \sqrt{lny_1^2 + lx_1^2}$$

On a transit reading to minutes y_1 will be about 0.01 or 0.02, and according to the skill of the chainman, x_1 will be between 0.01 and 0.10. It will be noticed from the first equation that by increasing the number of courses, the error y will decrease somewhat, for it accumulates on a single course, and it is partially compensated as the number of courses is increased—within limits. This formula is applicable only for compensative errors.

When a measurement is made to the nearest unit of any kind, and made accurately, the probable error (from this source) of a single reading is not one division, but a quarter of one division. The greatest error possible would be half a division, and the mean of all errors from zero to a half would be a quarter division. Using large units, therefore, is not inconsistent with accuracy, providing instrumental errors are small.

It may easily be demonstrated that leveling can be done by reading the rod only to tenths, and with 25 sights to the mile, with an error of $\frac{1}{4}$ of $0.1 \times \sqrt{25} = 1\frac{1}{4}$ tenths. It may be added that for many purposes it is well to use larger divisions, as tenths of feet on rods and

*Chappaqua, N. Y.

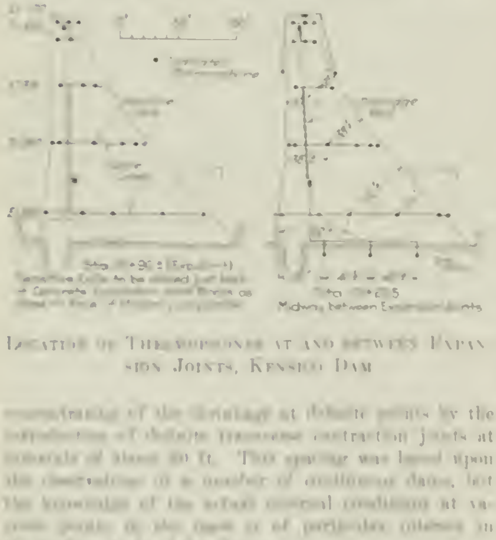
spaces, and to subdivide these to hundredths of feet by estimation with the eye only. Those who have never tried this method will be surprised at the accuracy with which work can be done. The average surveyor with ordinary practice can subdivide a unit into tenths with a mean error of about half a tenth or less. The absence of many small graduations is certainly less confusing.

Thermophones in Kensico Dam

By Wilson Fitch Smith*

A number of thermophones have been placed in various positions in Kensico Dam on the new Catskill Aqueduct for New York City for the purpose of determining the variations in temperature in the body of the masonry as an aid to the study of the stresses resulting from the expansion and contraction of the mass due to temperature changes.

In order to obviate the unsightly cracks which occur at irregular intervals in all large continuous masses of masonry the design for Kensico Dam provides for the



Location of Thermophones at and between Expansion Joints, Kensico Dam

concentration of the shrinkage at definite points by the introduction of definite transverse contraction joints at intervals of about 80 ft. This spacing was based upon the observations of a number of continuous dams, but the knowledge of the actual internal conditions at various points in the mass is of particular interest in the further study of this design.

Variation in temperature in a large mass of concrete masonry is of two kinds: first, a sudden rise of many degrees due to the heat given off by the cement in the chemical process of setting, followed by a gradual fall due to the radiation and dissipation of this heat, and secondly, the gradual changes due to the daily and seasonal changes of atmospheric temperature.

The thermophone consists essentially of two coils of fine wire of metals having different coefficients of electrical conductivity under varying temperatures. In this case, the two coils are of german silver and copper wires and are connected in circuit. The coils are contained in a closed brass tube 1½ in. in diameter and 8 in. long. The three connecting wires are No. 16 insulated copper enclosed in a special insulating wrapping and incased in a heavy lead covering. The lead covering of the connecting cable is soldered tight to the brass tube.

The thermophones are placed in the dam in two groups, as shown in the accompanying figure. One group is in a vertical plane in the center of a section midway between contraction joints, the other is near the face of one of the joints with a view to showing the result of building up one section of the dam in advance of the adjoining section. Owing to the remarkably rapid progress made in the construction of the dam, no marked difference has been shown.

The cables lead through the masonry to the nearest inspection well and thence to the inspection galleries, where terminal boards and dial switches afford easy means of connection to the indicating instrument. This consists of a Wheatstone bridge, galvanometer and battery. The pointer of the resistance bar on the Wheatstone bridge moves over a scale graduated to read degrees F. so calibrated that when the resistances in the two sides are balanced, as indicated by the galvanometer, the temperature of the thermophone is indicated on the scale. Each thermophone was compared with a standard thermometer before it was placed.

The lower thermophones were placed in the late fall of 1913, those at El. 260 and El. 315 during the present season and those at the top of the dam will probably go in this fall.

It is too early yet to draw complete conclusions from the observations as to the effect of atmospheric changes because of the influence of the new masonry as it is added, but one interesting fact has been clearly demonstrated at several different points in the center of the dam, which is that the setting of the concrete causes a rise of 40° in the mass, the maximum occurring in from 7 to 28 days, the cooler the air the slower the rise in temperature.

This result was most clearly demonstrated in the center of a mass of cyclopean masonry, 80 ft. square with 8 ft. below and 19 ft. above the thermophone, all placed within a period of six days. The concrete is of the proportions of 1:9 with from 25% to 30% large stones in the mass.

*Division Engineer, Headquarters Aqueduct Department, Board of Water Supply, City of New York, Valhalla, N. Y.

Earth Embankment and Fill at Shopton, Iowa*

The construction of the Keokuk dam, with a consequent rise of the Mississippi River back of the dam, necessitated quite extensive fill work at the Shopton yards and shops of the Atchison, Topeka & Santa Fe Ry., two miles west of Fort Madison, Iowa. The backwater above the dam formed a lake at Fort Madison 1½ mi. wide and 8 ft. deep.

The elevation of the Santa Fe yards was 518. On Jan. 1, 1913, before the final rise in level, the elevation of the river was 522.00. The Mississippi River Power Co. guarantees that the maximum level will not exceed, in flood times, an elevation of 528. It is expected, however, that the normal elevation will be 525. Before the construction of the dam, the elevation was 510 to 518.

The whole work may be divided into the following elements: Grading and trimming for a new embankment, raising the yard, track and buildings and filling

*Data for this article were furnished by William B. Bush, Engineer, Atchison, Topeka & Santa Fe Ry., Fort Madison, Iowa.

in under and around them; building a concrete retaining wall, 700 ft. up both sides of a creek; re-arranging the sewerage system of the yards; building a $35,000 reading room for employees on an artificial fill of earth with rock shoulder.

The first work to be started, now nearly completed, was building a dike or embankment along the river. The new main tracks are to be built on this embankment,

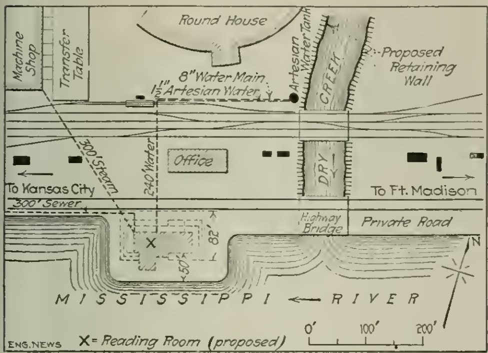


FIG. 1. GENERAL LAYOUT OF MAIN PORTION OF WORK

the present main tracks to be used for switching purposes in yard limits.

Grading for Change of Main Lines

rading for the embankment began on Oct. 23, 1913, and when completed on June 27, 1914, 150,000 cu.yd. had been placed on the south side of the present line, for a distance of 1½ mi. The subgrade is at El. 530.20; base of rail will be 1½ ft. higher. The grading was done by the Mississippi River Power Co., which purchased the land from which to obtain the fill and installed a steam shovel. Earth was moved by a train of 10 cars of 12-cu.yd. capacity each, drawn by a 40-ton locomotive. The average haul was 1 mi., and about 1500 cu.yd. were placed per day. The cost of grading, including the cost of the earth on the land purchased, transportation and placing, coal and engineering, was 28c. per cu.yd.

Riprapping River Bank

Rock for riprapping is hauled from a quarry at Dumas, 20 mi. west. This part of the work began on May 29, and on July 13 the bank was protected for more than a mile; a month later another mile of bank had been riprapped. Work is progressing eastward. The rock is dumped from cars; the average distance from rail to shoulder is 11 ft. Large pieces are used and the interstices are filled with smaller pieces placed by hand.

In the first part of the riprapping, only 1 cu.yd. of rock per lin.ft. was required; but opposite Fort Madison as much as 7 cu.yd. was used, the water being 20 ft. deep. About 30,000 cu.yd. of rock were used to protect the bank to the Mississippi River bridge of the Santa Fé, a total distance of 3½ mi. The cost of riprapping averaged $1 per lin.ft. of bank. L. W. Lewis Sons, Emporia, Kan., was the contractor for the A., T. & S. F. Ry. Co.

Raising the Buildings

All buildings, yards and tracks will be raised 3 ft. The general plan is to raise the doors and windows and to raise the floor by filling. In the machine shop the machinery will be raised, concrete foundations placed under them, and sand filled in around. Some of the smaller buildings can be jacked up. The roundhouse and the apprentice building, built in 1912 and 1913 respectively, are above high water. In addition to the yard buildings, there are 20 boathouses along the river front, which will have to be jacked from 4 to 6 ft. and stone foundations put under them.

It is estimated that the raising of the yards and tracks will require 700,000 cu.yd. of earth. This part of the work has not yet been started, but will probably be done by the railway.

Handling Sewage and Ground Water

The whole work necessitated the rearrangement of the sewerage system. All sewers having outlet to the lake had to be raised, as the flow line was at El. 525. To temporarily handle the sewage from the shops, two 6-in. electric-driven centrifugal pumps were installed and a 6-in. steam-driven emergency pump. These pumps were

FIG. 2. DUMPING RIPRAP ON EMBANKMENT

placed in a catch basin; one pump operates continuously, the other only when there is a surplus of water in the basin.

The pumping plant in the borrow-pit comprises a 6-in. and a 10-in. electric-driven unit and 10-, 12-, and 18-in.

FIG. 3. RIPRAPPED EARTH EMBANKMENT, SANTA FÉ RY., SHOPTON, IOWA

steam-driven pumps. This plant handles the drainage from an area of about 600 acres, and the sewage from the Prairie Oil & Gas Co. and from a packing-house plant nearby. A dike was constructed around a portion of this area to keep out the backwater. These pumps work automatically, and two men are sufficient to attend to them—one in the day and one at night.

W. H. Bush, who has charge of the whole work, sums up the unfinished items thus:

"The buildings and tracks have not yet been raised; the retaining wall up Dry Creek has not yet been built; the reading room is scheduled for erection this fall; the

main tracks will probably not be changed over on the new embankment until next year. The Mississippi River Power Co. can raise the water to El. 525, but it is doubtful whether this will be done for some time, as there seems to be sufficient water at the present time for the development of 150,000 hp. For the past year the river has been at El. 521.

A Home-Made Mowing Machine for Railway Track

The mowing of grass and weeds along the track is slow and tedious work for the section gangs. The accompanying cut shows a weed-cutting machine rigged up by Gordon Briggs, section foreman on the Chicago Great Western Ry., at McIntire, Iowa.

The blades and operating mechanism of a farm mower were attached to a push car, on which was mounted a 2½-

Home-Made Weed-Cutting Machine on the Chicago Great Western Ry.

hp. gasoline engine to propel the car and run the mower. The machine can be run at about 4 m.p.h., and has made 20 mi. with 1 gal. of gasoline. It will cut a strip 6 or 8 ft. wide, and is said to do the work better than hand mowing with scythes. The machine was described by J. T. Evans, formerly Engineer of Maintenance of Way, in "The Maize," published at Chicago by the railway company, to whom we are indebted for the photograph.

NOTES

Working Drawings on Limp Linen are used for all field work on the new [illegible] [illegible]

Developing an Inland Gravel Pit by a Hydraulic Suction Dredge [illegible]

opened up a large gravel pit for ballast, using a steam shovel. Later, a gravel company took over the development of the deposit, erected a hydraulic suction dredge in the pit and dug a ditch from a nearby stream to float and operate the dredge. The gravel bank then stood about 18 ft. above and extended 28 ft. below the water. The gravel overlies strata of blue mud and is about 65% sand, while 92% is fine enough to pass a 1-in. ring. The dredging outfit consists of a [illegible]-ft. hull, an old locomotive boiler, a Morris Machine Co. direct-connected centrifugal pump with about 10-in. suction and 10-in. discharge, three American Hoist & Derrick Co. single-drum reversible hoisting engines for swinging and raising the cutter head, a 4-in. piston pump for priming the centrifugal pump, and a boiler feed-water pump. Pine wood is used for fuel. The crew consists of a chief engineer and two assistants, a fireman and a wood gatherer. The discharge pipe line extends about [illegible] ft. away from the dredge and rises to an elevation of about 40 ft. above the dredge. The discharge is made into a steel pan, which widens out in a length of 10 ft. to a width of [illegible] ft., spreading the sand and gravel on a bar screen [illegible] bars on edge), with 1½-in. openings to remove roots, stones, etc. The material then falls on a series of sloping woven-wire screens and thence into sand or gravel bins from which railway cars are loaded by gravity. In addition to the dredge crew already noted, three men are required to load cars, four in the screen house, and a boy on top of the discharge pipe, whose duty it is to watch the discharge for clay and signal the dredge when the cutter gets into this material. The means of operation seem particularly efficient and cheap.

Semiportable Sand and Gravel Washing and Screening Plant —The plant shown in the accompanying view has a capacity of 110 to 1[illegible] cu.yd. of washed sand and gravel per day and makes a washed sand which is the undersize of a ¼-in. round hole in the "New Century" screen having a speed of 20 r.p.m., located on top of the bins. The washed gravel is the oversize of this ¼-in. hole and the undersize of a grizzly or bar screen having 2-in. spaces between the bars. This screen is located between the head of the elevator and the feed hopper of the sand screen. The oversize from the bar screen passes off to the spoil, as indicated in the illustration.

The washed sand is elevated by the [illegible] into a chamber on one side of the tank in which the sand screen revolves. It then passes to a sand box located between the

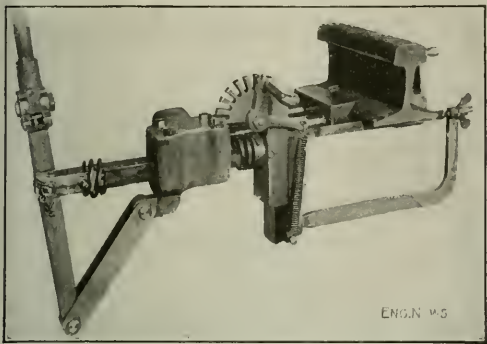
Semiportable Sand and Gravel Washing and Screening Plant

[illegible]

A traction engine is used to drive the plant. The original plans called for a motor of 25 hp. The plant described was built by the American Concentrator Co., Springfield, Ohio.

A Portable Rail Saw for Track Work—The special feature of the rail saw shown in the accompanying cut is that it can be used on rails in the track without interfering with traffic, since it makes its cut upward from the base of the rail. It is of the hacksaw type, with a double-acting saw which is given a reciprocating motion by means of the lever at the left. It is intended for steam, electric and street railway work (cutting track rails and third-rail conductors), and can be adapted for cutting structural steel.

The frame lies between the ties, and is clamped to the base of the rail, the clamp being drawn tight by the small



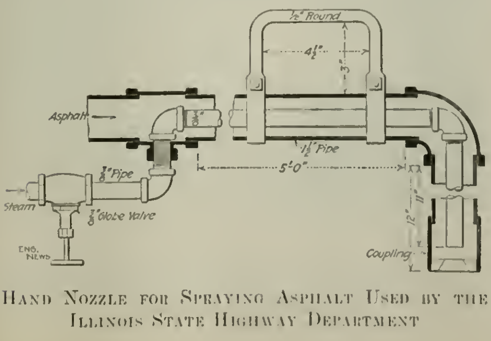
A PORTABLE HACKSAW FOR CUTTING RAILS

lever shown at the right of the rail head. At each vertical inch of cut, the saw frame is automatically shifted upward in the end frame, this being effected by the toothed sector. The machine is entirely clear of trains, except when the saw reaches the height of the wheel flanges. Should a train pass at that time, the wheels would simply snap the saw blade. The operating lever is removable, and its socket is pivoted so that if the level should be struck by a car or train it would be simply thrown over parallel with the rail.

The double-acting saw blade used in the machine is of a special (patented) design. Each saw is coated with a special lubricating composition which is softened by the heat developed in cutting the rail, and which is of such a character as not to affect the temper of the steel.

The machine weighs about 100 lb. in the size for cutting rails up to 6 in. deep or 125 lb. for 9-in. rails. The machine, the double-acting saw blade and the lubricating composition are all inventions of Alex Reitlinger, New York, N. Y. The Western agent is J. M. Scheer, 708 Tacoma Building, Chicago.

A Hand Nozzle for Spraying Heavy Asphalts—The accompanying illustration shows the details of a spraying nozzle used on all the asphalt distributing wagons of the Illinois State Highway Department. Steam and compressed air are supplied by a steam road roller or traction engine, used to draw the asphalt tank wagon. The nozzle is attached to the tank wagon by a flexible hose connection and the hot liquid asphalt is forced out under air pressure in the usual way. This type of nozzle is suitable for all grades of asphalts or

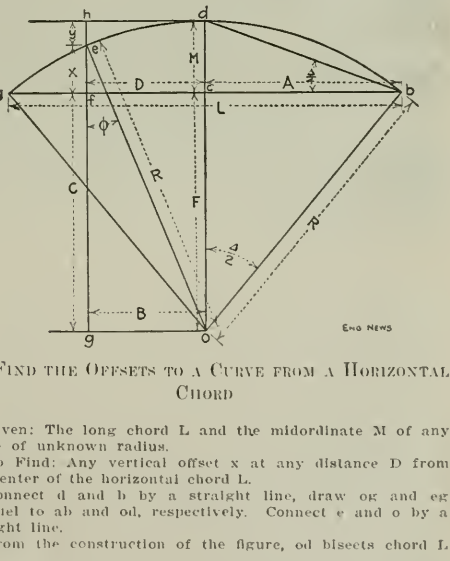


HAND NOZZLE FOR SPRAYING ASPHALT USED BY THE ILLINOIS STATE HIGHWAY DEPARTMENT

tars. It has been found to be very satisfactory in surface-oiling roads, as the material can be applied in a very fine mist in any quantity desired from ⅛ gal. to 2 gal. per sq.yd. The steam connection near the base of the spray superheats the bituminous material and also breaks it up into a very fine spray as it comes from the nozzle under the air pressure. There are other advantages in this type of nozzle, inasmuch as the high pressure that can be secured will remove surplus dust from the surface of the road and also force the bituminous material into all interstices of the road surface.—[P. C. McArdle, Acting Chief Engineer, Illinois State Highway Department.]

For Sanding Slippery Asphalt Pavements and for sanding bleeding wood-block pavements a machine has been recently put on the market by the Kindling Machinery Co., Milwaukee, Wis. The device consists of an ordinary wagon, hopper-bottomed, the hopper feeding into a fan or spiral bladed sheet-steel disk, which revolves in a horizontal plane a few inches above the pavement. The disk is turned by bevel gears, the driving gear being mounted on a countershaft, which in turn is driven by a chain from the axle of the wagon. The sand is thrown, varying with the speed, a distance of from 20 to 60 ft. A lever operated by the driver controls the feed of the sand. The apparatus is claimed to spread 50,000 sq.yd. per hr. The material may vary from fine sand to 1¼-in. stone, so that the apparatus may be used in road-construction work.

To Find the Offsets to a Curve from the Long Chord—The following may not be an original solution, but I do not recall seeing anything exactly like it, and I find the method I have worked out gives accurate results and is easily handled. Besides giving the tangential offset to a curve at any point whatever, the radius and central angle for any simple curve may be obtained, the midordinate and long chord being given.



TO FIND THE OFFSETS TO A CURVE FROM A HORIZONTAL CHORD

Given: The long chord L and the midordinate M of any circle of unknown radius.

To Find: Any vertical offset x at any distance D from the center of the horizontal chord L.

Connect d and b by a straight line, draw og and eg parallel to ab and od, respectively. Connect e and o by a straight line.

From the construction of the figure, od bisects chord L at c.

Call central angle of curve Δ, then angle dbc $= \frac{\Delta}{4}$, then $\tan\frac{\Delta}{4} = \frac{M}{A}$ and Δ is known. The radius, $R = \frac{A}{\sin\frac{\Delta}{2}}$ and $F = R - M$.

Solution 1	Solution 2
In triangle oeg	In triangle oeg
$(x + C)^2 = R^2 - B^2$	Solve for angle ϕ $\left(\sin\phi = \frac{B}{R}\right)$
then $x = \sqrt{R^2 - B^2} - C$	then $\cos\phi = \frac{(x + C)}{R}$
But B = D and C = F.	$\therefore x = R\cos\phi - C$
Substituting we have	C = F, and substituting we have
$x = \sqrt{R^2 - D^2} - F$	$x = R\cos\phi - F$

The tangential offset $y = M - x$.

It will be found that solution 2 is the better, particularly if R and F contain more than four figures, as solution 1 then

[illegible] It will be found necessary to carry [illegible] F [illegible] four [illegible] for accurate results.—[illegible], Engineer, Department of Public Works, Fort Wayne, Ind.]

Care in Handling Paving Brick, to reduce breakage, was [illegible] by a contractor [illegible] at Philadelphia. In [illegible] the bricks from [illegible] to wagons, [illegible] was employed and chutes were used to slide the bricks instead of throwing them by hand. In unloading at the street a gang of eight men was employed, two or three in the wagon passing the bricks to the others, who stacked them in piles. The men wore leather guards on their hands. Other contractors on the same work had the drivers and helpers throw the bricks from the cars into the wagons; at the street, the bricks were dumped and boys were hired to stack them.

A Detachable Stone and Gravel Spreader for use on an ordinary dump-wagon is illustrated herewith. This attachment (Fig. 1) consists of an outwardly flaring extension bolted to the rear of the wagon body. To this extension is hinged a series of chutes of telescopic design to permit of adjustment for spreading different depths of material. The free end of each chute rests upon a rail or track which projects to the rear between the chutes, so that the mouth of the chute is

Road-Oiling Truck with Interior Pump—Road-oiling apparatus often causes waste of time and oil, due to the necessity of cleaning the pump out with distillate to remove gummed oil of the previous day's work, and running out a barrel or so of oil at the side of the road before starting work to get the nozzles open and hot. In a new truck used in Pasadena, Calif., these faults have been eliminated by mounting the rotary oil-driving pump inside the tank, where the heat of the oil warms up the pump, and by using a nozzle header that permits a preliminary circulation of hot oil.—[Frank Reed, Los Angeles, Calif.]

A Remarkable Cotton Duck Belt recently made by the Gandy Belting Co., Baltimore, is 712 ft. long, 36 in. wide. The belt weighs 6[illegible]0 lb. This belt is of the type invented by Maurice Gandy 36 years ago. It is made of heavy-weight cotton duck of special weave, stitched with a heavy sewing cord on machines which make an embedded stitch producing a smooth surface. The stitching is done while the belt is under tension. Both edges of the belt have selvages. After sewing the belt is treated by a special oil process which renders it waterproof and keeps it pliable. Belts of this type have made records of [illegible] years' service as sand conveyors, carrying hot sand at temperatures of [illegible] to [illegible]°.

Editorials

The Boston Society of Civil Engineers, like the Cleveland Engineers' Club, has recognized its duty to the public and its members by arranging to give out to the daily press readable accounts of such of its activities as are of general interest. Already the Boston newspapers, like those of Cleveland, have shown their appreciation of this action by devoting liberal space to the "copy" supplied them. Doubtless other local engineering societies will follow the lead of Cleveland and Boston. Why should not the national societies do for the daily press of the whole country what the local societies are doing so well for the press of their own cities?

Rails and Rail Failures in Relation to Train Accidents

It is a matter of deep regret that the unsatisfactory quality of our American rails should be so general—a condition which has so often been made apparent. In fact, our rails, railways and rail mills are commonly criticized abroad on account of the amazing character of some of the steel rails furnished to and accepted by American railways. This condition has been contributed to by the policy of the railways in accepting the rails as made to the makers' ideas and specifications and ignoring the protests and specifications of the railway engineers. Some particulars as to experiences and conditions on individual roads are given elsewhere in this issue.

The railway engineers know what rails should be and how they should act. The position taken by the steel companies has been that they as manufacturers were the best judges of what grade of steel should be used and how rails should be made. This may be so in theory, but it does not work out in practice, and their position is not supported by the character of their product. Doubtless one reason for this is that the operations of the mills are controlled by commercial and not by scientific considerations. Prices also are regulated arbitrarily and have little relation to cost or quality of product. The difficulty in getting manufacturers to deliver good rails has been accentuated by the fact that the railway engineers have not always had the full support of the executive officers of their own roads, there having been a tendency to accept statements of the rail makers' representatives at the latter's own value.

This controversy between the railway engineers and the rail makers is of some years' standing. The engineers' side of the case has been most forcibly presented by the Rail Committee of the American Railway Engineering Association, which for some years past has been compiling very complete statistics of rail failures and has made careful examinations of rails, with results far from complimentary to American rail manufacturers. This committee has sought not only to draft specifications which will result in good rails, but has sought also to secure the adoption and enforcement of these specifications. It must not be thought that the Association has assumed an arbitrary position. On the contrary, it has sought strenuously to secure the harmonious coöperation of the steel interests, its sole object being to secure good rails in the interests of the railways and traveling public.

Taking a position of superior knowledge, however, the rail makers have presented steady opposition to the improvements suggested, requirements made, and specifications prepared by railway or independent engineers. In support of their stand they have argued that the main cause of the numerous breakages in modern rails lies in the heavy wheel-loads and high speeds characteristic of modern main-line service. This argument, however, fails to account for the fact that so many rails on investigation show a defective quality of steel and defective methods of manufacture.

It must be said also that by no means all (or even a large proportion) of the rail breakages occur under the most severe condition of service. It seems evident that the lack of strength of the heavier rail is due not to its size or weight but to the defects of its steel. In fact, it has been rather general experience that defects occur in such heavy modern rails which are not found in older rails of lighter weight, even when both carry the same engines and traffic. On this point the 1914 report of the Rail Committee makes the following deductions:

(1) The average performance of the heavy sections (85 to 100 lb.) is not so good as that of the lighter sections (72 to 80 lb.).

(2) The wide variation in results must be due to a large extent to a lack of uniformity in the performance of different mills and in the product of any individual mill.

(3) The majority of failures are head failures (such as split or crushed heads) and are due not to imperfect track conditions, but to defective material in the rail.

Appended to this report is a review of the rail-failure statistics, by Robert Trimble, Chief Engineer of Maintenance of Way of the Pennsylvania Lines (Northwest System). Mr. Trimble's review contains the following statements:

It is evident that the section of the rail as a rule has little influence on the quality of the material. A study of the detail reports makes it clear that other factors in the section are responsible for the difference in performance of different lots of rails. Small differences in chemical composition are not of much importance. Density of traffic, speed and wheel loads are of importance principally as they determine the weight of rail. Probably the majority of rail failures are due to faulty material; that is, segregation, slag inclusion, pipes, etc.

An important indication of the report is the great variation in the rate of rail failures for rails of the same weights and sections under practically uniform conditions of service. On one road, the same section of rail made by two different mills showed 81.5 failures per 10,000 tons for one mill and 124 for the other; in a similar case, the failures were 32.9 and 2.5 for two mills. In a third case, rails of similar section made by three mills showed 35, 186 and 617 failures per 10,000 tons. Mr. Trimble points out that these variations point to the same conclusion that was reached in 1913, namely: "Variations in performance of rails must be attributed to variations in the performance of different mills and also to

variations in the performance of the same mill at different times.

In conclusion, we may state two definite points. In the first place, a small number of accidents caused by broken rails is no evidence of good quality of rails, but is due largely to watchfulness induced by general suspicion of the quality of rails (which suspicion is the result of wide experience). In the second place, a steady improvement in quality of rails is being made, mainly through the united and continued efforts of railway engineers, with some assistance from the steel companies, but in general against the opposition (passive and active) of the companies. Naturally this will result eventually in a reduction of broken rails and accidents due to this cause.

Finally it may be pointed out that while rails of good quality are highly necessary, they are not likely to be obtained under the careless method of simply placing an order and letting the manufacturers decide as to the quality of the material furnished.

The Steam-Boiler Law Proposed by the Mechanical Engineers' Committee

Doubtless the most important subject ever brought before the American Society of Mechanical Engineers is the proposed code for the construction and installation of steam boilers which was laid before the annual meeting in New York City last week. We have referred before to the important work which the committee of the Society is doing in drafting this code.

It would be difficult to find anywhere a precedent for such important work being undertaken by a committee of a technical society purely out of public spirit and without recompense for the time and money spent.

Members of the committee deserve the highest credit for the industry and self-sacrifice they have exhibited in their work on this important matter in the three years since they were appointed, and particularly during the last few months since their work has been under active discussion and criticism by the various interests affected.

Whatever criticism may be made of the committee's work, there can be none of the spirit with which it has pursued its work and with its commendable aim to protect the public safety and bring order out of the present chaos produced by conflicting state legislation on steam-boiler construction.

We believe this situation was generally realized by the members present at the meeting of the Mechanical Engineers last week, and that it was because of respect for the members of the committee and their excellent motives that the committee's report did not receive even more severe criticism.

What happened, briefly stated, was this: The committee presented at the opening business session of the meeting last week the preliminary draft of its progress report, including its rules for the construction and installation of steam boilers, omitting, however, certain tables, tables and forms which have appeared in previous reports and which, it is understood, are to be included in the final report of the committee when completed.

This preliminary draft of a partial report, however, made a book a quarter of an inch thick, and it is this which the committee, after amendment, proposes to have recommended to the various state legislatures for enactment into laws to govern the construction and installation of steam boilers.

The committee brought this preliminary draft to the meeting to have it taken up, section by section, and discussed in detail; and this plan was actually carried out, the committee and those particularly interested in the subject meeting day after day, morning, afternoon and evening throughout the whole time of the convention.

It would be difficult to overestimate the value of this discussion, which was participated in by the ablest experts in steam-boiler design in the United States. There is no doubt that the rules which the committee has drafted will be greatly improved as the result of the discussion last week.

A more important matter than details, however, claims attention and received some discussion in the general business meeting of the Society on Wednesday forenoon. This more important matter is the question whether the committee is proceeding on the right course in preparing this voluminous code for enactment into law. So far as it was possible to gage the general sentiment of the members assembled in the Society's business meeting on Wednesday last, we judge the majority of the members would oppose this. In fact, a motion was made which would have had the effect of putting a sudden end to the committee's work; and though the motion was voted down, it received considerable support.

It seems to us that the committee has been led into error, partly through its zealous desire to accomplish a monumental piece of work and partly through the idea that further state legislation on steam boilers must necessarily follow closely such laws as that of Massachusetts, already in force. Actuated by these ideas, the committee has framed a code which comes near being a detailed scientific treatise on the best engineering practice in the design of steam boilers. Valuable and important though such a treatise may be to the engineering profession, it is most unwise to offer such a treatise for enactment as law by a state legislature. Experience has shown, when legislation on technical matters has been enacted, that it has been well nigh impossible to secure its appeal or amendment when the progress of the art renders obsolete matter which was commendable enough at the time it was embodied in law.

If the Mechanical Engineers' Boiler Code Committee desires to secure useful results from the work it has done, it should at once proceed to divide its voluminous report into two parts. The first part, and admittedly the most important, should cover as briefly as possible only those general features of boiler construction, installation and inspection which might reasonably be embodied in law and issued as a guide to boiler inspectors employed by the state or by insurance companies. Nothing of a controversial nature should be included in this portion of the report and nothing which is likely, so far as can be seen, to be subject to material alteration by the progress of the art in the next twenty years at least.

All the rest of the committee's report should be issued after revision as a committee report of the Society, and would have the same standing for the guidance of engineers engaged in the design, construction and operation of steam boilers as has the Society's standard code for steam-boiler tests so long in use.

If the Boiler Code Committee will proceed along these lines, we believe all opposition to its proposed code will disappear, and all interests will unite heartily in furthering its acceptance by the Society, and its embodiment in state legislation.

If, however, the contrary course is followed and the committee offers its entire voluminous report for approval by the Society's Council, by the Society itself and finally for enactment by state legislatures into law, we believe the code will fail of adoption.

Experience has shown that it is a huge mistake to encumber our statute books with all sorts of detailed, minute provisions for the regulation of every industry and business. The damage and injury which the public suffers from such legislation far outweigh any benefits realized. The American Society of Mechanical Engineers has a great responsibility in this matter, as we have before pointed out. Numerous states desire to pass legislation governing the construction of steam boilers and would welcome the intelligent aid of the leading technical society in this field. For this very reason it is of extreme importance that the Society's leadership shall be a wise leadership. The Society has the opportunity to frame legislation which will be conservative, simple and practicable of enforcement, leaving all the multitude of details, involving intricate matters of detail practice, to the members of the engineering profession who are properly responsible for such work. We repeat that no more important matter has ever been presented to the American Society of Mechanical Engineers.

Letters to the Editor

Financing Public Improvements on the Pay-as-You-Go Plan

Sir—I note in your issue of Nov. 26, 1914, a communication from E. P. Goodrich, Consulting Engineer to the Borough of Manhattan, expounding the financial merits of the pay-as-you-go plan as compared with the bond-issue plan for public improvements. The conclusion at which Mr. Goodrich arrives as to the economy of the pay-as-you-go plan has been set before us by various financial experts and efficiency engineers for some time without calling for a great deal of notice. But when an engineer of Mr. Goodrich's standing brings forward the same claims, it moves me to voice a protest against this method of practically lifting ourselves by our bootstraps.

As an example of arithmetic, Mr. Goodrich's arguments are unexceptional. They rest, however, upon an entirely false assumption. The assumption is tacitly made, without any particular attention being called to it, that an improvement year is always of the same value to the community, no matter at what time such improvement year may be enjoyed. The total number of improvement years obtained from the bond-issue plan is compared with the total number of improvement years obtained from the pay-as-you-go plan, and it is of course found that there is a difference arising from interest paid on the bond issue.

The essential falsity of this assumption lies in the fact that an improvement year today is worth more than an improvement year in the future, and that improvement years are not to be taken together in simple summation, but improvement years must be weighted in accordance with the time of their first being enjoyed, much the same as money values are weighted, and money today is worth more than money 25 years from now and the relative value can be obtained by compounding money today or discounting money values 25 years from now to present worth.

Because many if not most of the improvements obtained by the expenditure of public moneys do not return a direct financial profit, this fact is often lost sight of. If, however, a million dollars be spent in erecting, say a municipal office building, and the annual expenses of this office building and interest, etc., amount to, say $100,000, and the office building saved $200,000 in rent money, there is an evident profit in having the office building erected today rather than 10 years from now, and it is easy to see without further argument that the improvement year at the present time is worth more than the improvement year 10 years from now. For such improvements as street paving, no direct financial comparison can be made. It is fair to assume, however, that the improvements would not be made if they did not bring some return, sentimental if not financial, to the public. It is also fair to assume that the return obtained from such improvement is proportionate to the cost. For instance, if the paving in a street is improved today, it may save the public in hauling charges some definite return on the investment which may amount to as much as, or to a considerable amount more than, the fixed charges. This saving to the public is in itself available for further returns to them, and the total gain at the end of 50 years or so must be the compounded value of these various savings.

Speaking in general terms, and no mathematical determination is possible, the value of improvement years increases from the future to the present, and an improvement year is properly to be taken as more valuable at the present than in the future. The value of an improvement year today, taken at the end of 50 years, is to be the compounded value, the rate of compounding depending upon the value of the improvement to the community. On the other hand, the value today of an improvement year at the end of the 50 years is the reduced or present worth of such an improvement taken at this same rate of interest. An improvement year, 50 years from now, of $1,000,000, if improvements are worth only 5% to the community, is today worth only $87,000. What this rate of interest should be depends upon the nature of the im-

provement and its value to the community, and may well be as much as the rate of interest on bond issues, or even very much more than this rate of interest. Whether the total benefit of the improvement to the taxpayers is greater or less by the bond-issue method or by the pay-as-you-go method depends more upon how the money is spent than upon the method of raising the money. If the money be spent for worth-while improvements it is economical to make them today by bond issue. If, on the other hand, the money is spent for extravagant and wasteful improvements, it is better to use the pay-as-you-go method.

This conclusion may be properly reached quite independently of the question of how much money may be worth to the individual taxpayer. If it should be true that money is worth more to the individual taxpayer than the cost to the community as shown by the amount of interest on the bonds, the value of the bond-issue method may be still greater than indicated by the above.

CHARLES B. BUERGER.

Current Meters for Measuring Flow in Pipes

Sir—On account of the discussion in ENGINEERING NEWS, Sept. 3, 1914, p. 510, on the use of current meters for measuring the flow of water in pipes, and in connection with the previous articles there referred to, it may be of interest to mention an earlier instance of a somewhat similar application of a current meter.

I refer to the adaptation of the Haskell current meter to the measurement of flow from artesian wells in Memphis, Tenn., as early as 1890 or 1891. I think the details of the apparatus were the work of E. L. Cooley, then Chief Engineer of the Memphis Artesian Water Co., and that the idea originated with him or with the late Dana T. Johnston. Mr. Johnston also had an improved current meter constructed for use in the Savannah, Ga., artesian wells in 1897 (and described in the Journal of the Western Society of Engineers, 1897, p. 711).

The writer used the Haskell meter for metering some forty wells in Memphis once each month during most of the year 1892. The meter was attached to the end of a line of pipe and lowered down the well to a point a few feet below a tunnel connection, which was a special T-casting through which the well discharged into the tunnel system there, conducting the water to a wet well under the pump house. The meter was held centered in the well by means of a framework or basket slightly smaller in diameter than was the inside of the well casing.

The revolutions were ticked off on a counter connected in circuit with the current meter and dry batteries. The rating of the meter was made in a pipe discharging water out through the same kind of a T-casting as used at the tunnel connections, the water passing over a weir for measurement.

H. P. BOARDMAN,
Department of Civil Engineering,
University of Nevada.

Reno, Nev., Nov. 14, 1914.

NOTES AND QUERIES

The three-wheel electric tractor for drawing a street sweeper, illustrated on page 1111 of "Engineering News," Dec. 3, is made by the Clarence L. Smith Co., New York City, instead of the Wirt & Knox Manufacturing Co., of Philadelphia, as stated in the caption under the illustration. The Wirt & Knox Manufacturing Co. is a manufacturer of street-cleaning apparatus only and not of tractors and motor trucks.

William E. Per Lee, of Stillwater, Minn., is desirous of learning the present address of his brother, H. B. Per Lee, who was last heard from at New Orleans, La., June 8, when he was registered at the St. Charles Hotel. He is a civil engineer and his last known place of employment was at Elephant Butte, N. M. Any reader knowing his present address will confer a great favor by communicating it to his mother, who is ill, and his brother.

Pavement Problems and Experience in San Francisco

By JAMES M. OWENS*

San Francisco may well be called a City of Hills, for almost in its geographical center are located the "Twin Peaks," approximately 925 ft. above sea level, while just to the southwest of them is Mt. Davidson, some 13 ft. higher, and in addition there are a great many minor hills and ridges. It can readily be seen, therefore, that San Francisco presents to the highway engineer many and serious problems.

GRADE PROBLEMS—Some of the grade problems may be better understood by citing a few examples:

In the heart of the business section there is a block with a gradient of 29.8%, paved with cobbles. In one of the most thickly populated residence districts, along one of the main trunk lines leading to the Panama-Pacific Exposition Grounds, we have a double-track electric railway line operated with cable traction helper over a gradient of 26.5%. This street is also paved with cobbles.

In an outlying district a vitrified brick pavement on a concrete base has recently been constructed on a street whose gradient is 18.1%. This pavement (Fig. 1) is unique in that the brick selected are not of the "hillside" type but of a special, rough, irregular kiln-marked variety. I do not know of another instance where paving brick of this kind has been laid on a city street having such a heavy gradient.

Not far from the Exposition Grounds on Chestnut St., east of Polk St., a block has just been graded, for half of which the gradient is 33.3%.

In the vicinity of the waterfront there is a considerable area of filled-in land, where there is a regular yearly subsidence of about 0.1 ft. Taking care of this settlement and harmonizing the grades in that locality is one of the city's most difficult pavement problems.

ASPHALT PAVEMENT—One of the largest and best known bituminous limestone deposits in the United States is located not more than 120 miles from San Francisco, and this was developed in the early eighties, and as California is now the largest producer in the Union of crude oil and asphalt, it is not to be wondered at that the majority of this city's paved streets are of these materials.

In the past few years, under the supervision of the

*Assistant City Engineer in Charge of Pavement Dept., City Hall, San Francisco, Calif.

city engineer, there have been laid in this city about 798,542 sq.yd. of bituminous limestone rock as against 590,617 sq.yd. of other types of asphalt during the same period.

The bituminous rock, as it is found in California, is graded commercially as hard, medium and soft. The nature of these deposits was described and a chemical analysis of the rock given in an article by me in Engineering News, Dec. 22, 1898.

Fig. 1. Residence Street on a Steep Grade Paved with Special Brick

While the majority of our streets have been paved with this material as it came from the mines, without any attempt being made to grade it, of late years far better results have been obtained by proper grading and mixing. The old-fashioned and highly injurious closed steam kettle has been eliminated and the hot-air process substituted in its place.

Probably due to lack of knowledge concerning the nature of the material, a great many of the older pavements have disintegrated and in many cases present a very irregular surface, due to the tendency of the material to creep and form into waves.

Most of the material flowed toward the gutters, because of its excess of oil, its lack of proper bond with the foundation, and the stress of traffic. In some instances the original 2½-in. surface has thinned out to 1 in. at the center and increased to 4 in. at the gutter line. Probably most of this trouble is the result of excessive crowning, which in some of the older pavements was as high as 10%.

On most of the new asphalt pavements a radical departure from the prevailing height of crown was made, the crown being designed quite flat. This has aided in eliminating the tendency of the surface to wave. The entire absence of waves is particularly noticeable in the case of the Geary St. pavement, where some very flat crowns were used.

The paving of the Junipero Serra Boulevard, for its entire length from Ocean Ave. to the county line, is the most important paving work undertaken by the city during the past year. This stretch of roadway is about 1.6 miles long, and is the main route for motor travel from the city to the Peninsula. This work has been done by the City Street Improvement Co. at a cost of $53,340.

The paved portion of the roadway is 25 ft. in width, with 5-ft. rock shoulders on either side. The 3-in. thick concrete gutters are 5 ft. wide and 1 ft. 10 in. deep where they adjoin existing curbs. The pavement foundation is of cement concrete 6 in. thick. The concrete foundation has edgings 6 in. wide and 2½ in. deep so as to inclose the asphalt surface of 2½-in. thickness.

The asphalt surface consists of a 1½-in. close binder course and a 1-in. wearing surface. For the kind of traffic it will have to support this pavement is expected to give entire satisfaction for many years to come.

Other Pavements—New specifications are now being prepared to cover most of the best known of modern pavements, such as creosoted wood block, vitrified paving brick, asphalt, bituminous rock, bituminous concrete and basalt-block pavements.

On account of the excessive gradients on some of our city streets, cobblestone pavement (Fig. 2), if it can be dignified by the name of pavement, is still used, but probably will be replaced by a rough, irregular, kiln-marked brick, which will be far more sightly, practical and durable.

Vitrified-Brick Pavements—As previously mentioned, these bricks have been used on some of the outlying residence streets where the travel is light and infrequent on account of the grade and only recently on medium heavy traffic streets like 3rd St. and 6th St., where the standard hillside-variety was used. While not down long enough to provide a crucial test, these new brick give every indication that they will be satisfactory. Vitrified-brick pavement is still in its infancy here.

Outside of a few isolated, badly executed attempts made to introduce it formerly, the use of brick in this city practically began with the paving of Powell St. only

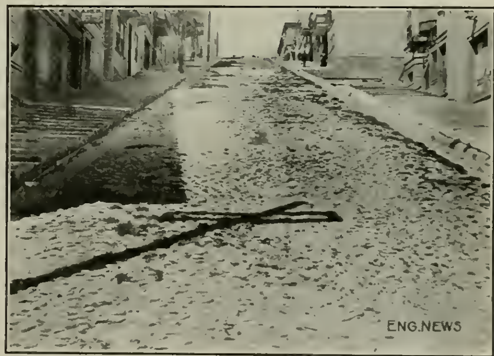

Fig. 2. Typical Cobblestone on Steep Grade Street

two years ago. Vitrified brick were laid on one side of the street and vitrified-paving block on the other. Today this pavement presents a remarkably even and good-looking surface and gives every indication that it will last.

Basalt-Block Pavements—Our basalt-block pavements, used for the heavy traffic streets, correspond to the new granite-block pavements of New York. In fact, the basalt block is a more durable stone and wears more evenly than the Eastern granite. The following is taken from the specifications for basalt blocks:

BASALT BLOCKS—The basalt blocks shall be of the best quality of basalt, not less than 3½ nor more than 4 in. wide; not less than 7 nor more than 9 in. long; not less than 6 nor more than 6½ in. deep. They must be so dressed as to have

[illegible] 3/4 in. and such that when two blocks are placed [illegible] end to end with the [illegible] the average [illegible] between [illegible] will not exceed [illegible] in.

When laid on a concrete foundation with a 2-in. sand cushion and cement grout or gravel filler, this is one of

Fig. 3. Portion of Junipero Serra Boulevard with 3-In. Asphalt Surface

the most durable types of pavement under heavy traffic. The chief objections to its use are its tendency to round off the edges and consequently become slippery and noisy.

Wood-Block Pavements—Outside of a small stretch of experimental pavement, laid under the jurisdiction of the Harbor Commission, on the Embarcadero, there are no wood-block pavements in San Francisco. Some will probably be introduced here in the immediate future, however.

Curbs—At the present time there are three kinds of curb in general use in this city, namely, California granite, armored concrete, and California redwood. Until recently, no concrete curb was specified by the city. It is gradually coming into use, however, and has recently been used to quite a large extent in the rapidly growing suburban districts, and particularly in tracts that have been opened up recently. Its cost is about midway between that of the redwood and the granite. Where sudden grade changes occur with such frequency as they do here, it is apparent that a curb that can be molded to any shape is more adaptable than the more rigid granite curb.

In spite of the heavy toll levied on the pavements of this city by the great fire of 1906, and the few years the city has had in which to recuperate from the catastrophe, street improvements have been carried on at a rapid rate. Much has been accomplished during the interval.

All pavement design and construction are under direction of M. M. O'Shaughnessy, City Engineer.

Pavement Problems; Contrasts of Foreign and American Practice*

By Henry Welles Durham†

A most difficult problem confronting the city highway engineer is to make a correct decision on a suitable form of pavement surface—one that shall, if possible, combine the very contradictory qualities asked for by the different interests involved.

The Requirements—Owners of horse-drawn trucks, who are still very influential, desire a surface that will furnish a good foothold for animals in addition to giving light resistance to traffic. The occupants of buildings desire noiselessness and cleanliness. The necessity for access to subsurface structures often requires the easy opening and restoration of the pavement to a condition substantially as good as the original surface.

Further, the taxpayer demands a form of construction that shall combine a minimum of original cost and subsequent maintenance with a maximum of durability; and the general critic calls for the discovery of some hitherto unknown perfect type, and refers us to the great cities of Europe, in which, as he knows from personal observation (during the few hours he spent in each and on the few blocks which he visited), the pavements are perfect, where repairs are never required, where openings are made during the night and restored before morning—all at practically no expense to the taxpayer.

Investigation does not bear out these claims, nor, unfortunately, does it discover the solution of the pavement problem. The municipal highway engineer [illegible] as in this country, is trying to satisfy the same [illegible] with the same limited [illegible]. The best to be said is that general experience has reduced to a [illegible] the number of desirable wearing surfaces for city streets, and the selection of the most suitable of these for each particular case is usually arrived at through a process of elimination, by taking the pavement that presents the fewest drawbacks.

American Practice—The [illegible] street pavement and that which is laid [illegible] half the area of

*[illegible] "[illegible] of [illegible] Construction and Maintenance of Roads and Streets" [illegible] American Road Congress, Atlanta, Ga., November, 1914.

†[illegible] Borough of Manhattan, New York City.

all city streets in Europe at the present time, is some kind of stone block, ranging in quality from the rough cobblestone pavement—which has been generally discarded in New York City, but is still very prevalent abroad—through various grades of squared block to one of hand-dressed blocks with joints of less than 1/4 in. and heads absolutely plane, found to a very limited extent in such cities as London, Liverpool and Birmingham and costing from \$5 to \$10 per sq.yd.

Citizens of none of our leading American cities would be contented to have in a residential street, macadam and stone block to the extent to which they prevail abroad. Consequently, lessons drawn from foreign practice are valueless to us in this respect; while we have already learned to construct stone and asphalt pavements of a quality equal to the best abroad.

The selection of the types of pavement to be adopted in a great city cannot be laid down to a set of rules whose observation will lead to the satisfaction of any community. Local climatic conditions, economically available sources of supply, the relation to each other of the different localities for commerce, manufacture and residence, and, finally, the financial resources of each city all exercise too great an influence to make the practice of one valuable as more than a general example for another.

Advantages of Modern Stone Block—As compared with other types of pavement, in view of its greater life and consequent ultimate economy, modern smooth-dressed, close-fitting, granite-block pavement on a concrete foundation, with joints filled with a bituminous material, has been decided to be most satisfactory for the heaviest traffic streets in the Borough of Manhattan, New York City. Its freedom from slipperiness and ease of maintaining in a clean condition, the small amount of repairs required, and the fact that it is the only surface in which street openings can be restored to a condition equal to the original surface, have been the determining factors, where the general city noises from surface and elevated railroads and other sources render variations in the type of pavement negligible so far as noisiness is concerned.

Advantages of Wood Block—For a fairly heavy and dense traffic in wide streets subject to infrequent cuts and having a level surface or only moderate grades, there is no question but wood pavements can be laid that are eminently satisfactory. They require the most careful attention for maintenance and perhaps vary in quality between greater extremes than any other type.

Nothing finer in the world in pavement surface exists than can be seen in London on the Mall from Admiralty Arch to Buckingham Palace, a street that is subject to a fairly dense pleasure traffic; or on Whitehall, the Strand, Piccadilly or many other adjacent streets in the heart of Westminster. On the other hand, some of the worst wood surfaces encountered in any city can be found within two or three miles of those just referred to, illustrating very clearly the absolute necessity of constant attention to maintenance and the selection of the best kind of wood and workmanship for this type of construction.

Advantages of Sheet Asphalt—For the combination of economy, cleanliness, absence from much noise, and satisfactoriness for the general city traffic in the residential districts, nothing better has been developed than the modern asphalt pavement. It has been adopted on a majority of the streets in New York City. While many miles of inferior pavement of this type have been laid there in the past, these are as rapidly as possible being replaced by a modern type of construction on a concrete foundation, which promises much greater durability and ease of maintenance.

The relatively lesser amount of this kind of surface in European cities is very largely due to the fact that American cities had no good pavements on any but a few streets up to very recently, whereas it has been the practice abroad for many years to construct good macadam surfaces in all residential districts.

At the present time, foreign cities are following our custom of laying sheet asphalt on new light-traffic streets, and in the large real-estate developments around Berlin asphalt was adopted almost exclusively. The cities of Paris and Vienna last year made contracts for extensive repaving with asphalt, which is being substituted in Vienna for the old stone surfacing of the Boulevard; while Paris is tearing out many miles of stone block, inferior wood and macadam and relaying with asphalt.

Need of Closer Supervision and Inspection—It would seem as if some of our city engineers thought that the whole aim of their office had been obtained when they had succeeded, down to the last period, in describing chemical and physical qualities of the materials to be used and the exact details to be followed; just as we Americans have too great a tendency to regard our record file and office systems as ultimate ends. The specifications used in such important cities as London, Birmingham, Liverpool, Hamburg and Berlin, and even Paris, where the most attention is given to detail of any city in Europe, seem noticeably weak in contrast to ours and to leave much to the honesty of the contractor. But when it comes to the execution of the work the attitudes are reversed, and the European engineer and contractor seem to work in harmony with but one end in view, namely, the construction of the particular piece of work called for at the price agreed upon.

A recognition of the difference of national traits furnishes no indication of how to change them, except in pointing out the direction in which almost all of our cities can obtain better work—that is, in the line of closer inspection of materials and workmanship of construction. It is a problem that is worthy of the attention of many men who may have a tendency to regard anything but the scientific end of engineering construction as beneath their dignity.

Conclusions—In concluding, the fact must be emphasized that the most satisfactory type of wearing surface is largely a local question. New York lays wood-block pavements only on level streets, Berlin only on grades. Other forms of block pavement than those largely used in New York City are giving satisfaction elsewhere. Many successful brick pavements and those of various types of bituminous concrete are laid in neighboring cities. The question of paving construction in and adjacent to the tracks of street railways is a problem by itself.

One point above all must be kept in mind—careful work for a short time will lay a good pavement; but it can be kept in its place in good condition for use only by constant vigilance. A thorough organization, for the purpose of inspecting and reporting defects and for the execution of immediate repairs, is the prime requisite of a good highway bureau.

The Palmer Memorial Stadium at Princeton University

SYNOPSIS—Details of design and construction of the largest reinforced-concrete stadium, seating normally 41,000 people. Simple design consisting of transverse inclined girders on columns and carrying continuous slab of seats.

Some weeks ago ENGINEERING NEWS devoted considerable space to the description of the so called Yale Bowl, the new amphitheater just completed at New Haven for the football contests of Yale University. Practically contemporaneously with the Yale Bowl there was completed at Princeton University, Princeton, N. J., a reinforced-concrete stadium for the same purpose, which, while somewhat smaller in capacity than the Yale structure, is the largest reinforced-concrete grandstand or stadium in existence.

The Yale Bowl is an elliptical amphitheater of earthwork, paved on the inside with reinforced-concrete seats, and having a normal seating capacity of 61,000, although at the Yale-Harvard game of Nov. 21, 1914, there were nearly 69,000 persons present, the extra 8000 being provided for by seats on the upper walkways. The Princeton stadium, on the other hand, is entirely of reinforced concrete. It is U-shaped, as is the Harvard stadium which was completed in 1903 (ENGINEERING NEWS, Apr. 27, 1905, p. 435), and it seats 41,000 persons as compared with 35,000 for the Harvard stadium, the next largest reinforced-concrete structure of this sort. Construction on it was going on all during the past summer and the field itself was used for two games this fall, the Princeton-Dartmouth game of Oct. 24 and the Princeton-Yale game of Nov. 14. At neither of these games were the seats completely filled.

The Princeton stadium was presented to Princeton University by Edgar Palmer, Class of 1903, in memory of his father, who was a graduate of Princeton College. It cost approximately $300,000. The architectural design was made by H. J. Hardenbergh, architect, New York City, the structural design by Purdy & Henderson, consulting engineers, New York City, and the contract was carried out completely by George A. Fuller Co., also of New York City.

Fig. 2 gives a half plan of the stadium, a section through it showing the structural design and a partial longitudinal section. From that drawing the general nature of the structure may be understood. It is horseshoe-shaped, the total length being 652 ft., and its total width 720 ft., both dimensions out to out of all concrete. The seats are in the usual bank, 72 ft. high at the highest point, and extend on tangents parallel to both sides of the playing field for a distance of 454 ft., at the closed end being connected by a variable-radius curve which brings the nearest seat at the crown of the curve as near as is artistically consistent to the goal posts located at that end of the field.

FIG. 1. THE PALMER MEMORIAL STADIUM AT PRINCETON UNIVERSITY, PRINCETON, N. J., AT THE YALE-PRINCETON GAME, NOV. 14, 1914

The entrance, at the outside crown of the curve, is made particularly pleasing from an architectural standpoint, as is shown in the view in Fig. 4. Through this entrance the playing teams enter the field. The stand itself is entered from 26 runways, which incline up from the outside ground level to entrances into the stands about halfway up their slope. The whole stadium is surrounded by a high iron picket fence to control ticket taking.

STRUCTURAL DESIGN

The structure is very simple. Reinforced-concrete columns, founded on simple spread footings, were spaced

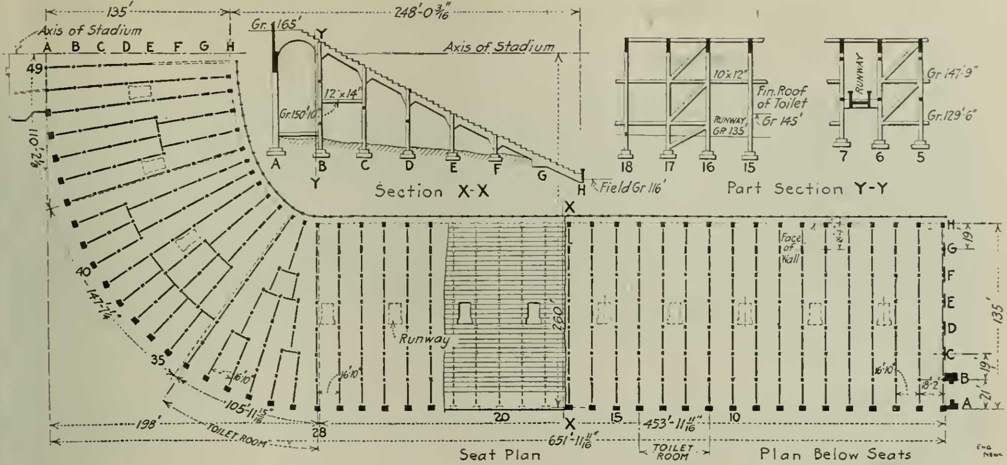

FIG. 2. HALF PLAN AND DETAILS OF REINFORCED-CONCRETE STADIUM AT PRINCETON UNIVERSITY

uniformly 16 ft. 10 in. longitudinally and 19 ft. transversely on the two straight sides of the stand and on approximately the same dimensions but on radial lines in the curved part. The transverse line of columns carries inclined girders which are notched on their top surface to the step shape. Spanning these girders, the steps themselves were cast as a continuous floor clear around the structure. There are no expansion joints, but special reinforcing was placed in the so called riser beams, that is, the steps, to take up any expansion and contraction.

The columns, except for the rear line, are 16x16 in. square, reinforced with straight rods tied together every 12 in. with ¼-in. wire. The two front lines of columns are so short as not to require regular column design, but are in effect mere pedestals. The columns in the rear line are each 4 ft. by 5 ft., and each has a recess on the inside face, as shown in the view in Fig. 5. Columns are braced by occasional horizontal beams in both directions and by longitudinal diagonals in the higher bents.

The girders are each 10 in. thick and vary in depth with the jogs in the steps. At the higher end the girders are formed into an arch which spans the 21-ft. opening, which is used for the promenade leading to the various runways. This arch carries on its forward half the last four

Fig. 1. The Entrance to the Princeton Stadium

steps of the stand and on its rear half a walkway used as a general concourse for walks before, during and after the game. This walk is protected on each side by a reinforced-concrete railing. The view in Fig. 5 shows the remarkably fine effect which this arcade presents to one passing beneath.

The line of the steps is not straight from top to bottom, but has a slight dip downward at the middle. This curve was worked out by experiments so as to permit each row of spectators to see the field to best advantage. In forming this curve the steps vary from 15 to 17 in. in rise and 2 ft. 5 in. to 2 ft. 7 in. in tread. They are reinforced by wire cloth continuous from bottom to top and by continuous longitudinal rods at each junction of riser and tread. The riser beams are further anchored to the girders by vertical rods 3 ft. long, penetrating both girder and riser. Up to the present the bare concrete steps have been used for seats but it is intended to put a 12-in. planed board seat along the front of each concrete step. The concrete steps, it will be noted, are wide enough to permit such a board to be used as a seat at the front end of the steps and to leave sufficient space at the rear end for a walk on each row.

Fig. 5. View Through Promenade Arcade at Rear of Princeton Stadium

The runways, spaced every third row of columns, are inclined slabs running up from a so-called concourse or walkway between columns A and B to the top of the stand at column E. They rest on transverse girders spanning between the columns and are protected by a solid reinforced-concrete railing. Inasmuch as the elevation of the concourse varies and the level of the runway openings at column E is constant, the slope of the runways varies from $1\frac{1}{8}$ in. to $2\frac{1}{4}$ in. per ft. At the first four runways from either end of the U, steps at the bottom were used in order to keep the slope within the above limits.

The foundation conditions at the site were good. Piles were not necessary. The columns have simple footings placed usually $3\frac{1}{2}$ ft. below ground surface, i.e., below frost depth. A few of them rest on shaly rock, while the others are on sand and gravel. A low soil pressure, 3 tons per sq.ft., was adopted in order to be safe in case variable material were encountered.

Construction

Work was started on the excavation for the Stadium Apr. 17, 1914; forms for the concrete work were started May 19, and the field was opened for its first game Oct. 24. The leveling of the field was the first operation. This was done by steam shovels and carts, 40,000 cu.yd. of earth being moved in this manner. After it was brought down to a level, a 30-in. playing field was made of successive layers of broken stone, cinders and turf, with open-joint drain pipes along the bottom. New turf was placed with considerable success. The playing field for the two games this year was quite up to expectations.

Concreting was carried on by two separate gangs, each a complete organization, beginning at the two open ends of the stand. These two gangs were worked one against the other and by the competition considerable progress was made. The concreting was done by chuting from towers which were about 160 ft. high. Each of these towers had to be moved once. In the beginning they were placed along the side and back of the stand, so that with the use of column-stopped troughs (Figs. 6 and 7), they could control about two-thirds of the straight side. When this had been concreted, they were moved up to near the

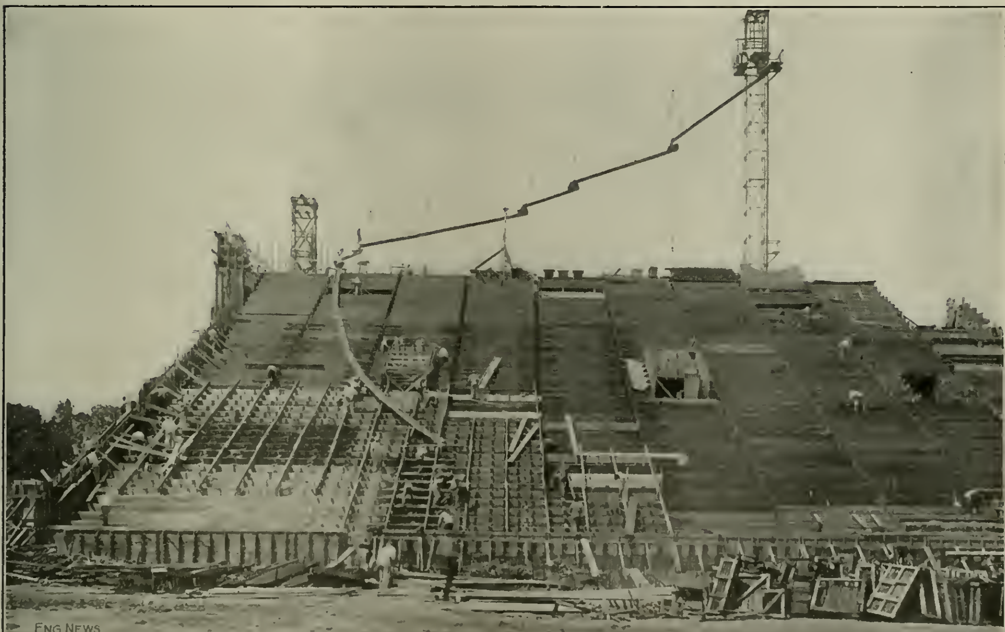

FIG. 7. LONG CHUTING OF CONCRETE FOR LOWER SECTION OF DECK, PRINCETON STADIUM

point of curvature and controlled the remaining part of the straight and half of the curved part of the stand. On account of the great length of trough and the irregularity of the line required a secondary tower was built solely to act as a guy-line tower to support the troughing. It can be seen in Fig. 7.

Mixers at the bottom of these towers were fed by barrows wheeled from the storage piles near-by. All machinery was electrically controlled. The greatest amount of concrete laid with one plant was 227 yd. in 10 hours.

Timber falsework was erected complete for three bays at a time. The falsework was cut at a sawmill on the job and carted to the proper location with horse and wagon. It consisted of straight posts thoroughly braced, carrying at the top the proper boxes for girder and risers. Two sets of three-bay forms were used on each side. Concreting was continuous, so that the first three bays could have been fully moved and in place for the next erection by the time the second three bays of concrete had been laid. Thus the forms were used four times.

Annual Meeting of the American Society of Mechanical Engineers

The 35th annual meeting of the American Society of Mechanical Engineers was held in New York City last week at the Engineering Societies' Building. The attendance was gratifyingly large, 821 members of the society and 512 guests being registered during the week.

At the opening session on Tuesday evening, Dec. 1, the retiring President, James Hartness, President of the Jones & Lamson Machine Co., of Springfield, Vt., gave an address entitled "The Human Element: The Key to Economic Problems." Mr. Hartness presented some of the ideas that were made prominent in his book, "The Human Factor in Works Management," with reference to the importance of recognizing habit as a most important factor in the development of an industrial organization and its personnel. Mr. Hartness also emphasized the idea that for economic production, business must be carried on upon a large scale and held that recent legislation in opposition to monopolies was contrary to the welfare of the nation as a whole.

Tellers then reported the result of the ballot for officers for the ensuing year, which was of unusual interest because of a spirited contest over one of the offices to be filled. This contest brought out an unprecedentedly large vote. Ordinarily, barely a thousand or less of the membership take the trouble to send in their ballots for officers, but this year 2273 ballots were cast. The officers elected without opposition were: President, Dr. John A. Brashear, of Pittsburgh; Vice-Presidents, George W. Dickie, of San Francisco, James E. Sague, of Poughkeepsie, N. Y., and Henry Hess, of Philadelphia; Managers, Chas. T. Main, of Boston, Max Toltz, of St. Paul, and Spencer Miller, of New York City. To fill the unexpired term of the late Alfred Noble as Manager, the regular Nominating Committee named Morris L. Cooke, Director of Public Works, of Philadelphia. An independent nominating committee, made up of over 100 members of the society, nominated George J. Foran, of New York. Mr. Cooke was, however, elected, the tellers reporting 1171 votes cast for him and 859 for Mr. Foran. The reception to the retiring President and President-elect occupied the remainder of the evening.

It would be impossible within the space available to abstract, even in the briefest manner, the twenty-six papers presented at the various sessions on Wednesday, Thursday and Friday, and the discussion upon them. We can merely refer briefly to a few unusual and noteworthy features of the meeting.

First, comes the preliminary report of the Society's committee on a standard code for steam-boiler construction and installation. The discussion of this report occupied practically the entire session on Wednesday morning, and was carried on thereafter as a separate session, occupying morning, noon and night, until the close of the meeting on Friday. As this code is being prepared for presentation to state legislatures for enactment into law, it is without doubt the most important matter ever brought before the Society, and the careful detail work done by those who faithfully attended these sessions from the beginning to the end of the meeting is deserving of high praise. We have discussed this proposed code further in the editorial columns of this issue.

The second most noteworthy feature of the convention was the special municipal engineering program prepared by the Society's Committee on Public Relations, which occupied the entire day on Thursday. The papers and discussions of this day were not confined to the Society's membership, but were participated in by prominent engineers engaged in municipal service from a number of different cities. The session was made noteworthy by the presence of the Mayor of New York, Hon. John Purroy Mitchel, who delivered the opening address, and also of Andrew Carnegie, whose characteristic Scotch wit was displayed when called upon by the President to address the meeting.

Hon. Henry Bruere, City Chamberlain of New York, discussed the application of the engineering principles to the Police Department, referring to the work of Gen. Bingham in New York City years ago.

Morris L. Cooke, Director of Public Works of Philadelphia, read a paper in which he urged greater public spirit and appreciation of the public interest by engineers in dealing with municipal matters, and appealed to engineering societies for support of measures looking to the increased usefulness of the profession in governmental affairs.

C. E. Drayer, of Cleveland, described the work done by a committee of the Cleveland Engineering Society in promoting greater publicity and public appreciation of the engineer and his work.

At the afternoon session a paper on the "Design and Operation of the Cleveland Municipal Electric Lighting Plant" was read by Frederick W. Ballard, Commissioner in charge of the Cleveland Light Department. This notable experiment in the municipal ownership and operation of public utilities, the largest municipal electric station in the United States, was described in our issue of July 30 last. Mr. Ballard's paper gives, for the first time, particulars as to the engineering design of the station, which involves a number of features of advanced practice introduced with the aim of securing a high economic efficiency. Mr. Ballard also submitted financial figures which on their face indicated that the average price of all current sold by the Cleveland station when it is fully loaded need be only 1.65c. per kilowatt hour generated in order to pay all fixed charges, operating and maintenance costs, and 5% earnings on the investment besides.

These figures were criticised, however, by Alex. Dow, President of the Detroit Lighting Co., and others in the discussion which followed. It appears that the Cleveland station, which has a total capacity of some 25,000 kw., has thus far secured business enough to utilize less than one-fourth its capacity. It was argued that in order to secure the business essential to its economic operation, a much larger amount will have to be invested in the distribution system than that allowed by Mr. Ballard.

Still another noteworthy feature of the municipal engineering session was the report of the committee appointed at the Snow Removal Conference held in Philadelphia, Apr. 16 last. This committee was made up of J. W. Paxton, of Washington, R. B. Hamilton and Wm. H. Connell, of Philadelphia, and John F. O'Toole, of Pittsburgh. The resolutions and plan recommended by this committee follow quite closely the scheme of organization outlined by J. T. Fetherston, Street Cleaning Commissioner of New York, in his campaign for the

coming winter outlined in ENGINEERING NEWS, of Nov. 26, p. 1095.

Other papers scheduled for this session were: "The Handling of Sewage Sludge," by Geo. F. Webster, of Philadelphia; "Training for Municipal Service in Germany," by Clyde L. King, and "Cleaning Filter Sands," by Sanford L. Thompson.

A noteworthy illustration of the extent to which the American Society of Mechanical Engineers is handling the difficult problem of specialization in engineering work is that on Thursday afternoon there were four different meetings in progress at the same time for the presentation and discussion of professional papers. Besides the general meeting above described, held in the main auditorium, devoted to municipal engineering work, the discussion of the Boiler Code Committee's preliminary report was in progress in another part of the building; a session on the fifth floor listened to three papers on metallurgical topics, and a group of those interested in cement manufacture assembled elsewhere to hear a paper on the electric drive for cement mills.

Of the social events in connection with the meeting the most interesting was the award on Wednesday evening of the John Fritz medal to Prof. John E. Sweet, of Syracuse. Members of the four great national engineering societies coöperated in this meeting, and presentation of the medal was made by the President of the John Fritz Medal Board, Gano Dunn, President of the J. G. White Engineering Corporation. Notable addresses were delivered by Dr. James Douglas, past-President of the American Institute of Mining Engineers, and Dr. F. W. Stratton, Director of the Bureau of Standards.

The spring meeting of the Society is to be held at Buffalo.

The First Convention of City Managers

Few in number but strong in the conviction that they represented the beginning of a new and better era in municipal administration, there met in Springfield, Ohio, Dec. 2 to 4, the first convention of City Managers. Springfield and the manager of that city were given the honor of the first convention because Charles E. Ashburner, the chief executive officer of Springfield since the commission-manager plan went into effect there early this year, is the pioneer City Manager, having begun service at Staunton, Va., a number of years ago.*

As there were only eight City Managers at the Springfield meeting, the convention was largely, and happily, informal. There were a number of commissioners and other city officials in attendance, besides other guests.

FORMAL ORGANIZATION
